The exhaust ventilated ben

"We started using ventilated benches several years ago and our experience of them has been most positive. We feel very safe and these benches require much less space and are easier to work with than those large fume cupboards."

Professor Hans Löw, in charge of the endocrinological laboratory at the Karolinska Hospital in Stockholm.

SCIENCE IN INDIA

nature

- *What is to be done about the Indian universities?*
- *Will India's policy of technological self-reliance succeed?*
- *Does the bureaucracy stifle Indian science?*

These and other issues are dealt with in *Nature's* special twenty page supplement on Science in India.
Extra copies of this issue are available now from the address given below.

- Culturing pre-B-cell clones
- Lymphokine inhibition of progenitor cells
- Mechanism of polyadenylation
- Slimming drug receptors
- Bobolink magnetic navigation

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. *Unpublished articles* should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.

FPLC from goes beyond HPLC

Also in biochemistry you want your first results in 10 minutes, a lot of results in a day, and a breakthrough in a week with the high speed and resolution of high performance liquid chromatography (HPLC). In addition you need biocompatibility when separating and purifying labile biomolecules to preserve biological activity and obtain high yields.

The Pharmacia FPLC* system goes beyond HPLC with biocompatible instruments and unique columns of new media designed for high performance

- Enzyme purifications
- Peptide mapping
- Analytical protein separations
- Purification of biologically active peptides
- Separation of oligo- and polynucleotides

The FPLC columns can be repeatedly cleaned, with maintained performance, significantly extending their lifetime. Of course you can also run your traditional columns of Sephadex®, Sepharose®, etc. on your FPLC system.

Pharmacia's experience of 25 years as the leader in biochemical separation techniques is now available to help you discover the full capabilities of high performance chromatography of biomolecules in your laboratory.

*Fast Protein, Polypeptide and Polynucleotide Liquid Chromatography.

ch gives the best protection!

When involved in work without heat sources, i.e. at temperatures below 60° Celsius, the best protection is provided by an exhaust ventilated bench. This has been proved beyond doubt by the Royal Institute of Technology, Stockholm, following comprehensive tests.

Fume cupboards do not normally provide the protection that they should. Wake vortices lead to impurities being sucked out into the atmosphere in spite of the prescribed air flow being applied and the sash being in the correct safety position.

The principle of the exhaust ventilated bench is as ingenious as it is simple. The air is sucked downwards through a perforated working surface, and therefore the main air stream does not pass the analyst. Wake vortices are avoided and the leakage from the exhaust ventilated bench is minimal.

Diagram 1

Leakage from fume cupboard with analyst at work. Measurements conducted by Dr. Sc. Bengt Ljungkvist of The Royal Institute of Technology, Stockholm, using the prescribed air flow, 600 cu. metres per hour and with the sash in the correct safety position with a 27 cm opening.

Diagram 2

Leakage from exhaust ventilated bench with analyst at work. The bench is from Innovent. Diagrams 1 and 2 are comparable. The conditions under which the measurements were carried out were similar. Measurements conducted by Dr. Sc. Bengt Ljungkvist of The Royal Institute of Technology, Stockholm with an air flow of 300 cu. metres per hour.

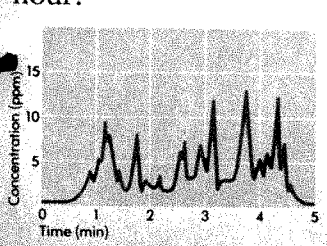

Diagram 1

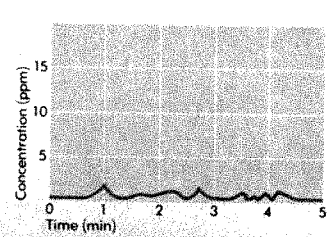

Diagram 2

INCREASED SAFETY AT LOWER COST

For work without heat sources Innovent's ventilated benches using only half the prescribed air flow, provide much better protection than fume cupboards! This means reduced energy costs. In addition the ventilated bench costs very much less than a fume cupboard both in terms of actual price and also installation costs.

Innovent's exhaust ventilated benches can be supplied either in standard specification or they can be specially made. Both alternatives can be supplied with or without hood.

The FRAC-100 Fraction Collector

The FRAC-100 does what any other small fraction collector does – collects fractions, PLUS...

The FRAC-100 *will fulfil all your needs for basic fractionation requirements. As a conventional collector the FRAC-100 is unequaled in performance and reliability. Simplicity in design (3 moving parts) and control (flexible fractionation parameters accessed by a multifunction key board) accomplish fractionation routines previously attainable only with large, expensive instruments.*

The FRAC-100, *as a sophisticated fraction collector presents unique data handling and integration capabilities. The input of a 0–10 mV detector signal is processed by the FRAC-100 to report as a digital display such separation parameters as peak height, peak width, peak retention and peak area. The addition of a PSV-100 solenoid valve enables selective fractionation of only the peak material as judged by a slope detector defined by a programmable threshold value.*

The FRAC-100 – as a small, simple inexpensive fraction collector – your best choice, – as a small sophisticated inexpensive collector, far beyond anything presently available – your only choice.

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING....

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and, ultimately, for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117, U.S.A.

The conference program has been designed for two groups of people – researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: 85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

MONDAY, 10 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 9:30am — 6:00pm

DAY 1
ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00 — 9:15	**Chairman**
9:15 — 10:00	Oncogenes *R. Weinberg (MIT)*
10:00 — 10:45	Growth factors *M. Spom (NIH)*
11.15 — 12.00	HTLV *R. Gallo (NIH)*
12.00 — 12.30	Clinician's view *S. Broder (NIH)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	The cancer cell *J. Cairns (Harvard)*

TUESDAY, 11 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 8:30am — 6:00pm

DAY 2
THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Gene regulation *P. Leder (Harvard)*
10.00 — 10.45	Hereditary cancer *R. White (Utah)*
11.15 — 12.00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12.00 — 12.30	Clinician's view *F. Gilbert (Mt Sinai)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	NCI program

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am — 3:00pm
Recruitment Center: 8:30am — 3:00pm

DAY 3
PROSPECTS AND PROBLEMS — DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10.00 — 10.45	Immunotoxins *J. Uhr (Texas)*
11.15 — 12.00	Drug resistance *A. Varshavsky (MIT)*
12.00 — 12.30	Clinician's view *J. Gutterman (Houston)*
2.00 — 4.00	Round table with morning speakers
4.00 — 4.45	Prospects
4.45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve _____ Conference Registration(s) in the names of: *(Please print or type)*

_____

and _____ Seats at the Tuesday Evening Dinner in the names of:

Attrition, not conquest, of disease

The AIDS saga has been a nasty shock for people accustomed to take modern medicine for granted. The discovery of the virus responsible should remind them of the enduring role of medical research.

AIDS (acquired immune deficiency syndrome) has engendered high drama from the beginning, a mere three years ago. Not every day does a new disease entity pop up, apparently from nowhere. Nor does it often happen that the main foci of a new disease are not in some far-off and half-forgotten developing country but in the most industrially advanced communities in the world. AIDS has shaken the complacency of hosts of people in no present danger of becoming afflicted.

The relatively small numbers of those suffering overtly from AIDS (thousands in the United States, hundreds in Western Europe) have been counterbalanced in people's imaginations by the bizarre features of the condition. People almost always die, but from one of several secondary causes. Most patients have been homosexual men, but women and their newborn children as well as people receiving blood transfusions and factor VIII (in haemophilia treatment) have been affected. This has raised alarm that whatever agent may be responsible is confined to those now afflicted only fortuitously — and temporarily. The notion, increasingly plausible in recent months, that the agent responsible is most probably a virus has been particularly shocking for smug health-ridden societies long since persuaded that medicine is a routine technology, even a physicians' ramp, and that good health is either a consumer purchase or an attitude of mind. Was not infection abolished with penicillin, anxious people have been complaining?

The latest instalment of the AIDS drama should give the lie to many of these nonsensical expectations. AIDS is almost certainly caused by a virus, that most clearly characterized by Robert Gallo and his associates at the National Cancer Institute in the United States, but with a high chance that the virus previously described by Luc Montagnier at the Pasteur Institute in Paris is identical. Both are retroviruses carrying genetic information as RNA, a DNA version of which becomes incorporated into the genes of infected cells. The most telling evidence is that a majority of the patients with AIDS carry antibodies against one of the viral proteins — at some earlier stage, their immune systems have responded to an infection which has nevertheless overwhelmed a large proportion of them. But as yet, little is known of the mechanism of infection, of the reasons why one class of T cells among lymphocytes is put out of action by the virus or of the status of those who have already been infected (to judge from the antibodies they carry) but who have not developed symptoms of AIDS. (The haunting question is whether they are immune or destined to run into trouble.) And next to nothing is known of the natural history of the virus. So why, the sceptics will be asking, is there all this fuss? If neither Gallo nor Montagnier can offer a cure, what benefit is there in what they have accomplished?

Virus

The simplest answer is also primitive. AIDS, a mystery only a few weeks ago, has been transformed into another virus disease. And that transformation, even though it will not by itself prevent the death of a single patient, has the utmost practical importance. Correspondents this week (p.12) and last have explained what steps can now in principle be taken — the identification of those among the sexual partners of AIDS patients who have been exposed to the virus (and who may or may not be carriers or at risk themselves), the screening of transfusion blood (if practicable) and so on. The essential tools for these investigations are the standard techniques of pre-molecular immunology. So AIDS has been lumped in the same category as, say, measles.

The same techniques will play a crucial part in helping to unravel the natural history of the disease (and the suspected link with central Africa) — as will the mere knowledge that a virus is indeed responsible. The only practical benefit certain to flow from what will now happen is that some people at risk will be helped to avoid infection. But the conversion of a mystery into a medical problem will also provide people with a sense of confidence that would otherwise not have been supportable. What has happened with AIDS is yet another illustration of the well-known truth that to know the cause of a problem is a necessary part of its solution.

Control

But when will there be a vaccine to prevent the spread of AIDS, or even a way of curing those already infected? That is what public health officials need, and what many of their constituents will insist can alone count as progress. The again maddeningly simple answer is that nobody can tell. It has taken fifteen years from the recognition of the then-surprising life-cycle of the hepatitis-B virus to the development of vaccines (now going into trials) whose efficacy is not yet known. AIDS is only the second human disease known to be associated with a retrovirus — the other is adult T-cell leukaemia, first recognized in south-east Japan — and the obvious ways of going about the job of vaccinating against AIDS could yet prove ineffective. The prospects for more effective treatment for patients already stricken are even less certain (although not necessarily more distant). But when the causes of death in AIDS are the accidental infections patients pick up and the otherwise rare skin cancer called Kaposi's sarcoma, and if the reasons for these developments are the known deficiency of helper T cells in patients' blood, the only guarantor of more effective treatment is the better understanding of the human immune system at which literally hundreds of laboratories have set their sights. (It will be sheer good luck if the trials with the genetically engineered humoural agent interleukin-2 also now being mounted turn out to be successful.) Like it or not, those who look for quick results must cultivate patience instead.

Those to whom that advice is unpalatable should reflect that things might be much worse. Montagnier's observations, reported last month (*The Lancet* **i**, 753; 1984), turned on the lucky accident that of two haemophiliac brothers being treated with factor VIII, only one had developed overt AIDS when first seen. Gallo's investigation, based on samples from many more patients, was a natural extension of his group's interest going back for four years in human T-cell leukaemia virus, type I of which may or may not be the same as that responsible for adult T-cell leukaemia in Japan. Here again, however, it is good luck that Gallo's group is now well placed to apply to the further definition of the AIDS virus the techniques of genetic manipulation being vigorously applied to the understanding of the role of retroviruses and oncogenes in carcinogenesis. In other words, the understanding of AIDS that has now been wrung from a seemingly obdurate problem is striking proof of the value of the basic biomedical research on which people have for decades enthusiastically lavished their talents — and governments, less

sure of themselves, their resources.

In these terms, rapid demonstration that AIDS is indeed caused by a virus is a triumph, even if not quite the "triumph over disease" that Mrs Margaret Heckler, the US Secretary of Health, described it last week. The triumph is that the research community has been able to respond so quickly to an unexpected development such as the emergence of AIDS. The explanation is again simple, exasperatingly so — the richness and diversity of the biomedical research enterprise, in the United States in particular but also throughout the world.

More good luck? Almost certainly not. The chances are high that in the present pattern of medical research, there would have emerged some group of workers somewhere in the world able — and willing — to turn from its long-term interests to throw light on a medical emergency such as that which cropped up three years ago. This is exactly what happened a decade ago with Legionnaires' disease, in its time also a threat to people's peace of mind. None of this diminishes the importance of what Montagnier and Gallo have separately done although, with both Legionnaires' disease and AIDS, the work done by the Centers for Disease Control at Atlanta, Georgia, deserves widely to be applauded. (So too does that of the clinicians who, in the past three years, have been required to treat AIDS patients with forms of therapy offering palliation only, who have in the process courageously taken to unprecedented lengths the openness and compassion that ideally characterize relationships between physicians and their patients and whose services in this regard will unhappily be required for many years to come.)

The moral, for Mrs Heckler as well as for the impatient sections of advanced communities eager to indulge the luxury of pretending that the practice and the pursuit of medicine have long since been replaceable by suitable doses of orange juice, physical exercise and mental application, is that the deliberate provision of medical care is in one important sense only a little more certain now than, say, a century ago. By means of large and costly social expenditures in research laboratories and clinics, the incidence of avoidable death is kept at a socially acceptable low level, but there is no avoiding the hazards still unknown. The best that can be done is to be prepared to deal with these hazards quickly, as they declare themselves. The case of AIDS has triumphantly illustrated the versatility of the biomedical research system patiently put in place in recent decades. Successive US governments have been especially farsighted in recognizing the importance of such a development. It is to be hoped that this latest emergency will help to win wider acceptance of the value of a vigorous research enterprise. For there is no prospect of a triumph over disease in general. □

Double-talk on animals

NIH seems more ready to risk its reputation than to meet serious critics on animal care.

ANTIVIVISECTIONISTS and other crusaders have never made intellectual integrity one of their top priorities. Appeals to emotion, however inconsistent or however specious, continue to be the hallmark of those who wish to halt animal experiments. So it is no accident that cute animals — preferably those with a lot of fur — star in the antivivisectionists' advertising campaigns (which have now reached the underground railway system in Washington, DC, in the form of posters of a child with a dog and a message that scientists who have perfectly reasonable alternatives to animal experimentation are hoping to make that dog suffer).

The National Institutes of Health (NIH), which support the majority of animal experiments in the United States, have now apparently decided that they too can play that game. At the first of what will be a series of meetings around the country, NIH produced for the public's heartstrings real-life patients and their families who have benefited from animal experiments. While the sincerity of what these patients had to say is indisputable, one has to feel uncomfortable at the exploitation of their misfortune inevitably at play when the federal government stands them up to say how much they love their husbands and how grateful they are that medical research has kept their children's daddies alive.

One has to feel even more uncomfortable at the nagging suspicion that NIH's simultaneous announcement of a new and supposedly tougher set of rules for the care and use of laboratory animals is nothing more than a part of this same public relations campaign. This conclusion can only be reinforced by NIH's simultaneous release of a study of animal experimentation at ten research institutions, chosen at random, that finds the old rules are working fine and that there are no problems to correct. If so, why correct them, unless the aim is to make a — very public — point?

In reality, the new regulations, which are published as a proposal open for public comment, do very little. Research institutions under the new regime will not only have to "commit themselves to implementing" animal care requirements — they will now have to "implement" them, a major crackdown if there ever was one. The only substantive change in the proposal is that the institutional animal care committees, charged with monitoring the use of laboratory animals at each research institution, would have to include one outside member.

NIH director James Wyngaarden set the tone for the NIH stance when, at last month's meeting, he declared his "deep concern" that public support for laboratory experiments involving animals may be eroding, the result of "politically sophisticated critics" who are attacking animal experiments as unnecessary and inhumane. NIH arguably have a role in public education to counter this trend, but need not sacrifice integrity in the process. If "political sophistication" means issuing meaningless regulations for the sake of appearances, NIH are better off with naivety. Or is it that by invoking the bogey of rabid antivivisectionists seeking to shut down biomedical research, NIH hope to distract attention from some serious proposals for reform (as opposed to revolution)?

It taxes credulity to claim that the extreme "animal rights" positions inherent in the antivivisectionists' stance are about to sway the overwhelmingly carnivorous population of the United States, or indeed that they are more than a sterile pseudo-philosophical exercise. A much more serious threat to present practice is not the crazed antivivisectionists but, rather, some sensible criticisms from sensible people. Senator Robert Dole, for one, has introduced legislation that, while respecting the absolute freedom of researchers to design scientific protocols and to make their own judgements on the necessity of using animals, would clamp down on some of the more serious persisting abuses in the care of laboratory animals and their use. The bill would require the use of analgesics, tranquillizers and anaesthetics except when scientifically impossible, would forbid the use of the same animal in more than one major operative procedure and would require either proper postoperative care or prompt euthanasia. Enforcement would be left largely to the animal care committees, which would have to certify in regular reports that experimental procedures involving animals followed these requirements. Significantly, the bill does not limit the freedom of scientists to proceed with such experiments; it does, sensibly, require that investigators "consider" alternatives and consult with a veterinarian in planning procedures involving unanaesthetized animals.

There is hardly anything subversive about these proposals. (Nor is there anything subversive in demands of animal welfare activists, such as Mrs Christine Stevens of the Animal Welfare Institute, that inspections now required by federal law should actually be carried out to ensure that laboratory animal care meets the published guidelines — which means basic things like clean cages, proper food and proper ventilation.) The US Department of Agriculture, which is charged with carrying out the inspections, has never been given the funds to discharge its responsibilities under the law. Yet such inspections as it is able to carry out reveal continued problems in these basic necessities for humane care. NIH would do well to face up to these issues, rather than issuing pronouncements full of sound and fury that signify nothing. □

Star wars

Pre-election Congress turning sour

Washington

THE militarization of space may yet become a significant issue in November's presidential election in the United States. For the first time, Mr Walter Mondale, the Democratic front-runner, last week promised to order a freeze on space weapons if he is elected President. In Congress, meanwhile, even the Republican Senate is alarmed about President Reagan's desire to press ahead with deployment of anti-satellite weapons and research on a "star wars" defence against nuclear missiles. Dr George Keyworth, the President's science adviser, was given a frosty reception when he told the Senate Foreign Relations Committee that he opposed negotiating a ban on space weapons lest it blocked the star wars programme.

Congressional anxiety can only have been heightened by the publication of a report by its own research arm, the Office of Technology Assessment (OTA), concluding that the prospect of creating a near-perfect defence is "so remote that it should not serve as the basis of public expectation or national policy". Although detailed criticisms of the star wars plan have been published before — most recently by the Union of Concerned Scientists — the new OTA study is the first to be published by a neutral body with full access to classified information. Its pessimistic conclusions are likely to have considerable influence on the mood of Congress.

The report, prepared by Dr Ashton Carter of the Massachusetts Institute of Technology, covers largely familiar territory by drawing attention to the difficulties of propagating directed energy weapons with the range and accuracy to knock out a large-scale nuclear attack, and pointing out that for every defence concept proposed so far, simpler and usually cheaper countermeasures have already been identified. One of the most forthright parts of the report, however, points to four common "misapprehensions" about the prospect for a perfect defence. They are:

- Confusing the successful development of single devices — lasers, mirrors, aiming mechanisms and the like — with the creation of a successful system. Multiplying by even a million some directed energy weapon will not necessarily give a perfect defence.
- Equating star wars with past technological challenges, such as the Moon landing or the Manhattan Project. The report notes a "vital difference" between working around constraints imposed by nature and competing, in the case of star wars, with a hostile intelligence bent on sabotaging the effort.
- Hoping for a technological development that will dispel all difficulties; when perfection of the X-ray laser for example, might turn out to benefit offence more than defence.
- Expecting to know with reasonable confidence how a complex defensive system would perform in reality. Unlike defences used in previous wars, this one would have no chance to learn or adapt.

OTA concedes that it might make sense to construct a star wars system even if it is less than perfect, in order, for example, to protect missile silos or simply to protect as many lives as possible. But it complains that, despite the fanfare with which President Reagan's star wars proposal was announced, its precise aims remain unclear. For that reason, explicit standards against which its technical feasibility can be measured have proved elusive.

Genetic engineering

Genentech claims factor VIII

ONE of genetic engineering's glittering prizes was claimed last week by Genentech Inc., the San Francisco-based biotechnology company, working in collaboration with the Haemophilia Centre at the Royal Free Hospital Medical School, London, and Speywood Laboratories in Wales. The human blood protein known as factor VIII, which is lacking in haemophiliacs and essential for their treatment, has now been cloned and expressed in biologically active form in a mammalian cell culture. The availability of a completely sequenced cDNA clone for factor VIII, the largest protein ever produced through recombinant DNA technology, is an essential first step towards a source of the factor that is independent of supplies of human blood plasma and so not susceptible to contamination by viruses.

Most factor VIII used in Britain is prepared from concentrates that may contain the pooled plasma of up to 20,000 blood donors. All such concentrates are infected with hepatitis viruses and many haemophiliacs suffer from liver dysfunction caused by non-A and non-B hepatitis. Existing alternative production methods may lead to a lower risk of contamination but have their own disadvantages. Haemophiliacs are also a high risk group for acquired immune deficiency syndrome (AIDS), almost certainly because an AIDS virus can contaminate factor VIII produced from plasma. It has been clear for the past three years that any replacement of comparable efficacy would be assured of a huge market.

The Haemophilia Centre in London developed a method of obtaining factor VIII in high purity using monoclonal antibodies to the protein and established the gross structure. At Genentech, a genetic probe derived from a factor VIII subunit was used to test genomic libraries until a clone was identified that matched one possible predicted DNA sequence. The factor VIII gene turns out, as expected, to be located on the X chromosome. Eventually a clone of the complete gene was obtained (190 kilobases long) and a cDNA clone of factor VIII produced. After transfection of the clone into a mammalian cell line (Genentech will not say what type), human factor VIII was detected in the culture medium and measured by a purified enzyme system. The activity of the material is quenched by monoclonal antibodies to human factor VIII — further evidence that factor VIII is being produced.

Genentech is at pains to point out that there are several years' more work ahead before factor VIII will be produced by genetic engineering on a commercial scale, though it hopes to produce enough factor VIII for clinical trials of the product (probably around 100 mg) within 2 years. The aim now will be to obtain a cell line able to sustain high output of the protein and which can also be cultured on a relatively large scale. Last week's announcement preceded any publication of the genetic discoveries in a refereed scientific journal, but both Genentech and the team at the Haemophilia Centre in London say that papers are planned.

Naturally, nothing is as yet known of the economics of factor VIII production by genetic manipulation. There are, however, about 20,000 users of factor VIII in the United States, and as many again in Western Europe. Supplying known needs would be worth sales of at least $100 million a year. Knowing how to manipulate large molecules such as the components of the blood-clotting system will be worth much more to the company which first succeeds in making such materials.

The announcement last week will be a blow for several other biotechnology companies working on factor VIII. Previously, only parts of the gene had been sequenced. Genentech says it intends to protect fully the processes it has developed by patents, and a spokewoman added ominously that the company had recently expanded its patent staff. But the usefulness of patents in protecting biotechnology processes generally is not yet established, and one disgruntled competitor summed up his feelings by saying "better late than never".

Cancer research

Direct-mail medicine criticized

Washington

A NEW organization created to raise funds in the United States for studies of diet, nutrition and cancer is coming under fire for spending only a small proportion of the millions collected through direct-mail solicitations on actual research. The American Institute for Cancer Research, founded in 1981 by two professional fund-raisers in the Washington area, took in some $3.5 million during its first fiscal year ending September 1983, while awarding only $400,000 in research grants.

According to a financial disclosure filed with New York State on 16 April this year, $600,000 was spent on public education and $2.4 million on fund-raising. And a report issued last month by the Council of Better Business Bureaus (BBB), an independent group that monitors charities and investigates consumer complaints, revealed that $893,000 of the institute's fund-raising expenditure went to the firm owned by the institute's founders, Jerry Watson and Chat Hughey.

The BBB report concluded that the institute failed to meet its standards for charitable solicitations, which require that at least half of the funds raised be applied to the programmes described in the organization's public appeals. The BBB standards also require that the organization should have an independent governing body.

Since the end of the fiscal year, the institute has made some changes to correct these deficiencies, notably by amending its by-laws to restrict the founders' rights to appoint or remove directors of the institute.

A spokeswoman for the institute said that New York State, which has the strictest disclosure laws in the country, included under "fund-raising" close to a million dollars in expenditures that the institute considers to be "public education" activities, such as the printing of newsletters. According to an audit commissioned by the institute itself, only 37 per cent of its receipts went on fund raising. The New York rules consider an activity such as mailing a newsletter to be fund-raising if it is combined with an appeal for funds and if fund-raising is the "primary purpose".

The direct-mail pieces that the institute is continuing to send out, however, have raised the hackles of many scientists, the American Cancer Society and, according to a report in the *Los Angeles Times*, the state attorney general's office in California. More than 11 million copies of a "Census on Diet and Cancer" were sent out, which combines on a single page questions such as "what vitamin supplements do you take?", "do you eat red meat at least three times a week?" and "have you ever had cancer?" with a "contribution reply" that offers the opportunity to make a tax-deductible contribution. Respondents are asked to tick a box that reads: "I agree! It's absolutely essential to do extensive research in the area of diet and cancer — especially now when it's estimated that 50 per cent of all cancer is diet-related."

The institute's spring 1984 newsletter quotes letters from enthusiastic donors, including such comments as "unfortunately medical schools appear to completely overlook (*sic*) the importance of proper nutrition in maintaining good health" and "I firmly believe . . . that many illnesses can be prevented, halted, and even cured by proper diet".

Dr Colin Campbell, a Cornell University biochemistry professor who served on the National Academy of Sciences panel on diet and cancer, was named senior scientific adviser to the institute last December. He acknowledges that the "census" continues to make him "uncomfortable" and that it is of virtually no scientific value. He said he had told the institute staff that it was unacceptable but had rewritten the questions to make them "neutral" at least. He said he had also rewritten a cover letter to make it less "scary" and more positive in tone, and the institute's fund-raisers had agreed to try it, although he said they had told him they were not sure it would work. The original letter had said "Cancer can strike you, your parents, your brothers and sisters — anyone".

Campbell said he had instituted a new process for reviewing grant applications modelled on that used by the National Institutes of Health study sections, and was taking steps to advertise the availability of grants. Until now, the availability of the funds had been spread only by word of mouth. Although the institute does not release the names of its seven-member review panel, a list obtained by *Nature* confirmed Campbell's assurances that they are all reputable research scientists.

Campbell said he felt it unfair to judge the institute harshly on its performance during its first year of operation. The spokeswoman said the institute hopes to disburse 20 per cent of its funds in research grants this year. And she cited as an example of the institute's activity in public education the mailing of 20,000 copies of the National Academy report to physicians and the distribution of one million cards on breast self-examination for women.

In addition to the $400,000 in grants made last year, a further $700,000 had been committed and is being paid out, according to Campbell. Campbell's new review panel met in March and approved a further nine research proposals. The largest recipients of the awards made last year were the Linus Pauling Institute ($70,000), the American Health Foundation ($50,000) and Theodore Krontiris of Tufts University ($50,000). Three members of the scientific panel, including Campbell, have also received grants. **Stephen Budiansky**

NIH to bolt the stable door

Washington

A NEW study by the National Institutes of Health (NIH) has recommended tighter procedures at their clinical research centres to prevent a recurrence of the Darsee affair. Dr John Darsee, who had been widely regarded as a brilliant young medical researcher at both Emory University and later at Harvard University, was found to have repeatedly fabricated research results.

The NIH study of Darsee's activities at the Emory General Clinical Research Center, one of 75 such centres supported by NIH, concluded that trainees should be supervised more closely and that co-authors of scientific publications should be required to accept responsibility, in writing, for the papers.

The study offered no recommendations specifically for Emory, noting that the university had taken action on its own to prevent a repetition following its internal investigation of the Darsee affair. A major weakness cited by the NIH investigation was the absence of procedures at Emory at the time to detect Darsee's unauthorized inclusion of faculty members as co-authors on his many publications and abstracts — and the failure of even witting co-authors to detect anything suspicious about Darsee's research results. The investigators were told that although the chairman of the department of medicine at Emory did routinely review all manuscripts produced by the department, his review was "primarily intended to insure that supporting grants and services are acknowledged correctly".

The recommendation for closer supervision of trainees arose from the investigators' discovery that the Emory faculty members with whom Darsee collaborated each assumed that another faculty member was supervising Darsee's clinical studies. The NIH study recommends the naming for each young investigator of a single supervisor who would be expected to review regularly the trainee's clinical studies, including raw data.

The NIH investigation was conducted by Drs Evelyn Hess (University of Cincinnati), Darryl DeVivo (Columbia/Presbyterian Medical Center) and James Freston (University of Connecticut). Its recommendations are now being considered by the NIH Division of Research Resources, which administers the clinical research centres.

Agent Orange

Veterans' case comes to court

Washington

THE complex saga of Agent Orange, 11 million gallons of which were sprayed on Vietnam between 1962 and 1971, will finally come to trial before a federal court in Brooklyn, New York, on 7 May. A jury will have to decide whether the chronic health problems of nine plaintiffs, including five veterans and three children born with catastrophic birth defects, were caused by exposure to dioxin contaminant tetrachlorodibenzodioxin (TCDD) found in the herbicide. A huge amount of money is at stake; the plaintiffs represent the entire class of veterans and families who attribute medical problems to exposure to Agent Orange. Damages awarded against the companies concerned could amount to thousands of millions of dollars.

Although the class action is directed principally against seven manufacturers of Agent Orange, the federal government is expected to be in court too — very much against its will. The manufacturers, claiming that the federal government knew about the possible health effects of the defoliant when it used it, have filed third-party complaints that could force the government to share in any liability. The courts have so far rejected the government's claim that it cannot be sued for injuries received during military service.

The question of who knew what about Agent Orange, and when, will be a central issue in the trial. One of the allegations made against the manufacturers is that one of them, the Dow Chemical Company, was worried about the toxicity of dioxin as early as 1965, but tried to hide its concern from the federal government. Dow vigorously denies the charge. It says its worries in 1965 concerned the exposure of its employees to large concentrations of TCDD during manufacture, not use of the finished product which contained vastly lower concentrations. It also maintains that the Department of Defense knew at least as much as the manufacturers about the components of Agent Orange and the toxicity of TCDD.

But Dow and its co-defendants intend to base their defence on scientific arguments. They maintain that not enough research has yet been done to conclude whether the health of Vietnam veterans and their families differs significantly from that of the rest of the population. The evidence that is available, they argue, suggests that Agent Orange could not have caused the health problems ascribed to it.

Information about the effect of TCDD on humans is indeed sparse, although Congress has occasionally rapped the American Medical Association over the knuckles for saying so. Most of the data available have come from studies of industrial accidents, where victims are typically subjected to high exposures for short periods, not to low exposures over a long period as in the case of troops in Vietnam. Even so, the only TCDD-related disorder about which there is no argument is chloracne, the skin disease.

Preliminary studies of the impact of Agent Orange have so far failed to establish a clear link between the herbicide and the many disorders — including birth defects, lymphoma, neuromuscular weakness and liver enlargement — for which it has been blamed by veterans. The scientific evidence has been further muddied by the findings of the Air Force's own epidemiological study of the personnel involved in the "Ranch Hand" operation, as the herbicide-spraying operation was called. The Air Force reported in March that there was little evidence that the Ranch Handers had suffered as a result of contact with Agent Orange. None had soft-tissue sarcomas or chloracne, although the incidence of certain birth defects, skin cancer and liver disorders was high.

Like many other studies of Agent Orange, the Ranch Hand results have been hailed as a victory by both sides in the dispute. The Dow Chemical Company points out that the skin cancers could have been caused by exposure to sunlight; the veterans' lawyers said the study showed that science was beginning to "catch up" with what the veterans already knew — that Agent Orange damaged their health.

The Ranch Hand study, however, is only one of more than 60 federal studies of the effect of dioxin being conducted at a cost of some $100 million a year. Because the number of Ranch Hand personnel was small, the study was not expected to be sensitive to rare illnesses, a point made forcefully by a National Academy of Sciences review of the Ranch Hand protocol in 1980. Meanwhile, a major research programme, including a study of identical twins of whom one brother served in Vietnam, is under way within the Veterans Administration.

At congressional insistence, however, the Veterans Administration has had to transfer responsibility for a major epidemiological study of veterans to the Centers for Disease Control (CDC) in Atlanta. The Veterans Administration is distrusted by veterans and has been accused repeatedly of reacting slowly and insensitively to veterans' anxieties about their health. The $70 million epidemiological study will be the biggest ever conducted by CDC. Some 30,000 veterans will receive a detailed health interview and another 10,000 will be given extensive two- or three-day physical examinations in what CDC hope will become the definitive analysis of the Agent Orange question. But the results will not start to emerge for at least seven years, too late to help the Brooklyn jurors in May. **Peter David**

Chinese nuclear industry

Advance on broad front

DISCUSSIONS on a possible $20,000 million deal in nuclear technology were a major feature of President Reagan's visit to China last month. Coincidentally, the President's visit came shortly after the second national congress of the Chinese Nuclear Society, which reviewed the current state of Chinese nuclear technology and explored ways and means of "uniting and organizing" large numbers of scientists to meet the challenge of the nuclear age.

Addressing the inaugural session of the congress, Defence Minister Zhang Ai-Ping noted that although China has built a "fairly comprehensive" nuclear expertise over the past 20 years, and has started construction work on its first nuclear power station, at Taishan, the application of nuclear technology to the economy has been neglected. Satisfying the needs of "economic construction and improving people's standard of living" must, he said, be a priority for the nuclear industry, although it must also "ensure the satisfaction of military needs".

In fact, considerable progress has already been made on the applications of nuclear technology. More than 1,700 nuclear radiation instruments are now used in the textile, printing, paper-making, plastics and petrochemical industries. Between four and five thousand oil wells have been logged by radioactive methods, radiation sand-gauges have been installed in 12 hydrometric stations along the Yellow River to monitor sand content of the water and tracer techniques used for safety surveys of reservoirs.

Future plans include two more nuclear power stations (one in Zhejiang Province and one in the Shenzhen Special Economic Zone) and two 450-MW combined heat and power units for the Jinshang petrochemical works in Shanghai. Feasibility studies are in progress for urban central heating systems. According to Jiang Xinxiong, the Minister of the Nuclear Industry, China plans to be self-sufficient in nuclear fuel by the end of the century, while experimental work on fast breeder reactors and controlled thermonuclear fusion is "making progress".

The main problem, according to Defence Minister Zhang, is, however, safety, and, at the same time, popularization of knowledge about the peaceful use of nuclear energy in order to dispel "misgivings and apprehensions". The Chinese nuclear industry, Zhang said, is quite capable of handling fuel reprocessing, but should go on improving facilities and techniques in this field. Some experts believe that it could also undertake reprocessing on a commercial basis for other countries. **Vera Rich**

Australian technology

Jones and Hawke make hay

Canberra

THE restructuring of Australian industry in the face of rapid technological change has become a central policy theme of the year-old Labor Government, due in large measure to the advocacy of the Minister for Science and Technology, Mr Barry Jones. The Prime Minister, Mr R.J. (Bob) Hawke, has set up a committee of federal ministers to coordinate policies relating to the many deep structural changes necessary. As well as Mr Jones, the committee includes the Ministers for Trade, Education and Youth Affairs, Industrial Relations and Defence Support, under the chairmanship of Senator John Button, Minister for Industry and Commerce.

On 13 April, Mr Jones released a draft national technology strategy to stimulate Australia-wide discussion of structural problems. His paper, a summary of deliberations of the National Technology Conference last September, contains several proposals crucial to the transformation of Australian productivity. It is particularly concerned with the minuscule investment in research and development by private industrial companies. According to the figures made available, research and development in Australia in 1981–82 hit a low of 1 per cent of gross national product (GNP), with the business sector's contribution sinking to 0.2 per cent. In 1968–69, private research and development was 0.5 per cent of GNP in a national total of 1.3 per cent.

The paper now sets a target of 1.5 per cent of GNP overall for 1990, with the business share amounting to 0.5 per cent and rising to 1.0 per cent by 1995 to equal the government's projected contribution.

Much of the blame for Australia's dismal export performance in technology was attributed to the country's attitude to education as an investment. The Jones strategy now urges that the proportion of Australian children completing secondary school be increased from 30 per cent in 1982 to 40 per cent in 1985 and 50 per cent by 1995. Alarmingly, the number of tertiary students between 17 and 22 years old actually fell, as a proportion of the population of the same age, from 11.5 per cent in 1975 to 10.5 per cent in 1982. The strategy paper's recommended figures for 1985 and 1995 are 12 per cent and 20 per cent respectively.

Many of the recommendations in this paper are politically sensitive, including the proposal for a review of union attitudes to adult apprenticeships, the effect on training of minimum wages for juniors and the previously sacrosanct doctrine of "comparative wage justice" in which "equal work" attracts equal pay regardless of the industry or its capacity to pay. One per cent of the workforce should be retrained each year, a portable superannuation scheme instituted to promote mobility between industry, universities and government, and industrial protection gradually reduced.

In a society arthritic with structural rigidity, with 50 per cent of the workforce unionized and a cadre of industrial managers not yet weaned from protectionism, the issues canvassed are strong meat. The prosecution of the policy implied will depend on Mr Hawke's skill at maintaining consensus.

An admirer of South-East Asian industrial development and a recent convert to economic planning in the style of the Japanese Ministry of International Trade and Industry (MITI), he claims that previous governments have not been interested in formulating coherent science and technology policies. **Jeffrey Sellar**

European pharmaceuticals

Free trade makes trouble

A BRITISH Medical Association (BMA) campaign aimed at preventing patients from being dispensed unlicensed drugs has suffered a temporary setback. The newly-formed Association of Pharmaceutical Importers claims that BMA's advice to physicians last week to stamp prescriptions "UK-licensed products only" contravenes the Treaty of Rome.

BMA's general medical services committee had become concerned by the growing number of reports of adverse reactions to imported drugs that are dispensed in the same ways as UK brands but which have not been licensed specifically for the UK market. Imported products bearing the same name as home lines may include differently coloured tab-

Radioactive atolls

Bikini Islanders sue United States

Washington

THE inhabitants of Bikini Island, which was used for 23 above-ground nuclear tests between 1946 and 1958, are suing the US Government in an attempt to force a clean-up of their homeland. The 167 residents of the island left at the request of the US military and have since been shifted several times to different nearby islands, living largely on food and supplies provided by the US Government.

A study commissioned by Congress reported last fall that a clean-up could be carried out at a cost of $90–120 million.

The most feasible approach, according to the study team headed by Harvard professor emeritus Henry Kohn, would be the removal of a million cubic metres of contaminated topsoil. Without such drastic measures, the island would not be habitable for 100 years if local foods were to be consumed.

The urgency of the suit filed this week, according to the islanders' attorney Jonathan Weisgall, is that the Compact of Free Association approved by the Marshall Islanders (of which Bikini is a part) and now pending before Congress would terminate all claims arising out of the nuclear testing, and would provide no funds for cleaning up Bikini. The Bikini Islanders would, however, receive $75 million in compensation over the next 15 years on top of the $23 million trust fund already set-aside by Congress. This fund is used to pay medical and other expenses and a monthly stipend to the 1,100 islanders and their descendants.

Eniwetok, an island near Bikini also used for nuclear testing in the 1950s, was cleaned up by the United States in the 1970s at a cost of $105 million.

The Bikini atoll had been resettled after the Atomic Energy Commission (AEC) reported in 1967 that radiation had diminished to a safe level. In 1975, however, an initial ground radiological survey raised doubts about AEC's earlier conclusion; and a full survey in 1978, which included measurements of body-burdens of radiation in the 139 Bikini Islanders who had returned, found that they were receiving exposures of 0.27 to 1.18 rem per year, largely from eating locally-grown food that had taken up radioactive caesium-137 from the soil. The federal standard for the general public is 0.5 rem per year; the occupational limit is 5 rem per year. Those who had resettled were removed once again, and the island has since remained uninhabited.

As well as taking legal action, the islanders are appealing to Congress for action on a clean-up; the House Interior Committee has recommended an initial $10 million authorization to begin the work.

Stephen Budiansky

lets and dosages, differently worded instructions (sometimes not in English) and may even be of different formulation or make-up. Its recommendation to physicians was intended to counter this trend.

BMA's advice is heartily endorsed by the Association of British Pharmaceutical Industry. British manufacturers estimate they lost £75 million last year to "parallel imports", bought from their overseas divisions and sold in Britain considerably below the standard British price. The price differentials are a consequence of the varied methods for regulating pharmaceutical companies in different countries. In Britain, overall profits are limited under the Pharmaceutical Prices Regulation Scheme, which specifies a target profit band for each company, based on capital employed, and also controls advertising expenditure. In other countries, prices or profits may be controlled individually for different products.

The European Court of Justice ruled in 1976 that parallel importing should be facilitated and that restrictions would be in breach of freedom of trade, but in 1980 an attempt by the commission to introduce a directive legitimizing parallel importing failed. The new pharmaceutical importers' association justifies its present imports by citing a British licences exemption order intended to apply "in circumstances in which small quantities of medicinal products are imported into the United Kingdom for the treatment of particular patients".

Even though advertising of products imported under this order is illegal, the Department of Health has been unwilling to take action against infringements, fearing it would be dragged through the European Court. A new statutory instrument that will permit advertising of parallel imports and comply with the European Court's ruling while retaining some controls is now being finalized by the Department of Health and will be laid before Parliament in a few weeks' time.

A spokesman for the parallel importers accepted that British patients had in the past been dispensed products other than those their physicians intended, but said the association will encourage its members to "put their houses in order". Recently, some of its members were obliged to give an undertaking in the High Court to stop passing off as the UK version an imported Glaxo product with deliberately counterfeit packaging.

At issue now is whether a voluntary professional association such as BMA can make recommendations to its own members without contravening European law. BMA says it took full legal advice before making its recommendations to physicians and is confident of their legality. The question now seems likely to be answered in court, and BMA has halted its campaign until the issue is resolved to its satisfaction.

Tim Beardsley

China in space

Triumph and martyrdom

CHINA'S space planners last month released details of the setbacks and disasters suffered during the nine-year effort to put into synchronous orbit an "experimental" communications satellite. The satellite was successfully launched on 8 April, and inserted into its final orbit at 125°E on 16 April.

The admission on Chinese radio that a number of "scientific and technical workers" had "laid down their precious lives" during the development of the satellite was clearly intended as part of the current drive against "anti-intellectual" prejudice still persisting from the Cultural Revolution.

The broadcast centred on two major examples of heroism. One, a lone martyr, Ma Jungyan, had been working on the possible effects of solar radiation on a satellite in orbit. As this was during the "chaotic time of the Gang of Four", Ma was obliged to carry out simulated experiments at the atomic energy research institute without even the "minimum safety protection". He was, said the commentator, fully aware of the danger but "knowing that there was a tiger in the mountains, he still headed towards them". As a result, he developed a serious radiation-induced lung condition, but during every remission continued to "work frantically".

The other incident was the explosion of a rocket on 28 January 1978, during tests on fuel flow. Seven of the research team, including the director of the test-pad, were seriously injured and several others suffered burns and ruptured eardrums. Nevertheless, at the urging of the injured director, a party meeting was held the same afternoon to determine the cause of the incident, and testing was back to normal three days later. A week after the incident, the director and "several other comrades" were back at work, still in bandages, and they returned to the hospital to complete their treatment only when the experiment was finished.

It is not clear whether there were any deaths in this incident; the commentator clearly implied, however, that there had been several fatalities on what he called the "battlefield" of the space programme, the programme of the rocketry division. Whether Ma Jungyan and his fellow martyrs will receive public recognition in the forthcoming exhibition on the Chinese space programme, which opens in Shanghai later this month, has not yet been revealed. But China seems bent on being open.

Vera Rich

Unesco

Looking for signs of change

FURTHER signs of the response of Unesco (the United Nations Educational, Scientific and Cultural Organization) to the discontent of some member states should become apparent next week, at the meeting of the organization's executive board arranged for 9–23 May. Those participating in the meeting expect that decisions about the budget for 1985, when the US notice of withdrawal will have expired, cannot be taken until the meeting of the executive board due in November. But next week's meeting should throw some light on Unesco's response to the British Government's for radical changes in the organization's way of working.

The agenda for next week's meeting concern's Unesco's science and technology sector only in uncontroversial ways — the executive board is expected to take on the nod the secretariat's proposals for the invitation lists to this November's meeting on information technology and that planned for next year on problems affecting Latin America and the Caribbean. Moreover, science and technology are relatively well protected in the secretariat's proposals for trimming $10 million from the two-year budget for 1984–85. Indeed, the grant to the International Council of Scientific Unions has actually been increased.

Fireworks, if there are any, will rather attend the general items on next week's agenda, especially that requiring a first response to the British letter from Mr Timothy Raison, Minister of State at the Overseas Development Administration, sent to the director-general of Unesco in March. That letter asked that Unesco should reorder its priorities and improve the management of its affairs. At a later meeting in London, the director-general was told that continued British membership "could not be justified" unless there were signs of change at Unesco.

By all accounts, few expect that there will be much that is tangible to report from this first meeting of the executive board since the letter was sent, although the British will at least be looking for some mechanism by which their proposals can be studied seriously. But the responses of both the Unesco secretariat and the delegates of other member states are likely also to influence the spirit in which the British Government carries out its promised — or threatened — review of the benefits of membership.

Mr Ray Beverton, who succeeded Sir John Kendrew on 1 April as chairman of the science and technology subcommittee of the British National Committee on Unesco, said earlier this week that his group had not yet begun work in earnest on the task, but that a meeting had been arranged for May. □

Animal welfare

UK compromise and coercion

THE British Toxicology Society has thrown its professional weight behind the campaign by British animal welfare groups to end the LD_{50} test of acute toxicity. A special report by a working group of the society concludes that accurately determined LD_{50} values are rarely justified, and proposes an alternative test which it considers more humane while still providing essential safety data for product labelling and classification.

The LD_{50} test has long been a main target of animal welfare campaigners. New guidelines published in 1981 by the Organization for Economic Cooperation and Development (OECD) lowered the number of animals needed for the test, which establishes the quantity of a substance needed to kill 50 per cent of a group of test animals. Even with the new guidelines, however, 30 animals would typically be used for each LD_{50} determination.

The alternative proposed by the British Toxicology Society classifies substances into broad bands of toxicity based on their observed effects on animals at pre-set dosages. If survival at one level is more than 90 per cent, with no evident sign of toxicity, dosage is increased by a factor of 10; if it is less than 90 per cent, dosage is decreased by the same factor. This procedure continues until the pre-set level is found that causes evident toxicity but allows more than 90 per cent survival, which specifies the classification. With 10 animals per group and 3 classes of toxicity (as in the current EEC chemical regulations), on average between 10 and 20 animals would be used.

The Home Office in London is working on new proposals for animal welfare legislation, and is keenly aware of public pressure to reduce the number of animals used in routine testing. Mr David Mellor, Under-Secretary of State at the Home Office, is known to be sympathetic to the view that the continued widespread use of LD_{50} should not be necessary. The Toxicology Society hopes its acute toxicity test procedure will gain peer acceptance and become internationally recognized.

The claimed advantages, apart from compatibility with existing European systems, include the fact that (unlike LD_{50}) signs of toxicity are included in the assessment, while severely affected animals can be humanely killed without affecting the outcome of the study. The new test is also likely to be less variable between laboratories than LD_{50}. The long-term aim of the society is to force a European or a UK initiative in OECD aimed at establishing new guidelines. An existing EEC directive on dangerous substances that seems to imply use of the LD_{50} test would probably need amending.

Meanwhile, the Home Office is still undecided on how to modify the controversial "pain clause" in the draft proposals on animal experiments that it published last year. It is being pressed by the British Veterinary Association and others to extend the existing ban on experiments that cause severe and enduring pain to those causing severe pain or distress. The association, together with the Fund for the Replacement of Animals in Medical Experiments (FRAME), is also pressing for a linkage between the amount of pain or distress that may be allowed in an experiment and the potential benefits. Home Office officials are now thought ready to accept the principle of such a linkage.

Civil disobedience and violent protest against animal experiments are likely to be stepped up over the coming months in Britain. A coalition of hardline antivivisection organizations linked under the banner of "Mobilisation for Laboratory Animals" is planning a week of protests that will culminate in a national march on 12 May. The demands include a ban on the LD_{50} test and the Draize eye test, as well as cosmetics testing and all behavioural, psychological and military experiments. Last weekend, a security guard was injured when protesters broke into testing laboratories owned by Imperial Chemical Industries Ltd. Some parties to the "mobilisation" coalition condone, if not actually organize, protests that entail physical violence, and more violent incidents seem likely. Later in the year, according to a spokesman, a vigil will be held outside every animal laboratory in Britain.

Israeli–Egyptian relations

Cooperation in the doldrums

Rehovot

A LEADING Israeli physicist recently gave an "unofficial lecture" at a major Egyptian university. For political reasons, there was no advance notice of the lecture, organized by an Egyptian colleague whom the Israeli had met at a US conference. Word got around, however, and by the time the Israeli began to speak, the lecture room was crowded with young Egyptian researchers, most of whom stayed behind afterwards to discuss physics and to express the hope that full above-board links between Israeli and Egyptian scientists would soon be possible.

Although Israel and Egypt have been at peace for five years, there is at present only one place where scientists and scholars from the two nations can meet officially, the Israeli Academic Centre in Cairo headed by Professor Shimon Shamir of Tel Aviv University. The centre, sponsored principally by the Israel Academy of Sciences and Humanities, functions like the cultural centres of other nations, serving Israeli academics in Egypt for scholarly research, presenting lectures by these academics and giving Egyptian scholars access to Israeli research papers and books.

Such activities would be quite straightforward were it not for the fact that many in Egypt now regard all contact with Israel, no matter how innocent, as suspect.

Since the centre opened in May 1982, most of the lectures given there have been devoted to subjects of clear mutual interest. For example, Professor Sasson Somekh, an Israeli expert on Arabic literature and language, dwelt upon the fact that Hebrew and Arabic originate from the same linguistic family — and then dealt with problems of modernization in the same spirit. Similarly, Israeli musicologist Amnon Shiloah examined the influence of Arab music on Jewish music while Hebrew University Professor Hava Lazarus-Yafeh discussed the relationship between Halkha (Jewish religious law) and Sharia (Moslem religious law).

Sometimes, Israeli lecturers have reported on research carried out in Egypt itself. Dr George Kanazi, a senior lecturer in Arabic literature at Haifa University, told his Cairo audience about mediaeval Arabic manuscripts on the art of wine-drinking. Kanazi, himself a Christian Arab born in Nazareth, pointed out that even after the advent of Islam, which prohibits intoxicating beverages, laxity in the interpretation of Islamic law had made wine-drinking "a luxury that was sought and enjoyed".

Many of the Israeli researchers visiting the academic centre are interested in Islam and many of the Egyptians are similarly interested in Judaism.

Egyptian doctoral candidates have received information, for example, on "Elijah the prophet in Jewish and Moslem folklore" and "the author Aharon Megged as a representative of Israel's 1948 generation". Other PhD candidates have sought and obtained material for studies comparing Egyptian and Israeli approaches to education, social welfare and architecture.

The reactions of Israelis to these interactions, and to Egypt generally, are variable. Shamir says that "Israelis who come to Egypt looking for fanaticism, political rigidity and uncompromising hostility towards their country find these things; those who come looking for open-minded attitudes, warmth and a desire for peace find them also."

Shamir regrets that it is impossible to reach agreement just now for scientific cooperation between Israeli and Egyptian research centres but welcomes "the beginnings of a cultural interchange" at this centre.

Nechemia Meyers

Amersham International

Academic symbiosis flourishes

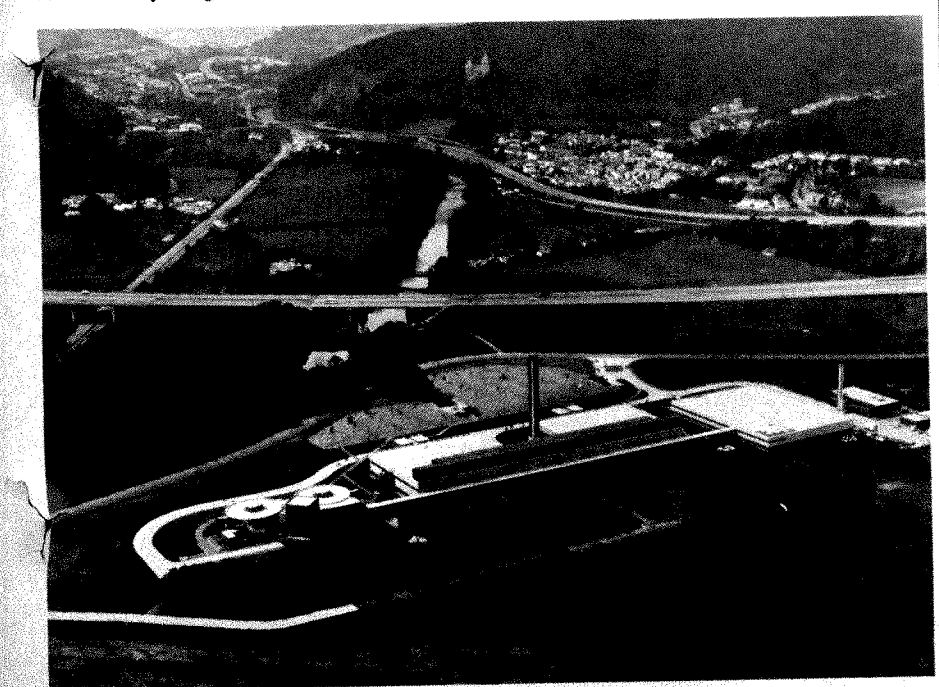
To sponsor a fellowship at the University of Cambridge, in a department (biochemistry) run by a knight (Sir Hans Kornberg) who is also master of a Cambridge college (Christ's), as Amersham International is about to do, may seem slightly odd for a company that thinks of itself as an adventurous creature newly emerged from the confining chrysalis of public ownership. But the Amersham Fellowship is a recognition by the company of the extent to which its growth, diversification and profit depend upon the progress (and demands) of academic research.

Dr J.C. Maynard, chief executive of the research products division — one of three into which the company is now organized — estimates that he has about 120 collaborations with academics, including sponsorship of several projects. That is largely why the company was able to market 130 new research products last year, many of them the result of an opportunist approach and many of them unrecognizable as products of what was, until 1981, the Radiochemical Centre.

The change of name followed a change of managing director and preceded the sale in 1982 of shares in the company by the British Government. (That move is reckoned to have cost the taxpayer dearly because of a gross underestimate of investor demand for the shares, which more than doubled in price after the sale.)

One striking change of business strategy has been that Amersham is taking a leaf out of the British dairy business's book. Just as the system of daily delivery of milk to British households is now being exploited to offer anything from meat to bread, so Amersham has decided to exploit its system for the speedy delivery of labile radiochemicals to market other products. The main thrust has been in the direction of molecular biologists. Since they all take deliveries of radiochemicals, why not offer them restriction enzymes as well?

Amersham seems to have made a considerable success out of just that, obtaining the enzymes from the Japanese market leader, Takara Shuzo. Perhaps five per cent of the sales of research products, which accounted for about a third of the company's £78 million turnover in 1983, is accounted for by restriction enzymes. But, as marketing manager Dr Brian Ellis is quick to say, Amersham faces much more competition in the sale of enzymes than in radiochemicals. Like all enzyme companies, Amersham would dearly like to have some unique enzymes on its list and would also like to offer reverse transcriptase, an essential enzyme for almost all molecular biolgists.



Other burgeoning sales to molecular biologists come from reagents for the cloning, packaging and sequencing of DNA. Most of the reagents are not radioactive, many are offered in convenience kits. (There is even an anti-DNA kit, not so much an anti-research product as an aid to diagnosing the presence of antibodies to DNA in clinical blood samples.) Like many other companies, Amersham is also looking hard at the possibility of supplying non-radioactive alternatives to the current DNA probes but so far none is of sufficient sensitivity, says product manager Mahomed Jassat.

More in the traditional line of the company, but typifying its new approach, are radioisotopically labelled ligands for receptors on the surfaces of cells. "It's a flavour of the month business", says Ellis. The trick is to be very quick off the mark to produce new ligands after their discovery and before they are displaced by something better. It can take Amersham as little as three months to launch a new product. Some may sell for not much longer than that, and to the tune of only a few thousand pounds, but still be worthwhile.

Financially as well as physically, Amersham has been growing since it went public in 1982. The half-year figures for 1983 show sales and profits more than 20 per cent up on 1982. More than 80 per cent of sales are overseas, business is booming in Japan and the company feels it is gaining on its arch-rival, New England Nuclear, in the United States. In physical terms, the staff of Amersham now tops 2,000, the administrative staff is to move into offices being built close to the Amersham site and research staff will soon start to occupy what was the Pollards Wood Research Station of the Institute of Cancer Research, a few miles away.

That move is part of the two-year plan under which expenditure on research and development will increase from 8 per cent of sales to 10 per cent. As long as price resistance does not hit sales, Amersham will soon be in better shape than ever to take advantage of the many ideas that seem to be flowing from its contacts in academic life.

Peter Newmark

Signs of growth — Amersham's new facilities at Cardiff.

Taxing problems

MANY readers of *Nature* who have been alarmed to learn that foreign visitors earning income in the United Kingdom will in future be taxed like residents (*Nature* 26 April, p.762) have nothing to fear. The proposed changes in tax relief for non-domiciled employees working in the United Kingdom for non-resident employers, now in committee stage in the British Parliament, do not affect those working as teachers or professors at a recognized educational establishment, or those who are undertaking research that is for the benefit of the general public.

People in these categories will continue to enjoy total freedom from taxation in the United Kingdom, provided that the visit is for less than two years. Under double taxation relief agreements, this exemption is reciprocal and so would apply also to British academics visiting foreign countries to teach or carry out research.

Those unfortunates who are not teaching, or whose research is for the benefit of private individuals or companies, will not in future benefit from the special reduction for short-term visitors to the United Kingdom, currently calculated at a deduction of 50 per cent on earnings. From 1987 the relief will be reduced to 25 per cent and from 1989 it will be withdrawn entirely. □

Labs worth visit

SIR — Your cheap sneer (*Nature* 15 March, p.24) that "many once adventurous laboratories have become places where ageing investigators brood on their pension rights" perhaps reflects the fact that your reporters are no longer visiting these laboratories. If they did, they would recognize the exciting and high calibre research which is being conducted against a background of continuing cuts in both staff and equipment. They might also recognize the high regard with which these laboratories are held by overseas scientists if we are to judge by the number of requests received from scientists in developed and developing nations alike to visit and work in these laboratories.

Nuclear abstracts

SIR — M. A. Bray (*Nature* **307**, 206; 1984) had expressed concern about the large number of abstracts appearing in databases. J. R. Metcalfe (*Nature* **308**, 222; 1984) questioned whether conference abstracts should even be included in databases.

For the nuclear physics bibliographic databases maintained at the US National Nuclear Data Center (NNDC), secondary references such as meeting or conference abstracts and dissertation abstracts are routinely coded. In the bibliography to neutron-induced reactions (CINDA system), all references to a given research work (either experimental or theoretical) are blocked together in the database. Abstracts are entered with a "no book flag" so that they never appear in the semi-annual cumulative publication, unless the abstract constitutes the only reference in that block. However, all entries can be obtained in a computer retrieval. The same was true for the charged particle induced reaction bibliography (CPBIB) system.

For the nuclear structure bibliography (Nuclear Structure References system) which is published thrice annually, there is no blocking. However, the secondary references appear in a section separate from the primary journal listings. In support of Metcalfe's arguments in favour of inclusion, the interval between an initial abstract and a published paper can be from one to five years. This time factor is significant (1) to alert a potential researcher that another group is already working on the same problem which could possibly avoid duplication and wasted research funds and (2) to direct a potential user to the researcher for more details on the work prior to publication.

They are not alone

SIR — Is the individual research scientist becoming an endangered species, as more and more disappear into the relative obscurity of "research teams"? An investigation of the pages of *Nature* suggests that this is indeed the case.

Since 1979, the number of "Letters to *Nature*" published has been in the region of 1,200 per year. However, throughout this period, there has been a gradual annual reduction in the number of single — and double — author papers coupled with an overall decrease in manuscripts with three named authors. This marked decline has been accompanied by a major increase in the number of multi-author papers.

A breakdown of the 1979 and 1982 quota of Letters to *Nature* clearly illustrates the change of distribution. During the four years, the decrease in letters with three authors or less was reflected by the steady rise in the average number of authors per letter, the 1982 figure standing at a mean of 3.17 authors per paper which represents a 14 per cent increase overall.

The observed shift towards multiple authorship in *Nature*, illustrated by the presence in 1980 of a 2½ page article with 27 named authors, poses the question: has scientific research become specialized to such an extent that individuals must now pool their expertise in order to successfully carry out a research project?

The most likely cause for the conspicuous movement away from single-authorship is, perhaps the "publish or perish" syndrome. Drastic funding cutbacks in the private and public sectors, worldwide recession and the threat of unemployment have all intensified the pressure on researchers to protect their positions. Being named on as many publications as possible, no matter how remote the connection with the original research work, is one way of proving one's competence.

Homer's *vino*

SIR — Will someone in the Mediterranean please confirm or refute Wright and Cattley's chemical hypothesis about Homer's "wine-dark sea" (*Nature* **303**, 568; 1983). I tried with French wine using Copenhagen water that is alkaline enough to turn red cabbage blue, but all I got was a tasteless red fluid. Perhaps "wine dark" refers to the lack of turbidity in wine. Coastal and inland waters are usually turbid whereas the clarity of deep Mediterranean waters off rocky shores could be compared to the clarity of wine. If so, "wine clear sea" would be a better translation and close to the Dutch/Afrikaans (?) *wijnkleurige zee* quoted by Macnamara (*Nature* **307**, 590; 1984).

The use of οινοπα ποντον as a fixed Homeric metaphor without necessary reference to colour has an analogue in modern English. What is the skin colour of most of the *white* men you have seen recently?

Only correct

SIR — Two errors are becoming commoner in scientific writings.

(1) The word "only" is being shifted forward, away from the word it modifies. Note the differences among the following: "Only I saw the white shark" (no-one else was on deck). "I only saw the white shark" (I didn't actually catch it). And "I saw only the white shark" (there were no grey ones around).

(2) Within the past few years the word "within" has been supplanting the simpler "in", usually without cause. Rats live within cages, particles sediment within a limited space, trees within a given area grow and die. In such contexts, what is wrong with using "in"?

Benefits of measuring time

Further data from the eccentric binary pulsar reaffirm the value of observations extended over time. The reality of gravitational waves is confirmed, the masses of the stars remain a puzzle.

THE old adage that if you must make measurements, you had better use a clock for then you will have time on your side, has been verified again. Almost exactly five years ago, Professor J.H. Taylor, the radioastronomer then at the University of Massachusetts at Amherst, described the first measurements of what is affectionately known as his pulsar (*Nature* **277**, 437; 1979) that were accurate enough to constitute a proof that gravitational radiation is real. In fact, the object that Taylor has been observing closely for the best part of a decade is not an isolated pulsar, but a binary system — a neutron star and a companion star of roughly equal mass.

The good luck is that the two objects are tightly bound — the orbital period is 7 hours 45 minutes — and that the orbit is also markedly elliptical. And the consequence of that is that the precession of the orbit resulting from non-Newtonian gravitational forces is rapid — more than 4 degrees a year, compared with a mere 0.43 seconds of arc a year for the precessing of the perihelion of the planet Mercury in its orbit about the Sun. Gravitational waves enter because the orbital period (not in this connection to be confused with the rotational period of the pulsar of 0.059 seconds) is decreasing, which implies that the system is losing energy in a way that can be explained only by gravitational radiation.

Taylor, now at Princeton University, has now, with J.M. Weisberg of the same laboratory, brought the story of the pulsar 1913 + 16 up to date (Weisberg and Taylor, *Phys. Rev. Lett.* **52**, 1348; 1984). Observations with the 300-m Arecibo dish in Puerto Rico have been accumulating for the whole of a decade. Altogether, there are more than 3,300 separate measurements, each consisting of the integration of the 5,000 or so pulsar wave forms received in a 5 minute interval. The authors say that their binary system is "uniquely suitable" for testing the prediction of general relativity that the members of a binary system should "gradually spiral together as the system loses energy in the form of gravitational radiation", but many of their readers will be more impressed by the astonishing precision with which the orbit of the binary system can now be described.

Inevitably, the orbital period is the most accurately determined of all the quantities involved. The standard error of the period, in round numbers 27,907 seconds, is a mere 20 microseconds, comparable with the standard error of a single measurement of the time of arrival of the individual pulses in one of the elementary observational periods of 5 minutes. But with a terrestrial atomic clock accurate to 1 microsecond, should it not have been possible to do even better after 10 years of observation? With more than 1,000 orbits every year, 10 years of observations should after all give a periodic time accurate to within the standard error of the clock divided by 10,000, say a nanosecond or so. And are not the rotational periods of many pulsars known to an accuracy of better than 1 picosecond?

The snag is that a system is much more complicated than an ordinary bare pulsar. With both kinds of objects, of course, it is necessary to correct the times at which pulses are expected to arrive for the physical motion of the Earth in its orbit around the Sun (which can make a difference of more than 2,000 seconds for an object in the plane of the ecliptic). For a binary system such as Taylor's, it is necessary to extract from what is essentially a sequence of time-marks all the characteristics of the pulsar orbit. One practical difficulty with Taylor's pulsar is that its signal is weak, though reproducible, so that the usual trade-off between receiver bandwidth and time precision arises.

With the passage of five years, however, the precision with which quantities such as the eccentricity of the orbit (numerically, 0.617 and now known to 3 parts in a million) can be known has been improved by a factor of at least two. The most striking improvement has come in the estimate of the projection of the semi-major axis of the elliptical orbit on the line of sight (a factor of five), the rate at which the orbital period is decreasing (a factor of seven) and, most important, the rate of precession of the orbit (a factor of six). A decade from now, this distant orbit may be as well known as, say, the orbits of some of the satellites of other planets in the Solar System.

Conceivably, the precision of some of these quantities may be dramatically improved by a technique Dr A.G. Lyne of the Nuffield Radio Astronomy Laboratories of the University of Manchester at Jodrell Bank has been exploiting in the study of another binary system one of whose members is also a pulsar. By all accounts, it is possible to exploit the irregular pattern of ionization in the general direction of a pulsar which is part of a binary system to infer the position of the pulsar in its orbit from the scintillation of the pulsating radio signal. For practical purposes, the ionization pattern in the intervening space functions as a kind of scale against which the position of a pulsating star can be pinned down. No doubt Taylor will be anxious to see whether the space intervening between here and PSR1913 + 16 allows this to be done.

Even as things are, however, Weisberg and Taylor have a good deal to say. In 1982, Taylor and Weisberg (*Astrophys. J.* **253**, 908; 1982) were saying that the data accumulated by then ruled out all gravitational theories except general relativity and the Brans-Dicke theory. Now they say that only Einstein's theory will square with the observations.

Weisberg and Taylor also say that their data now reveal a delay in the signal from the pulsar in those parts of the orbit from which the line of sight passes through the gravitational field of the companion star. This is the phenomenon now frequently observed when the line of sight to a pulsar grazes the limb of the Sun. Weisberg and Taylor say that their data constitute the first observation of this effect outside the Solar System.

The other striking and newish development is that the masses of the two stars have now been pinned down much more precisely than has previously been possible. The essential difficulty is familiar — that the masses of celestial objects whose gravitational interactions are those of point masses cannot be derived from Newtonian mechanics. But for the binary pulsar, the relativistic corrections, the advance of the periastron for example, are necessarily the least certain. But these are precisely the properties of the system whose precision has been most strikingly improved in the past five years. And the outcome makes more remarkable what has seemed from the start a strange coincidence — the masses of the two stars are indistinguishable both from each other and from the Chandrasekhar limit for collapse to a neutron star. So is it just possible that each of the stars is a neutron star, but that only one of them is a pulsar? It may be possible to learn something about the nature of the companion star if the measurements become precise enough for mutual tides to show up, but on the face of things not even the passage of time will allow this intriguing question to be answered.

John Maddox

Acquired immune deficiency syndrome

Retroviruses linked with AIDS

from Robin Weiss

THE publication of four papers[1-4] in the 4 May issue of *Science* by R. C. Gallo and colleagues on a link between acquired immune deficiency syndrome (AIDS) and a retrovirus related to human T-cell leukaemia virus (HTLV) was preceded by much comment which has generated considerable confusion. The main causes of this sorry state of affairs are the intense interest in, and fear of, AIDS and the decision that the US Secretary of State for Health should herself announce 'the identification of the cause of AIDS' and hence the 'means of prevention'. Moreover, rivalry and lack of cooperation between different US governmental agencies — the Center for Disease Control, the National Institute of Allergy and Infectious Diseases and the National Cancer Institute (NCI) — led to uncoordinated press statements. These have exacerbated the already contentious matter of deciding precedence between L. Montagnier's group at the Institut Pasteur in France, which published first[5,6] but with skimpy data, and Gallo's group at NCI, which delayed submission until a thorough characterization of their virus and repeated isolations from different patients had been accomplished. Furthermore, the two groups are using three different names for what I believe will turn out to be the same virus.

Why look for a virus?

There no longer seems to be any doubt that AIDS is caused by an infectious agent. The view that it might instead result from repeated exposure to different human antigens, while plausible for homosexuals with multiple sexual partners and for haemophiliacs receiving factor VIII pooled from thousands of blood donors, cannot apply to AIDS developing after a single blood transfusion or in infants of affected mothers. What kind of infectious agent, then, might give rise to this disease? Again, the discovery of the transmission of AIDS by blood or by semi-purified blood products helped narrow the field because it is unlikely that a fungus or a bacterium (perhaps secreting an immunosuppressive toxin comparable to cyclosporin A) would be transmitted by such routes. In any case, no sooner had AIDS been categorized as a new, epidemic and usually fatal syndrome in 1981, than the search for its causative agent was directed mainly towards viruses.

AIDS patients, and those with extended lymphadenopathy syndrome (ELAS) which may be either a milder form or early phase of AIDS, are infected with many viruses. Cytomegalovirus, Epstein-Barr virus and hepatitis B virus are examples of ubiquitous persistent infections in the population at risk as well as many other individuals. They may appear in more virulent form in AIDS and ELAS patients but that is probably a result rather than a cause of the disease. In turn, they may play a part in exacerbating immune deficiency once it sets in, but these well known widespread viruses did not seem likely to be the initiating agent of AIDS. Instead the pointers were towards a new virus, or a new satellite agent which might increase the pathogenicity of a common virus, just as the delta agent causes hepatitis B to be more severe.

Montagnier's viruses (LAV and IDAV)

Last May, Montagnier and colleagues reported the transient production of cell-free reverse transcriptase activity and virus particles when leukocytes from an ELAS patient were co-cultivated with fresh T cells from normal subjects[5]. The virus showed no cross-reaction with the core antigens of HTLV-1, the virus that is frequently associated with human T-cell leukaemia, though there was slight cross-reaction with antigens on the membranes of HTLV-1-infected cells. Montagnier named the virus lymphadenopathy virus one (LAV-1). Scepticism of the French group's observations grew because other laboratories had difficulty in confirming them and because of a widely held opinion among electron microscopists that the particles depicted in the paper resembled an arenavirus more than a retrovirus.

At the Cold Spring Harbor Meeting on HTLVs last September, Montagnier presented further data, including electron micrographs of particles that resembled D-type retroviruses with truncated (cylindrical) cores and long stalks where budding of the virus from the plasma membrane of infected cells was incomplete[7]. The major core antigen, p25, of LAV-1 was found to be antigenically related to equine infectious anaemia virus (EIAV), a little-studied retrovirus that causes haemolytic anaemia and fever in horses. In its ultrastructure, EIAV is similar to LAV-1 as seen in the more recent electron micrographs[7,8]. At Cold Spring Harbor, Montagnier also described further isolates of retroviruses from two AIDS patients[7], one of them a haemophiliac. The virus from the haemophiliac and a virus isolated from his brother, who is also a haemophiliac but does not have AIDS, have recently been described in *Lancet* [6] and have been named immune deficiency associated viruses (IDAVs). IDAV is indistinguishable from LAV.

These viruses are promising candidates as aetiological agents of AIDS and ELAS because 60–75 per cent of AIDS patients have serum antibodies that react with the p25 antigen of LAV-1, and because they are cytotoxic *in vitro* to the OKT4$^+$ subgroup of T cells which contains the majority of helper T cells. To date, LAV-1, IDAV-1 and IDAV-2 have not been thoroughly characterized biochemically, and permanent cell lines producing the viruses are not yet available, although nearly a year has passed since the first report of LAV appeared in print[5].

Gallo's virus (HTLV-3)

The virus now described by Gallo *et al.* has been designated HTLV-3 because it is considered to be a new member of the HTLV family (now called lymphotropic, instead of leukaemia, viruses). Some 50 HTLV-3 isolates have been obtained from different AIDS and ELAS patients with the ingenious use of a T-cell leukaemia line (HT) that is highly permissive to HTLV-3 replication[1]. The infection of HT by HTLV-3 is easily detected by the formation of syncytia similar to those we described for HTLV-1 and HTLV-2 (ref. 9). The continuous production of high titres of HTLV-3 in HT allowed Gallo's group to characterize the viral proteins and prepare antibodies to them. Schüpback *et al.*[3] report a cross-reaction of HTLV-3 p24 with other HTLV strains, particularly HTLV-2. Genome analysis, yet to be published[10], indicates that HTLV-3 is significantly related to HTLV-1 and HTLV-2.

More than 80 per cent of ELAS and AIDS patients have serum antibodies that are related to specific HTLV-3 antigens, especially the envelope glycoprotein, gp41. A relatively high proportion of a small sample of homosexuals and drug addicts without AIDS also have HTLV-3 antibodies.

Are HTLV-3 and LAV/IDAV the same virus?

The NCI group place their AIDS virus firmly in the HTLV family whereas the French group have emphasized that their virus has antigens that cross-react with EIAV and that it lacks relationship to HTLV-1. Nonetheless, in my view the similarities between HTLV-3 and LAV are more remarkable than the discrepancies. Disregarding the original electron micrographs of Barré-Sinoussi *et al.*[5], the ultrastructure of both viruses is very similar (compare Fig. 2 of Vilmer *et al.*[6] with Fig. 1 of Gallo *et al.*[2]). While HTLV-1 and HTLV-2 endow OKT4$^+$ cells with indefinite growth potential, neither HTLV-3 nor LAV has this capacity for 'immortalization'. Both HTLV-3 and LAV can be passaged as free virus, whereas HTLV-1 is much less stable and unlikely to survive the process of factor VIII preparation — although we have reported cell-free transmission of HTLV-1 (ref. 11).

The apparent differences in immunological cross-reactions could be explained by the different tests and reagents used by

the two groups, particularly as HTLV-3 is more distant from HTLV-1 than HTLV-2 and most AIDS and ELAS patients lack antibodies recognizing p24 of HTLV-1. Given the relationship claimed between LAV and EIAV it will be interesting to ascertain whether the latter belongs to the HTLV family (which includes bovine leukosis virus). The relationship of HTLV-3 and LAV could be rapidly resolved by an exchange of reagents between the two laboratories.

A serological test devised in Essex's laboratory[12] (the 'HTLV-MA' assay) appears to correlate closely with AIDS and ELAS in homosexuals, haemophiliacs and other recipients of blood transfusions[12-14]. The HTLV-MA test is an immunofluorescence assay of the binding of serum to the surface of HTLV-1-infected cells, in particular to the gp61 envelope precursor of HTLV-1 that has been defined by Hattori *et al.*[15]. I have been frankly dubious about HTLV-MA as a specific test of HTLV-1 antibodies because of its lack of correlation with our more specific env antigen assays[9,16] and because faint fluorescence at 1 in 4 dilutions of serum were counted as positive. It now seems much more likely that the HTLV-MA weakly cross-reacts with HTLV-3 or LAV. No doubt Essex *et al.* will re-analyse their sera using a more appropriate antigen. Indeed, as mentioned earlier, a weak cross-reaction by live-cell immunofluorescence between sera of LAV-positive patients and HTLV-1-infected cells has been observed[5].

Immunodeficiency caused by other retroviruses

One of the reasons for suspecting that a retrovirus might be the cause of AIDS is that several animal viruses (including some strains of avian and feline leukaemia viruses) are known to cause various kinds of immunodeficiency, anaemia and aplasia. Indeed, it has not been lost on opportunistic retrovirologists that the US AIDS budget is a lucrative source of research funds. For years, the immunodeficiencies caused by some retroviruses were regarded as a nuisance because infected animals died of 'laboratory' infections before they could develop leukaemia. The focus of pathogenesis has curiously changed in recent months with an eruption of vintage viruses carrying new appellations such as FAIDS (feline AIDS) and SAIDS (simian AIDS).

The prototype D-type retrovirus, the Mason-Pfizer monkey virus (MPMV), was first isolated from a rhesus monkey in 1970 (ref. 17). Much effort was expended in attempts to demonstrate oncogenic properties of MPMV but as Fine and Schochetman's excellent 1978 review[18] relates, the only pathogenic effect of MPMV was runting and immunodeficiency. Recently, outbreaks of simian 'AIDS' in the New England and California regional primate centres have been closely associated with a new strain of D-type virus related to MPMV[19,20]; experimental inoculation of this virus into young monkeys induces the disease [20]. Simian AIDS differs from human AIDS in affecting a much wider spectrum of blood cells than OKT4$^+$ T cells; nonetheless the identification of a retrovirus with this disease is of considerable interest. The human AIDS viruses are not antigenically related to MPMV.

HTLV-1 in AIDS/ELAS patients

HTLV-1, until recently known as ATLV in Japan[21], is most closely associated with adult T-cell leukaemia–lymphoma[22], a malignancy of OKT4$^+$ T cells. This clearly influenced Gallo's search for a virus in AIDS patients as it seemed reasonable to surmise from a knowledge of animal retroviruses that the same virus that initiated clonal malignant transformation in one situation, or a variant, might destroy the same target cell population in another situation. Another hint came from the fact that opportunistic infections, as characterize AIDS, frequently accompany the appearance of HTLV-1-induced malignancy.

Last year, Gallo's laboratory reported the isolation of HTLV-1 and proviral DNA from homosexual AIDS and ELAS patients[23,24], and the same virus has been identified in Haitian infants with AIDS[25]. Using serological tests which do not cross-react with HTLV-3/LAV we have also found that about 5 per cent of ELAS patients in London have antibodies specific to HTLV-1 (ref. 26), a far higher incidence than in healthy homosexuals and random blood donors. The significance of HTLV-1 infection in subjects at risk of AIDS is not clear, but from its low prevalence it seems more likely to be a blood-borne infection reflecting the life style of the patients than an alternative aetiological agent of AIDS.

Prospects for controlling AIDS

If HTLV-3/LAV really is the cause of AIDS, and I find the evidence convincing, then several important developments should occur quickly. First, we need to know what proportion of patients at risk actually have evidence of infection. The preliminary report [4] that a substantial proportion of clinically normal homosexuals have HTLV-3 antibodies is worrying, if it is a forewarning of future illness; it is clear, however, that cofactors play an essential part in precipitating AIDS. Second, reliable ELISA screening tests for blood banks are urgently needed, and might have to be used as routinely as tests for hepatitis B virus. Third, there is the prospect of developing prophylactic immunization and perhaps intervention for infected individuals too. As Groopman pointed out in these columns last week[27], the economic and logistical impact of the identification of the cause of AIDS is formidable, and the seropositive individuals will face severe psychological and behavioural problems.

I am most grateful to R. C. Gallo and L. Montagnier for permission to utilize information in papers in press for this article. □

100 years ago

In a crowded house on Tuesday last the Convocation of the University of Oxford passed the much-debated statute allowing women to enter for "certain of the honour examinations of the University." The statute has been opposed on very different grounds. The old Conservative Oxford School (fast becoming extinct among the resident teachers) of course objected to any change in favour of the higher education of women; with them went a portion for the High Church party, who look with disfavour on any proposal tending to bring women into intellectual competition with men. Others, again, opposed the statute on the ground that it was unfair to men, who have to keep certain terms and pass certain examinations within a specified time if they wish to enter for an honour school, whereas the statute allows women to enter for honours without the same preliminary examinations, and without restrictions as to time and residence. Others again feared an influx of young ladies into Oxford, as likely to destroy the manliness of the undergraduates and spoil the natural modesty of the lady students. To these arguments the success which the present halls for ladies in Oxford have met with is the best answer. Their presence has not revolutionised the University; they have not been a stumbling-block to discipline nor a rock of offence to the Church. The women's examinations were on the same subjects, and the papers were set by the same men, as in the men's honour examinations before this statute passed. Now the same papers will serve for both, trouble will be saved, and the women who obtain honours will win a certificate universally recognised throughout the country. Ocean ecology

Fixation of CO_2 in dark midwater zones of the ocean

from Paul Tett

IF the ocean began as a rich organic soup, it has since become so poor that many organisms have difficulty in getting enough energy and organic matter for growth and reproduction. The evolution of photoautotrophy must have been a breakthrough, allowing the light-driven uptake of simple inorganic compounds of carbon, nitrogen and phosphorus to supply the entire food needs of many planktonic plants. The illuminated superficial waters of the sea (the 'euphotic zone') are thus commonly seen as the main region of primary production, particularly by phytoplankton, whereas the deeper waters are seen as a zone of consumption in which heterotrophic animals and bacteria meet their energy demands by the oxidation of organic carbon supplied from the euphotic zone. On page 54 of this issue of *Nature*, Karl and his colleagues present evidence to suggest that bacteria in the midwater between the two zones can intercept the organic particles falling from the euphotic zone and, despite the absence of light, use the energy trapped in them to convert additional carbon dioxide into organic carbon (chemolithotrophy)[1].

As the earliest living organisms, prokaryotes probably exploited both inorganic and organic sources of energy and carbon until the development of the eukaryotes with their greatly improved efficiency of photosynthesis at high oxygen concentrations. That probably caused many of the remaining bacterial prokaryotes to specialize in heterotrophy — hence the traditional view of modern oceanic prokaryotes as degraders, consuming organic material originally produced by eukaryotic phytoplankton. Recent investigations of the smallest phytoplankton have, however, shown the importance of the prokaryotic cyanobacteria (once called 'blue-green algae') in oceanic primary production[2,3]. And incorporation of carbon dioxide by thermophilic bacteria, using energy obtained by oxidizing locally enriched sulphide, iron or manganese, has been suggested as a source of primary production in food chains found near volcanic vents in deep water[4,5]. From careful analyses of sedimenting material collected by free-floating traps at depths between 50 and 2,000 m in the eastern tropical Pacific Ocean south-west of Mexico, Karl *et al.* now add the suggestion that energy initially harnessed photoautotrophically by euphotic-zone phytoplankton for the incorporation of inorganic nitrogen (as well as carbon) can subsequently be chemolithotrophically used by midwater microorganisms to fix additional carbon dioxide[1].

The chemolithotrophic microorganisms involved are probably denitrifying bacteria using the ammonium produced by the action of heterotrophs on the organic material sinking down from the euphotic zone. By oxidizing this NH_4^+ to NO_2^- the bacteria can obtain sufficient energy to take up carbon and reduce it to organic compounds. This chemolithotrophic use of nitrification to provide energy for carbon incorporation is less efficient than photosynthesis which, under optimal conditions, yields 0.08 moles of organic carbon for each einstein of light. Karl *et al.* cite yields of 0.03–0.06 moles of carbon fixed for each mole of ammonium–nitrogen oxidized, and estimate that potential chemolithotrophic production by microbes in their study region requires a maximum ammonium flux of about 0.8 mmol per m^2 per day. This flux, if completely supplied from photoautotrophically produced material with a carbon to nitrogen ratio of 7:1, requires an annual photosynthetic production of about 30 g carbon per m^2, close to lower estimates of tropical oceanic primary production. The greatest estimated chemolithotrophic production, about 0.4 mg carbon per m^2 per day, is equivalent to an annual average of 146 mg carbon per m^2, clearly only a small proportion of phytoplankton production. The suggestion by Karl *et al.* that "the flux of energy out of the euphotic zone may greatly exceed that nominally contained in particulate organic detritus" thus overemphasizes the importance of midwater chemolithotrophy, but these microbial processes may well influence the organization of midwater food webs.

Chemosynthesis has, of course, been known for many years and may, in unusual regions, such as the Black Sea, rival photosynthetic production[6]. Oceanic chemolithotrophs have ample supplies of their carbon source; their problem is to find at near-normal oxygen concentrations a sufficient concentration of energy source. In the Black Sea, chemosynthesis makes use of the high concentration of reduced material accumulated in the deoxygenated waters. The thermophilic bacteria of the deep-sea volcanic vents probably exploit local enrichments of reduced compounds[4,5]. Perhaps the major novel contribution of Karl and co-workers is to document precisely a mechanism whereby chemolithotrophs can, through oxidizing ammonium associated with sinking particles, obtain sufficient energy for growth in the oligotrophic ocean.

Igneous petrology

Turbulence in petrology — the behaviour of komatiites

from E.G. Nisbet

CONSIDER the business of stamp-collecting: an elegant and harmless occupation of considerable economic benefit to countless post-offices, a source of endless diversion and speculation to the philatelist. Consider now the effect on that peaceful hobby of the discovery, somewhere to the east of Laputa, of a whole new continent filled with hitherto unknown national post-offices. Imagine the excitement and confusion of innumerable collectors scurrying in for examples. Eventually order is restored, what purports to be a comprehensive philatelic history is written and the hobby settles down to its normal delightful ways — until someone points out that some of the new stamps, though not exactly forgeries, are subtle but highly misleading overprints. But it is not clear how to identify them. Is history to be rewritten? Confusion returns.

Igneous petrology may not quite be stamp-collecting but it, too, has its excitements, as when komatiites were discovered fifteen years ago. This sent many field workers scurrying to collect samples from which much has been learnt about the chemical properties of komatiites. Now Huppert *et al.*, on page 19 of this issue of *Nature*, cast doubt on some (but not all) of the current notions about the chemistry of komatiites from an examination of the physical properties of komatiite liquids[1]. More reassuringly, they also provide some explanation of how komatiite lava flows can produce extraordinary large plate-like ('spinifex') crystals of olivine, thereby resolving a conflict between experimental results and cooling models.

When discovered, komatiites were a

wholly new class of extrusive igneous rock, rich in MgO and generally of Archaean age (older than 2.5×10^9 yr). Apart from providing some of the best clues to the composition, temperature and workings of the mantle of the early Earth, they are also of considerable economic value for their large nickel sulphide deposits. Komatiite lavas must have been very hot (1,350–1,650°C) and have had very low viscosity (0.05–1 Pas). Moreover, moving bodies of komatiitic lava (such as magmas in conduits or flows) must have had high Reynolds numbers and thus generally have been turbulent and capable of eroding walls or floors to conduits[2]. From their detailed study, Huppert *et al.* show that komatiite lavas were typically turbulent, were accompanied by vigorous forced convection and that even for the narrowest fissures (0.3 m) their Reynolds number was probably far above the critical value for the onset of turbulence. Flow rates must have been very high: a 3-m-wide fissure would have had rates considerably greater than the largest eruptions in historic time.

In turbulent flow, mixing maintains a uniform temperature, heat transfer is much greater than in a laminar flow and, thus, the ground below the flow will heat up rapidly. Huppert *et al.* show that erosion by melting of this underlying ground would be rapid and significant. Assimilation of the melted ground would introduce up to 10 per cent contamination into the lava. Contamination would be of minor geochemical importance if the lava flowed over a ground made up of fresh subaerial komatiite flows; but if it flowed over hydrothermally altered flows, or over other rock types, or if it had arrived through a conduit lined with older rocks, the contamination could be of major significance. Fortunately for those making thermal models of the Archaean Earth, the MgO content of the lava (from which temperature estimates are principally derived) is not likely to have been changed much by contamination but the trace-element content could have been very substantially altered. Thus, radiogenic isotopes could be assimilated from an older country rock, leading to artefacts in dating. That may be the explanation for some anomalously old Sm–Nd dating of komatiites[3]. How reliable, then, is information from the incompatible trace elements, such as Ti, which has been used to construct geochemical models[4] of the source mantle? Huppert *et al.* point out that contamination is likely to vary greatly from place to place within a flow so that any set of flows which displays non-systematic variation of trace elements with indices of olivine fractionation is likely to be contaminated. Contrarily, the very systematic variations from Belingwe samples[5] may represent a pristine record (at least for some elements).

Huppert *et al.* also speculate about nickel sulphide deposits. Green and Naldrett suggested that some Canadian and Western Australian deposits might have assimilated sulphur from nearby sulphide-rich banded ironstones[6]. Huppert *et al.* consider that lava may have digested such sediments by thermal erosion. Sulphur isotope studies may help determine the value of their hypothesis — which could be useful in selecting exploration targets. Finally, Huppert *et al.* consider spinifex textures — the long plates of olivine that hang down in sheaves from the top surfaces of some komatiite flows. Experimental cooling rates necessary to reproduce these textures are much higher than rates allowed by conductive cooling models but convective cooling in turbulent flows would explain the textures nicely and Huppert *et al.* have produced good analogues of spinifex textures in Na_2CO_3 solutions.

What then for us stamp collectors? Clearly we must re-examine our data on the age and chemistry of komatiites and think again about the minor-element make-up of the mantle. Perhaps the recognition that contamination took place will help in resolving controversies about the extent of variation in chemistry of mantle source regions. More likely it will add to our uncertainty and send komatiitophiles scurrying back cheerfully to their field areas and to isotope laboratories. □

Cell biology

A budding interest in the yeast cytoskeleton

from Jeremy Hyams

COMPARED with the avalanche of papers devoted to the genetics and molecular biology of the budding yeast, *Saccharomyces cerevisiae*, which has sometimes threatened to bury the pages of this and some other journals over the past few years, yeast cell biology has had a fairly thin time of it. The trouble is that yeast cells are just not designed for the job — they are small, their cytoplasm is dense and, to make matters worse, they are surrounded by a tough cell wall. Hence the curious situation that, whilst yeast actin has been purified and its gene cloned and sequenced[1], absolutely nothing has been known about its distribution or function during the budding cycle. Tubulin is somewhat better characterized, particularly in terms of the number and arrangement of spindle microtubules during cell division[2–4], but the role, and even the existence, of cytoplasmic microtubules has been far from certain. A recent pair of papers in *Journal of Cell Biology*[5,6] therefore marks a major step forwards in yeast cytology.

Schematic representation of the changes in actin and tubulin distribution in budding yeast during the cell cycle (a–g). Microtubules appear as straight lines growing from the spindle pole body which is embedded in the persistent nuclear envelope. Actin is shown either as black dots or as fine fibres. From ref.5.

What made this work possible was the isolation of monoclonal antibodies to yeast tubulin[7]. Anti-tubulin antibodies have been valuable tools for cell biologists for several years but conventional anti-tubulin antibodies raised against mammalian proteins do not cross-react with the microtubules of more primitive eukaryotes. On the other hand, the monoclonal antibodies to yeast tubulin appear to be universally cross-reactive. Using them and immunofluorescence microscopy, Kilmartin, Adams and Pringle have not only demonstrated the distribution of actin and tubulin during the yeast cell cycle in stunning detail but have also gone a long way to solving some of the old puzzles about the role of these proteins during budding[5,6].

Applied to the parent organism, the yeast anti-tubulin monoclonals generate intense staining both of the mitotic spindle and of extensive bundles of cytoplasmic microtubules (see the figure). In cells which have not yet formed a bud, cytoplasmic microtubules extend from the nucleus to the site from which the bud will emerge. Double staining with anti-actin and

fluorochrome-labelled phallotoxins, which bind specifically to F-actin, shows this region of the cytoplasm to be occupied by a ring of brightly staining actin dots. Simultaneous staining with Calcofluor reveals that the actin dots directly underly the ring of chitin which is laid down in the otherwise chitin-free cell wall and which defines the budding site.

As the bud emerges and enlarges the actin dots are displaced towards the bud tip at the same time as fine fibres of actin extend through both the bud and the mother cell. During this reorganization the spindle forms and elongates. Significantly, in view of the current speculation regarding the role of actin in chromosome movement, no actin is detected within the nucleus at any stage of the budding cycle of yeast. When the bud has reached its maximum dimensions the actin dots disperse through the cytoplasm but then concentrate in the neck region at the time of cytokinesis.

The changes in the distribution of actin are consistent with the suggestion that actin has a role in the localized desposition of cell-wall materials, first in the chitin ring and later at the tip of the bud. A similar pattern of staining in another fungus, *Uromyces phaseoli*, led to the suggestion that the dots of actin were microvesicles coated with filaments having the same dimensions as F-actin ('filasomes')[8]. In *S. cerevisiae*, cytoplasmic microtubles may direct similar vesicles, containing cell-wall precursors, to their sites of deposition[2] or may simply serve to orient correctly the spindle for its later extension into the bud.

The introduction of effective immunofluorescence procedures to *S. cerevisiae* adds the yeasts to the list of organisms in which fundamental cell-biological problems can now be studied. Remembering the sophisticated genetics that has already been developed for yeasts, the potential of these simple organisms seems to be limitless. □

Cosmology

Fluctuations in microwave background radiation

from M.S. Longair

NEARLY twenty years after the discovery of the microwave background radiation by Penzias and Wilson, all but the most sceptical cosmologists are convinced that the hot big-bang model provides the most promising framework within which to study the more profound problems of cosmology. It has long been recognized that directional fluctuations (ΔI) in the intensity (I) of the microwave background radiation should be a powerful way of investigating a wide range of properties of the hot big-bang model. The detection of such fluctuations has, however, proved to be extremely difficult and it is only with the paper of Birkinshaw, Gull and Hardeback on page 34 of this issue that it is possible to say with confidence that at least one type of small-scale fluctuation has been observed.

The only anisotropic signal unambiguously detected so far at a level of about $\Delta I/I \sim 10^{-3}$ is associated with the motion of the Earth relative to the frame of reference in which the background is isotropic. Otherwise there are only upper limits to the intensity fluctuations, the most sensitive at a level of about $\Delta I/I \sim 10^{-4}$. The problem is that, at this level of sensitivity, very small instrumental effects can introduce spurious fluctuations while, in addition, the atmosphere introduces fluctuations due to astronomical 'seeing' in the radio waveband.

Birkinshaw *et al.* have searched for the small dips or decrements in the microwave background radiation first predicted by Sunyaev and Zel'dovich in 1968 on the grounds that the spectrum of the microwave background could be distorted by quantities of hot gas along the line of sight. If the gas were very much hotter than the black-body radiation, the hot electrons would heat the radiation by Compton scattering and, in a simple approximation, the whole microwave background spectrum would be shifted to a slightly higher frequency while the total number of photons will be unchanged. Thus, if the microwave background radiation traverses a region of hot gas on its way to the observer, there will be a decrease in the intensity in the long-wavelength (Rayleigh–Jeans) region of the Planck spectrum and an increase in the high-frequency (Wien) region.

Since X-ray observations with the Uhuru, Ariel V and Einstein satellite observatories have shown that there are vast quantities of hot gas at temperatures of 10^7–10^8 K in the direction of rich clusters of galaxies, Birkinshaw *et al.* turned the 40-m telescope of the Owens Valley Radio Observatory, California, in those directions in their search for intensity fluctuations. As a result, after years of marginal detections and several false starts, fluctuations at a high level of significance have been observed in the direction of three rich clusters of galaxies. The relative intensities of these fluctuations range from about 5×10^{-4} in the case of cluster 0016+16 to about 2×10^{-4} in the case of the Abell clusters 665 and 2218. It is particularly impressive that these values are all claimed at or above the 7σ confidence level — a striking measure of the sensitivity of the observations.

Astrophysically, this result is important because the fluctuations provide information about the hot gas which has modulated the microwave background in some particular direction in the sky. Indeed, the magnitude of the decrement is determined solely by the optical depth for Compton scattering by the hot gas, which is proportional to the electron density N_e, the electron temperature T_e and the dimension of the cloud in the line-of-sight. Complementary information about the hot gas can be found from X-ray observations of the clusters. The temperature can be obtained from the shape of the spectrum, which for energetic X rays is roughly proportional to $\exp(-h\nu/kT_e)$ while the total intensity of X-ray emission is proportional to N_e^2, to $T_e^{-1/2}$ and to the volume of the cloud.

Thus, if adequate spatial resolution is available at radio and X-ray wavelengths and the distribution of gas in the cluster is reasonably well behaved, the physical conditions are overdetermined so that the physical size of the gas cloud in a cluster can also be found. That, in turn, opens up the exciting prospect of a new route to the determination of Hubble's constant since we now know the physical size of a 'measuring rod' at a known redshift.

But this achievement is only the beginning of what Birkinshaw and his colleagues foresee as a new epoch in observational cosmology. The Sunyaev–Zel'dovich effect was probably the easiest of challenges; if sensitivity can be improved by an order of magnitude, a whole new range of phenomena will come within our observational grasp.

Among the most important goals is the discovery of fluctuations predicted to be associated with the initial collapse of protogalaxies and protoclusters. According to all acceptable theories of the origin of structure in the Universe, the growth of the fluctuations of ordinary matter from which galaxies and clusters have formed became possible only after matter and radiation were decoupled at a redshift of about 1,500, corresponding to an epoch of 10^6–10^7 years after the big bang. The requirement that galaxies and clusters should now exist results in lower limits to the material density fluctuations at that early epoch and thus, because of Compton scattering, to radiation anisotropies that should now be apparent as fluctuations in the microwave background in the range

$\Delta I/I \sim 10^{-4}$–10^{-5}. Observations of such fluctuations would provide strong support for the hypothesis that structures formed by collapse which began when matter and radiation decoupled. This is a rather general argument which remains valid even in recent scenarios of galaxy formation involving massive neutrinos and other weakly interacting particles that may contain most of the mass of the Universe.

Other sources are expected to produce fluctuations at about the same level. Thus the reheating of gas at a late epoch should induce fluctuations, while the passage of radiation through large collapsing structures can cause fluctuations by the gravitational redshifting produced in the process. Even the hot gas in rich clusters, now detected by Birkinshaw *et al.*, must yield fluctuations on a fine scale, and these may well limit the detectability of genuine primordial fluctuations.

Such an approach is, nevertheless, one of the few that can provide observational information about the epochs between about 10^7 and 2×10^9 years. Already, the Cambridge radioastronomers have developed proposals for achieving the extra factor of 10 in sensitivity needed to tackle these more ambitious programmes. It is hard to disagree with their view that the next decade will be a period when these exciting and fundamental observations become an integral part of astrophysical cosmology. □

Astronomy

Black holes, accretion discs and Seyfert galaxies

from C. Martin Gaskell

A LARGE consortium of European astronomers has recently published the third instalment of results of their ongoing programme monitoring the nearby Seyfert 1 galaxy NGC4151 with the International Ultraviolet Explorer satellite (IUE)[1]. Results have already been published from similar programmes monitoring other Seyferts (the lowest-luminosity quasars) but NGC4151, the first Seyfert to be discovered[2], has always received more ground- and space-based attention than any other. Considerable publicity before publication by the Royal Greenwich Observatory alleged that the 'mass of the black hole' in NGC4151 had been measured. Although this claim captured the imagination of the British press, the truth is that neither the IUE consortium nor anybody else has proved that there is a black hole in NGC4151 or any other quasar-like object. The mass estimated for the central object is in fact not new. An almost identical value was derived 25 years ago[3] and the basic method employed has already been used innumerable times over the last couple of decades. It is widely recognized that the method could be giving a wrong answer however. The IUE consortium claims to have made 'remarkable progress' in understanding the nuclear energy source of NGC4151, but, interesting as their observations are, unfortunately they neither prove nor disprove the current standard theory that quasars and similar objects are empowered by accretion of matter in a disc onto a massive black hole. Much of the interpretation of changes in the ultraviolet spectrum is probably wrong.

How do you estimate the mass of a quasar nucleus? The most direct way is to use Newton's law of gravity. Since one obviously cannot follow a single test particle around an orbit one has to use the integrated properties of the ensemble of cloudlets in the broad-line region and make certain assumptions. The most usual assumption is that the cloudlets are in bound orbits with an isotropic velocity distribution. To deduce the central mass one needs to know the average velocity and the average distance. The velocities of broad-line clouds have been well known since the pioneering work of Seyfert[4] in 1943. The Doppler widths of the broad lines imply velocities of several per cent of the speed of light. The sizes of broad-line regions were first calculated from photoionization considerations[3,5] but the subsequent discovery, in 1967, of variability of emission lines in Seyferts[6,7] permitted an independent estimate of the size of the broad-line regions from light-travel-time considerations[8]. The two methods are in satisfactory agreement. It is the latter method that Ulrich *et al.*[1] have used. Woltjer[3] estimated the central mass of NGC4151 to be 3×10^7 solar masses as long ago as 1959 and this sort of mass has been almost universally accepted by workers in the field ever since. Clearly the IUE observers have not made a new contribution here.

Are we confident that we know the mass of the central object fairly well? The answer is no. The problem with the standard newtonian calculation described above is that the assumption of bound orbits (or at least of cloud motions dominated by gravity) is not valid. There is abundant evidence for the outflow of gas from quasars and Seyferts in general (this has already been reviewed in a recent *News and Views*[9]) and in NGC4151 in particular[10]. If the cloud motions are dominated by radiation pressure (causing the outflow), rather than by gravity, the assumption of orbital motion is clearly invalid and the mass can easily have been overestimated or underestimated by an order of magnitude.

Why do we think that quasars contain massive black holes? All the arguments for the existence of massive black holes in active galactic nuclei are theoretical. If the mass of the central object is indeed 3×10^7 solar masses this does not automatically prove that it is a black hole rather than, say, a supermassive star or a spinar. Nonetheless, accretion of matter onto a massive black hole has long been considered the most likely source of energy in quasars[11]. If the accreting matter has any angular momentum at all it will collapse into a flattened configuration (an 'accretion disc'). Such discs are known to exist around many collapsed stellar objects (the dwarf novae, cataclysmic variables and so on) in our own Galaxy. The standard model of quasars is currently an accretion disc surrounding a massive black hole.

Although such discs are receiving considerable theoretical attention, the only observational hint that they exist around quasars is a slight curvature in the spectral energy distribution in the optical–ultraviolet region. Shields[12] has proposed that this could be due to thermal emission from an accretion disc superimposed on an underlying power-law non-thermal continuum. But this is by no means the only interpretation of the continuum energy distribution in quasar spectra. The interpretation is complicated by the presence of many weak blended Fe II lines[13] and uncertainties in the amount of reddening by dust in the quasars. The excess emission around 3,000 Å (the so-called '3,000 Å bump') is almost certainly Balmer continuum and blended Fe II line emission[14,15]. The remaining curvature in the ultraviolet–optical spectra of quasars can be understood in terms of standard synchrotron-self-Compton theory without invoking any additional thermal component at all[16]. If there is a thermal excess it does not have to be from an accretion disc — it could be from the

photosphere of a massive superstar[17] or from very-high-density broad-line-region gas close to the central object[18].

Observations of time variability of the continuum spectral shape of Seyferts and quasars are going to be important in understanding the origin of the continuum and the observations by Ulrich *et al.*[1] and others[19,20] have shown interesting changes in the ultraviolet continuum of NGC4151 and other Seyferts. IUE observations alone, however, just do not provide enough wavelength coverage and the changes reported are not, I believe, true changes in the continuum shape but rather changes in the relative intensity of the Fe II emission at 3,000 Å (that is, the 3,000 Å bump). This is probably the cause of the otherwise puzzling result of Ulrich *et al.*[1] that the C IV 1,549 Å emission-line variability is better correlated with the continuum emission at 2,500 Å than with the continuum further into the ultraviolet (that is, nearer to the relevant ionization edges), and other inconsistencies which they note. To measure the true continuum one needs to cover many octaves in frequency and it is to be strongly hoped that future IUE observations of NGC4151 (and other Seyferts) will be scheduled with simultaneous longer-wavelength optical and infrared observations (and for that matter X-ray observations as well).

Although our picture of NGC4151 and other active galactic nuclei is still very fuzzy and little has actually been proved, it must be said that everything is still consistent with such objects having at least one massive black hole in their centres (and some may have two[21]). Similarly there is no evidence so far that quasars do not have accretion discs powering them, but it would be nice to have proof that they do. □

Protein structure

Oxygen carriers of a third kind

from K.E. van Holde

HAEMOGLOBIN is not the only way to transport oxygen in a circulatory system. Some invertebrate phyla use altogether different proteins to serve this function. These include the haemerythrins, utilized by sipunculids, brachiopods and a few other invertebrates, and the haemocyanins, found in a wide variety of molluscs and arthropods. The structures of many haemoglobins, and even one haemerythrin[1], have been determined to high resolution by diffraction techniques, but until the paper of Gaykema *et al.*[2] on page 23, such information has been wholly lacking for the haemocyanins. This hiatus has seemed almost paradoxical, for the haemocyanins were the first proteins to be studied in detail by biophysical techniques, notably in some of the earliest ultracentrifuge studies of Svedberg and his collaborators[3].

The problem of how to bind oxygen in a way that is reversible receives a radically different solution in haemocyanins than it does in haemoglobins and haemerythrins. Rather than using iron as an oxygen ligand, haemocyanins employ pairs of antiferromagnetically coupled copper ions[4,5]. Such copper pairs are found in a number of other proteins, but for none of these is the detailed structure known. Thus the determination, to a resolution of 3.2 Å, of the structure of the haemocyanin of the spiny lobster, *Panulirus interruptus*, is of major importance.

The native molecule, which is one of the simpler haemocyanins, exists as a hexamer of two kinds of very similar subunits, each of molecular weight (MW) about 75,000. The entire hexameric structure has now been determined by Gaykema *et al.*[2], making it one of the largest proteins to be analysed by X-ray diffraction. The subunits are found to be arrayed with 32 symmetry; two trimers, related by 2-fold axes, are stacked face to face. Each subunit consists of three domains of approximately equal size. The second of these domains carries the copper pair. Each copper ion is bound by three residues, two of which are definitely histidines. The third ligand is probably also a histidine, but confirmation will require further sequencing.

The structure determined by Gaykema *et al.* seems to be that of deoxyhaemocyanin but studies of a subunit of *Limulus* oxyhaemocyanin are under way in the laboratory of W. Love, at Johns Hopkins University[6]. It will be of considerable interest to see how the oxy- and deoxy-structures compare, for haemocyanins are allosteric proteins, exhibiting both cooperativity in oxygen binding and heterotropic allostery, including a pronounced Bohr effect. So far, our only model for these functions has been haemoglobin (haemerythrin appears to be non-cooperative[7]); it is conceivable that similar effects will be found to be produced by quite dissimilar mechanisms in a protein as different as haemocyanin. This would represent an interesting example of convergent evolution of protein function.

The structure found for the haemocyanin seems wholly unrelated to that of haemerythrin or any haemoglobin, so haemocynanin must have a different ancestry. Is it shared with tyrosinases, ceruloplasmin and laccase, all proteins with a similar binuclear copper centre? Although the three-dimensional structures of these proteins are unknown, their amino acid sequences have certain motifs in common, suggesting similar modes of copper binding. In all three proteins there exist pairs of histidines separated by three amino acids, resembling those now identified among the copper ligands of haemocyanin. Confirmation of the hypothetical ancestry may be difficult, however, for the haemocyanins have presumably been evolving independently for something on the order of 500 million years. Indeed, a comparison of the complete sequence of a spider haemocyanin with *Neurospora* tyrosinase gave no evidence of homology[8].

Gaykema *et al.* point out a peculiar aspect of the *Panulirus* haemocyanin structure. Its carboxy-terminal domain contains a seven-stranded antiparallel β-barrel, remarkably similar in topology to the β-barrels in (Cu–Zn) superoxide dismutase and immunoglobulins[9]. Since the amino acid sequences are entirely different, they argue that this may simply be a very stable structure which has evolved independently in different proteins.

A final puzzle, which may be clarified by further structural studies, is the relationship between arthropod and molluscan haemocyanins. The oxygen-binding site of both types seems quite similar but their gross molecular architecture is entirely different. All known arthropod haemocyanins are built of 75,000-MW chains, arranged in hexamers, as in *Panulirus*. These hexamers are often combined to form even larger structures. On the other hand, the polypeptide chains of molluscan haemocyanins are much larger; units of MW about 400,000, containing eight globular domains and eight oxygen-binding sites, are commonly observed[4,5]. Gaykema *et al.* suggest that a molluscan domain of ~ 50,000 MW may correspond to two of the three 25,000-MW domains observed in the *Panulirus* structure, one carrying a binuclear copper site. Thus, it is conceivable that molluscan and arthropod haemocyanins arose via separate evolutionary events from some common copper-protein ancestor.

The new structural studies, combined with a number of sequence determinations now underway, promise to broaden our perspectives concerning the mechanisms that organisms have evolved to transport oxygen. □

Emplacement and cooling of komatiite lavas

Herbert E. Huppert*, R. Stephen J. Sparks†, J. Stewart Turner‡ & Nicholas T. Arndt§

* Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, UK
† Department of Earth Sciences, University of Cambridge, Cambridge CB2 3EQ, UK
‡ Research School of Earth Sciences, Australian National University, Canberra, A.C.T. 2601, Australia
§ Max-Planck-Institut fur Chemie, Saarstrasse 23, Postfach 3060, D-6500 Mainz, FRG

We propose that komatiite lavas were emplaced as turbulent flows, accompanied by vigorous forced convection with cooling rates often in excess of hundreds of °C h^{-1}. They melted and assimilated up to 10% of the ground over which they flowed, forming deep channels. Nickel sulphide mineralization may have resulted from incorporation of sulphur-rich sediment. After emplacement, high cooling rates persisted, resulting in spinifex textures due to compositional convection.

KOMATIITES are believed to represent ultramafic liquids which erupted at temperatures of 1,400–1,700 °C with estimated viscosities in the range 0.1–1 Pa s, and with MgO contents of 18–35%[1–3]. Such lavas are mostly of Archaean age. They indicate that thermal conditions of the early Earth were significantly different from those of today and provide insights into the composition of the Archaean mantle. They commonly exhibit spectacular spinifex textures and internal layering[4], and some are also the host to important nickel sulphide mineralization[5]. Interpretation of their chemical compositions, petrological and geological features and mineralization requires an understanding of their eruption, emplacement and cooling. As a contribution to this understanding, we present both a fluid dynamical analysis of the flow and cooling of komatiites and experimental studies which simulate the formation of spinifex texture in ponded komatiite lavas.

Recent basalts have eruption temperatures usually below 1,250 °C and viscosities >50 Pa s; almost all of them flow by laminar shear at low Reynolds number and cool by conduction. We propose that, because of their much lower viscosities, komatiites would have flowed turbulently at high Reynolds number, and would have cooled initially by forced convection. We suggest that, after emplacement, komatiite lavas still cooled rapidly by thermal convection and demonstrate, by experimental studies on cooling of saturated aqueous solutions, that convective effects can strongly influence the development of the characteristic spinifex textures.

Magma ascent

Magma ascends to the surface because of its buoyancy[6,7]. At high Reynolds number, Re, the two-dimensional discharge rate, Q, from a long fissure of width d can be estimated as

$$Q = \left(\frac{g\Delta\rho}{k\rho_m}\right)^{1/2} d^{3/2} \qquad (1)$$

where g is gravity, $\Delta\rho$ is the assumed constant density difference between the magma and the lithosphere overlying its source, ρ_m is the magma density, k is a friction coefficient which can assume values between ~0.01 and 0.06 depending on the surface roughness of the fissure[7], and the Reynolds number is

$$Re = Q/\nu \qquad (2)$$

where ν is the kinematic viscosity. In principle, in order to account for the density variation in the lithosphere, the compressibility of the melt and the tortuous nature of the fissure, a more elaborate treatment than that leading to equation (1) is required. However, the accuracy of equation (1) is sufficient for our calculations. At shallow depths in the lithosphere, the value of $\Delta\rho$ is ~300 kg m^{-3}, whereas at depths of 100 km the value of $\Delta\rho$ has been estimated as 100 kg m^{-3} (ref. 8).

Table 1 gives the values of Q, flow velocity $v = Q/d$, and Re for a plausible range of natural fissure widths. The komatiite is assumed to have a viscosity of 0.3 Pa s, a density of 2,800 kg m^{-3} and we have set $\Delta\rho$ to a conservative value of 100 kg m^{-3}. The value of 0.03 has been used for the friction coefficient. Table 1 shows that even for the narrowest fissure (0.3 m), Re greatly exceeds the critical value (equal to ~2,000) required for turbulent flow. Komatiites are thus likely to have flowed turbulently up the fissure before eruption. This should be compared with the largest historic eruptions of basalts, for which Q and Re are less than 10 m^2 s^{-1} and 600 respectively[7].

Table 1 The two-dimensional flow rate, Q, the vertical velocity, v, and the Reynolds number, Re in a fissure of width d

d(m)	Q(m^2 s^{-1})	v(m s^{-1})	Re
0.3	0.56	1.9	5.2×10^3
1.0	3.4	3.4	3.2×10^4
3.0	17.8	5.9	1.6×10^5
10.0	108	10.8	1.0×10^6

Lava emplacement

A fundamental feature of a turbulent flow is that the heat transfer is much greater than in a laminar flow, where heat is lost entirely by conduction. In turbulent flows, mixing maintains a uniform temperature throughout the span of the flow and greatly increases heat transfer to the surroundings. Thus, in turbulent komatiite flows the ground surface would be quickly heated up to temperatures of 1,600–1,700 °C. In greenstone belts, komatiites often flow over rocks, such as tholeiitic basalt and sediment[9,10], which have substantially lower melting temperatures. We suggest that komatiites could have melted and assimilated this underlying rock.

Our model, a geometric sketch of which is presented in Fig. 1, is related to that proposed by Hulme[11,12], who argued that the sinuous rilles on the Moon were caused by thermal erosion of lava channels by turbulent lunar flows. We consider flow on a shallow slope beneath a deep body of water. Both floor rocks and water have initial temperature T_0, which is taken to be 0 °C. The heat transfer from the komatiite, due to forced, turbulent convection, melts some of the ground which is then

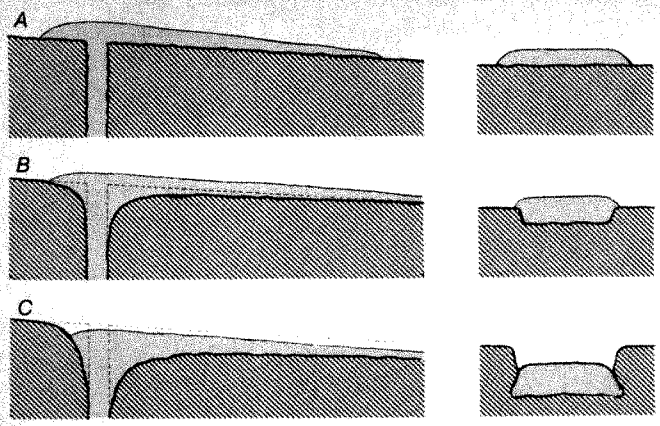

Fig. 1 Longitudinal and cross-sectional sketches of the fissure and lava flow showing the melting of the ground and the formation of an erosional channel with time.

assimilated. Efficient cooling by the water above the flow forms a thin crust on top of the lava and prevents any mixing between the two. As the lava cools, crystals form within it, which decreases the rate of cooling. The komatiite is assumed to flow in the form of a gravity current of high Reynolds number over a slope which is sufficiently small that its effects can be neglected. The thickness of the current, h, can then be determined[13] by

$$h = (\tfrac{1}{2}Q^2\rho_l/g\delta\rho)^{1/3} \quad (3)$$

where $\delta\rho$ represents the density difference (1,800 kg m^{-3}) between the komatiite and seawater. Table 2 presents the flow thickness, velocity, u, and Reynolds number for different values of Q. A gravity current with a Reynolds number greater than ~500 is fully turbulent[14]. The values in Table 2 indicate that this is the case for all komatiite flows.

At steady state the melting rate is given by[11,15]

$$\frac{dS}{dt} = \frac{H}{\rho_g[c_g(T_m - T_0) + L_g]} \quad (4)$$

where H is the heat transfer rate to the ground, ρ_g is the density of the ground, c_g is the specific heat of the ground, T_m is both the melting temperature of the ground and the solidification temperature of the komatiite and L_g is the heat of fusion of the ground. The heat transfer is related to T_l, the lava temperature, and T_m through a heat transfer coefficient, h_T, by[15]

$$H = h_T(T_l - T_m) \quad (5)$$

An approximation to the heat transfer coefficient can be obtained by modifying empirical relationships for turbulent pipe flows[15]. This leads to

$$h_T = 0.018\frac{k_l}{h}Pr^{0.4}Re^{0.8} \quad (6)$$

where k_l is the lava conductivity and Pr its Prandtl number.

Table 2 shows that transfer coefficients of between 500 and 1,000 W m^{-2} °C^{-1} result for flow rates in the range 0.5–100 m^2 s^{-1}. This variation in the heat transfer coefficient is fairly small and for simplicity we have taken $h_T = 750$ W m^{-2} °C^{-1} in the subsequent calculations. With the values of physical parameters listed below inserted into equations (4) to (6), the melting rate of the ground near the source is calculated to be 8.1×10^{-5} m s^{-1} (7 m per day), confirming that thermal erosion was a major effect during the emplacement of komatiites. (The physical parameters used were: $k_l = k_c = 1$ W m^{-1} °C^{-1}; $c_l = c_g = 730$ J kg^{-1} °C^{-1}; $\rho_l = 2{,}800$ kg m^{-3}; $\rho_g = 2{,}700$ kg m^{-3}; $L_g = L_x = 5 \times 10^5$ J kg^{-1}; $T_0 = 0$ °C; $T_m = 1{,}200$ °C; T_l $(x = 0) = 1{,}600$ °C; $\theta_0 = T_l$ $(x = 0) - T_m = 400$ °C; and $Pr = 219$.)

Table 2 Lava flow thickness, h, its velocity, u, the Reynolds number, Re, the heat transfer coefficient, h_T, and the coefficient modified by crystallization, h_T^x, as a function of Q

Q(m^2 s^{-1})	h(m)	u(m s^{-1})	Re	h_T (W m^{-2} °C^{-1})	h_T^x (W m^{-2} °C^{-1})
0.5	0.27	1.8	4.7×10^3	498	238
1	0.43	2.3	9.3×10^3	543	259
10	1.99	5.0	9.3×10^4	739	353
100	9.26	10.8	9.3×10^5	1,000	477

Table 3 The cooling rate at the source, $\dot{T}(0)$, the erosion rate at the source, $\dot{S}(0)$, and the length scale over which the temperature of the lava decreases, D^{-1}, as a function of Q

Q(m^2 s^{-1})	$\dot{T}(0)$ (°C h^{-1})	$\dot{S}(0)$ (m per day)	D^{-1} (km)
1	1,300 (2,730)	3.33 (6.98)	2.9 (1.4)
10	280 (590)	3.33 (6.98)	28.5 (13.6)
100	61 (127)	3.33 (6.98)	285 (136)

The second entry, in parentheses, is the value if latent heat effects are set equal to zero.

A thin crust forms at the contact with seawater. At the top of the crust the temperature is T_0, while at the bottom it is T_m. The crustal thickness, a, is determined from the fact that in a steady state the conductive heat transfer through the crust equals the heat transfer from the lava given by equation (5). Thus

$$a = k_c(T_m - T_0)/h_T(T_l - T_m) \quad (7)$$

where k_c is the conductivity of the crust. Near the source $a \approx 4$ mm and increases away from the source as the lava temperature decreases.

Cooling of the lava

Heat loss from the lava causes crystallization, which releases latent heat, L_x. A quantitative heat budget calculation indicates that the lava temperature as a function of downstream distance x is given by

$$T_l = T_m + \frac{D\theta_0}{(E\theta_0 + D)\,e^{Dx} - E\theta_0} \quad (8)$$

where θ_0 is the difference between the temperature of the lava at source and the melting temperature of the ground, $D = 2h_T^x/(\rho_l c_l Q)$,

$$E = \frac{h_T^x}{Q\rho_g[c_g(T_m - T_0) + L_g]} \quad (9)$$

and

$$h_T^x = \frac{h_T}{1 - L_x x'(T)/c_l} \quad (10)$$

with $x'(T) = -\frac{1}{625}$ °C^{-1} representing the rate of change of crystal fraction with temperature[16]. For $Q = 10$ m^2 s^{-1}, the lava temperature as a function of distance is plotted in Fig. 2A. The temperature decreases with a length scale given by D^{-1}, which is evaluated for other flow rates in Table 3. If the lava increases the ground temperature to T_m but does not melt it, its temperature is given by $T_l = T_m + \theta_0 e^{-Dx}$, also plotted in Fig. 2A.

The cooling rates of the lava flow for $Q = 10$ m^2 s^{-1} are plotted in Fig. 2B; one curve incorporates latent heat release due to crystallization while the other does not. With latent heat effects the cooling rate is 280 °C h^{-1} near the source and decreases steadily away from it. Initial cooling rates for other flow rates are given in Table 3.

These calculations assume that crystallization occurs in thermodynamic equilibrium, although experimental studies[17,18] on magnesian-rich basic melts show that rapid cooling rates can

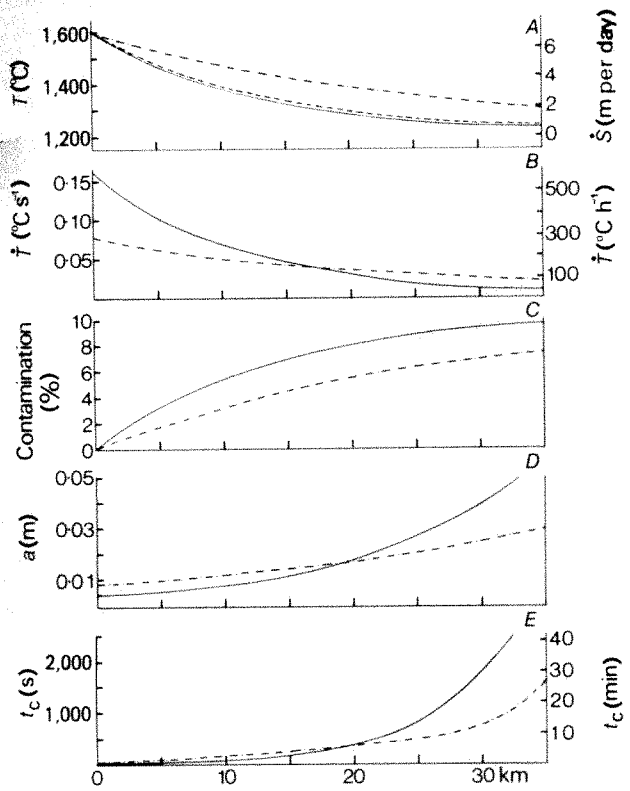

Fig. 2 *A*, The temperature of the lava, T, and the erosion rate of the ground, S. ——, With melting; – – –, without melting. *B*, The cooling rate; *C*, the percentage of contamination; *D*, the crustal thickness, a; and *E*, the time scale for the crust to form; all as a function of distance from the source. In *A*–*E* the dot–dash (– · –) line incorporates the latent heat release due to crystal formation, while the solid line omits this effect ($L \equiv 0$).

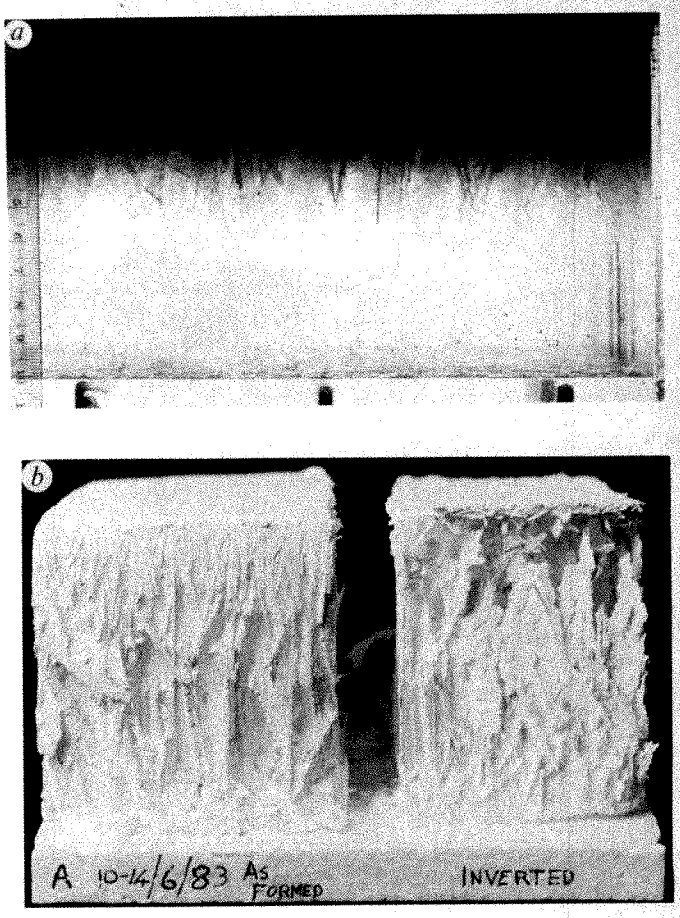

Fig. 3 Photographs of an experiment in which aqueous Na_2CO_3 was cooled from above. *a*, Photograph with back-lighting after 1 h 38 min. Note the growth of long crystals with nearly vertical orientation, followed by a layer of eutectic with a sharp horizontal boundary. The scale on the left indicates the distance (in cm) from the cooled roof. *b*, The subsequent crystal block after ice was allowed to melt and run out of the upright (left) and inverted (right) halves of the block.

cause large undercoolings. Extrapolation of Donaldson's experimental data[18] to cooling rates of several hundreds of °C per hour suggests undercoolings of 50–70 °C. The cooling rates in excess of 10^3 °C h^{-1}, for small Q, might result in considerable delays in olivine nucleation, with the extreme case of zero crystallization. Table 3 shows the results of calculations neglecting crystallization completely; cooling rates and melting rates increase as the undercooling increases.

As the melting rate of the ground is proportional to $T_l - T_m$, it has the same functional form as T_l (Fig. 2*A*). Our calculations indicate that one hour after eruption, with the flow rate $Q = 10\ m^2\ s^{-1}$, the channel depth at source would be 14 cm, while 15 km from the source it would be 8 cm. After a week the depth at source would be 23 m and 15 km from source it would be 13 m. If no crystallization occurred, the depths would be just over twice these values. If the lava flow were 250 m wide, the volume erupted after one hour and one week would be 9×10^6 and $1.5 \times 10^9\ m^3$, respectively. These volumes are comparable to small- and medium-sized basalt eruptions.

Assimilation of the melted ground contaminates the lava, as indicated in Fig. 2*C*. The contamination rises steadily to an asymptotic value of 10.4%, independent of the flow rate, and could significantly change the trace element and isotopic composition of the lava, although it would have only minor effects on the major element composition.

The crustal thickness, given by equation (7) and plotted in Fig. 2*D*, is of the order of a few centimetres, consistent with the geological evidence that komatiites often show an upper quench glassy zone of this magnitude[4]. The time scale for this crust to grow (Fig. 2*E*) is quite short and indicates that if at any time the crust is broken up by the turbulent flow beneath it and falls into the flow, a new crust forms fairly rapidly. Thus a steady-state crust caps the flow during almost all the emplacement period.

Post-emplacement processes

Once the supply of magma has ceased, the komatiite can be expected to drain into any available depressions, which would include the channel incised by thermal erosion. In many lavas only part of the cooling will have been accomplished during active flow and the ponded lava will continue to cool and crystallize. If the crust is thin, theoretical calculations (which will be presented in detail elsewhere) show that the ponded komatiite will continue to cool by thermal convection. By balancing the conductive heat flux across the crust with the convective flux in the interior, we obtain initial cooling rates of tens to hundreds of °C per hour. As the crust thickens from being a few centimetres thick, the lava temperature decreases and eventually turbulent convection will decrease in vigour. At this stage the heat budget is dominated by a balance between the conductive flux across the crust and latent heat release. We envisage that granular olivines suspended in the lava will now fall out to form the peridotitic cumulate layer, typical of the lower parts of many komatiites[10].

In order to simulate the development of spinifex texture, we crystallized saturated aqueous solutions by cooling from above. Figure 3 shows the results of cooling an aqueous solution of

12.3% anhydrous Na_2CO_3 in a cubical container initially at 31 °C by circulating alcohol at −30 °C through the top plate. Initially, vigorous thermal convection occurred and small dendritic crystals of hydrated Na_2CO_3 nucleated on the roof. At first the crystals showed a wide range of orientations with respect to the roof (Fig. 3*a*). As the experiment progressed, however, the crystals increasingly became oriented perpendicular to the roof (Fig. 3*b*). At the same time, a stagnant pool of less dense, residual fluid formed between the growing crystals due to compositional convection[19]. The tips of the crystals extended beyond this layer into the saturated, convecting fluid beneath. Experiments on other saturated solutions of Na_2SO_4 and KNO_3 mirrored these features, confirming that the general behaviour is not dependent on composition.

Geological interpretations

Our analysis shows that komatiites can become significantly contaminated by assimilation of the underlying rock (Fig. 2*C*). We emphasize three points concerning the contamination process. First, floor rocks will be quickly melted and efficiently mixed into the turbulent flow. Xenoliths would not be expected to survive. Second, the chemical signature of contamination would not be extreme; only elements strongly concentrated in the contaminant and depleted in the komatiite would be noticeably affected, and the evidence for this would be most apparent in measurements of the ratios of elements with different compatibilities. Third, the amount of contamination is strongly dependent on flow conditions and distance downstream. As most eruptions probably fluctuate in intensity, the amount of contamination is likely to be very variable even within one flow. Non-systematic variations with indices of olivine fractionation would be anticipated for those elements that are sensitive indicators of contamination.

An application of the thermal erosion model relates to the origin of nickel sulphide mineralization, which we suggest could have been formed by komatiites melting underlying sulphur-rich sediments. Contamination of 10% of a sediment containing 6% sulphur could increase the sulphur content of the lava by 0.6%. The sulphur forms an immiscible sulphide liquid which extracts nickel from the komatiite and segregates to the base of the flow[5]. The sulphide liquid could separate effectively even from the turbulently flowing lava because of its high density (~4,500 kg m^{-3}), especially if it coagulated to form large drops with high settling velocities.

At Kambalda in Western Australia, the nickel sulphide ores are found at the base of komatiite flows where the lavas are thickest[9]. The long linear depressions which the ores occupy have been interpreted as pre-existing features down which the lavas were channelled. However, it would then be expected that sediment would accumulate in the channels and be thickest in these areas, whereas sediment rarely underlies the thickest komatiite flows and nickel sulphide is present there instead[20].

This antithetic relationship between the occurrence of sediment and ore is consistent with the suggestion that the depressions are thermal erosion channels where the lava has digested the sediment and cut into underlying basalt. The model also avoids the problem of trying to explain why highly magnesian melts carry such high contents of sulphur[20]. Thus, this model explains many of the features of mineralization, such as the regional association of sediment and ore-bearing komatiites, evident throughout the Western Australia nickel province. It remains to be seen, however, whether the model is of more general applicability.

Our work also relates to the origin of the characteristic textures and layering of komatiite flows[21]. Skeletal olivine morphologies and mineralogical peculiarities, such as crystallization of clinopyroxene, appear to demand either high rates of cooling or melts undercooled by hundreds of °C[17,18,22]. Cooling rates, based on conductive models[23], are orders of magnitude less than the rates required by experimental studies of olivine growth[17,18]. Thus, it is difficult to see how the slow cooling rates characteristic of conductive models can cause these textures. Our analysis of the post-emplacement phase, combined with Donaldson's experimental results[17], indicates that rapid cooling rates and large undercoolings can be achieved. Our experiments also indicate that compositional convection can significantly influence the morphology of crystals growing from the roof. Skeletal and dendritic crystal morphologies and metastable crystallization could be a consequence of both thermal and compositional convection.

Our study suggests that during flow, high cooling rates cause either pre-existing phenocrysts to grow, or high nucleation rates. Granular equant olivines remain suspended during turbulent flow and initially on emplacement, when thermal convection might occur. As convective stirring diminishes in vigour, the olivines settle out to form a cumulate layer. Olivine crystals nucleate on the roof and at first grow as dendrites in many orientations. However, compositional convection causes a pool of differentiated melt to form between the crystals beneath the roof. As the pool develops, the tips of olivine crystals grow preferentially at the margins, as in the experiment, and the olivines increasingly grow perpendicular to the roof.

We conclude that komatiites probably flowed turbulently and cooled in part by convection. One consequence of this behaviour is that komatiites can melt and assimilate underlying rock to form deep thermal erosion channels. Assimilation of sulphur-rich sediments may result in the formation of nickel ore deposits. After emplacement, komatiites can continue to cool by thermal convection. Nucleation of crystals on the roof results in the development of spinifex texture. All these processes have important influences on the development of the characteristic geology, textures, geochemistry and mineralization of these rocks.

We acknowledge useful comments by I. H. Campbell, C. H. Donaldson, R. Kerr, R. W. Nesbitt, L. Wilson and G. Worster. Our research on komatiites, stimulated during visits to the Research School of Earth Sciences during 1982, is supported by a grant from the BP Venture Research Unit to H.E.H. and R.S.J.S.

3.2 Å structure of the copper-containing, oxygen-carrying protein *Panulirus interruptus* haemocyanin

W. P. J. Gaykema, W. G. J. Hol, J. M. Vereijken, N. M. Soeter, H. J. Bak & J. J. Beintema

Biomolecular Study Centre (BIOS), University of Groningen, Nijenborgh 16, 9747 AG Groningen, The Netherlands

For the first time, the three-dimensional structure of a member of the copper-containing class of oxygen-carrying proteins—the haemocyanins—has been determined. The structure of Panulirus interruptus *haemocyanin at 3.2 Å resolution shows that each subunit of the 450,000-molecular weight hexamer is folded into three domains, and that the binuclear copper site is situated in the centre of the second domain. Amino acid sequence comparisons suggest that the polypeptide fold of* P. interruptus *haemocyanin is common to all arthropod haemocyanins.*

OXYGEN is transported in living organisms by three completely different classes of proteins: haemoglobins, haemerythrins and haemocyanins. Several three-dimensional structures, and numerous amino acid sequences are known for haemoglobins and haemerythrins[1–7]. Haemocyanins have, so far, been much less well characterized at the atomic level. However, this picture is altering rapidly as recently a wealth of haemocyanin sequence information has become available[8–19]. Here the folding of the polypeptide chain of a haemocyanin molecule is presented for the first time.

Haemocyanins are large, non-haem, copper-containing proteins which occur freely dissolved in the haemolymph of many invertebrate species. Two major classes exist: molluscan and arthropodan haemocyanins, which have completely different molecular architectures. Arthropodan haemocyanins consist of hexamers, or multi-hexamers, with subunits of molecular weight (MW) ~75,000, while molluscan haemocyanins are cylindrical oligomers with subunits of molecular weight ~400,000 (refs 20–25).

The oxygen-binding centres of haemocyanins each contain a pair of copper ions and have been the subject of extensive spectroscopic analysis. It is generally believed that the oxygen-binding centres of arthropodan and molluscan haemocyanins are quite similar[25–27]. Furthermore, the spectrum of the binuclear copper-containing oxytyrosinase is remarkably similar to that of oxyhaemocyanin[28–30]. Other proteins are known also to contain binuclear copper sites, such as ascorbate oxidase, laccase and ceruloplasmin[31–33], so knowledge of the binuclear copper site in arthropodan haemocyanins may lead to a better understanding not only of these sites in molluscan haemocyanins but also of those in several enzymes.

We have investigated the haemocyanin of the spiny lobster *Panulirus interruptus*, an arthropod. It is one of the smallest haemocyanins known, but still has a molecular weight of ~450,000 (ref. 34). It is a hexamer, each subunit containing one copper pair required for its oxygen transport function[25,35]. The oxygen-binding properties of *P. interruptus* haemocyanin[34–37] exhibit a distinct cooperativity, as do those of all haemocyanins[25].

As is common among arthropodan haemocyanins[25], *P. interruptus* haemocyanin displays subunit heterogeneity[13]. At least three types of subunits occur, designated a, b and c (formerly called '94K', '90K' and '80K', see below). The crystals used for the X-ray studies were grown from native *P. interruptus* haemocyanin. When the crystals were dissolved it was found that they only contain a and b subunits, in roughly equal amounts (J. P. van Eerd, unpublished results). Although immunological data suggest that these two types of subunits differ in amino acid sequence by ~18% (ref. 38), their N-terminal sequences are very similar[13] and no problems were encountered in interpreting the electron density distribution. The polypeptide chain could be followed very easily in a 3.2 Å electron density map of a molecule with a molecular weight of nearly half a million even though for half of the reflections no heavy atom phase information was available.

Amino acid sequence

The amino acid sequence determination was carried out on subunit a of *P. interruptus* haemocyanin. This subunit was formerly called '94K' after its apparent molecular weight (94,000) on SDS-polyacrylamide gels[13]. This nomenclature has now been abandoned, because, as shown below, the number of residues appears to be ~660, indicating a subunit molecular weight of ~75,000. This agrees with earlier gel filtration and sedimentation equilibrium studies by Kuiper *et al.*[34].

As a starting point for the primary structure determination, limited proteolysis of subunit a was carried out[14]. This generated an 18K fragment, derived from the N-terminus of the subunit, a 71K fragment from the C-terminus and a glycopeptide from in between these two fragments. The apparent molecular weights of these fragments were determined from their mobilities on SDS-polyacrylamide gels. For the N-terminal fragment the molecular weight determined agrees well with its length of 160 residues. The 71K fragment, however, has ony ~485 residues, and its anomalous behaviour on SDS gels is not understood.

The tryptic fragments were subjected to further digestions, followed by amino acid sequence analysis. Parts of the amino acid sequence of *P. interruptus* haemocyanin, including previously published sequences[13–17], are presented in Fig. 1.

Crystal structure determination

The monoclinic crystals, studied at *p*H 4.5, contained the complete 450,000-MW hexamer in the asymmetrical unit[34,39]. The crystal structure of *P. interruptus* haemocyanin at 5.0 Å has been reported elsewhere[39]. These studies revealed the shape and the 32 point group symmetry of the hexamer, the orientation of the molecular symmetry axes and the molecular centre. No heavy-atom derivative information was used beyond 4 Å. The procedure for obtaining the ultimate 3.2-Å electron density map was as follows.

(1) The 36 heavy-atom sites of the K_2PtCl_4 derivative and the 70 *o*-mercury phenol positions known from the 5-Å studies were optimized, by the lack of closure-error refinement method[40], against the 4-Å native and derivative data sets, followed by phase[41] and electron density calculations.

(2) The resultant 4.0-Å multi-isomorphous replacement electron density map was subjected to six cycles of Bricogne's molecular replacement program for phase improvement[42]. The

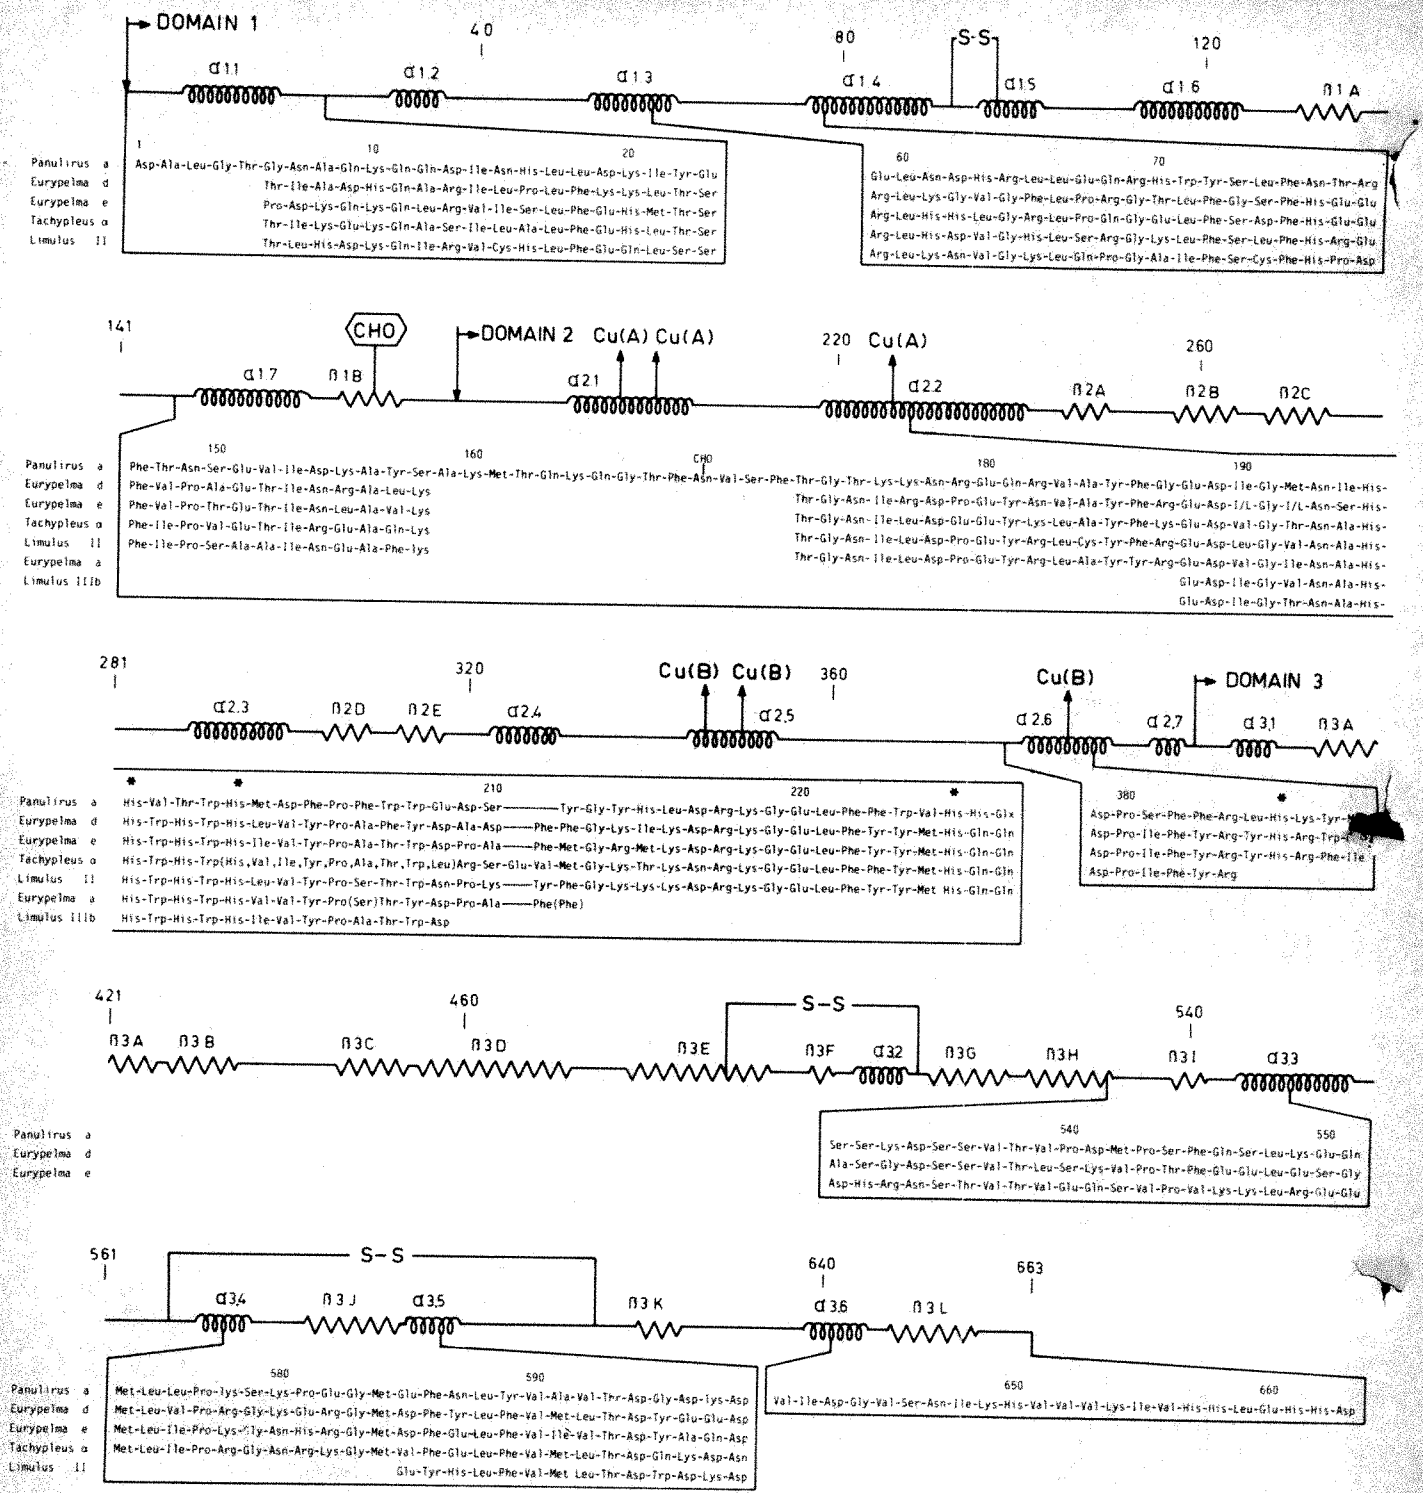

Fig. 1 Secondary structure and partial amino acid sequence of *Panulirus interruptus* haemocyanin subunit a, together with sequence information for several other arthropodan haemocyanins. The carbohydrate moiety (CHO), as well as the copper ligands (vertical arrows and asterisks) are indicated. The starting points of the different domains are indicated by the horizontal arrows. The α-helices are indicated by the coiled line, and the β-strands by the zig-zag. A two-character identifier is assigned to each α-helix and β-strand: the first character is the domain number, the second gives the position of a secondary structure element within its domain (for example, α 3.4 is the fourth helix in the third domain; β 2C is the third β-strand in the second domain). The amino acid numbering scheme must be considered as tentative, as the *P. interruptus* sequence is not yet complete and the number of residues cannot be established with certainty from the X-ray analysis at the present resolution. For the regions shown, the *P. interruptus* sequence data fit well into the electron density map. The disulphide bridges, indicated by S—S, are based on the electron density map, supported by the sequence information that residue 92 is a cysteine. The first and last three residues of the polypeptide chain are invisible in the map. Weak, but continuous, density occurs for residues 562–566 and 603–613. These weaker densities may be due to different courses of the polypeptide chain in the a and b subunit. Otherwise the entire polypeptide chain is well defined, including numerous side chains. As the N-terminal as well as the C-terminal fragments, of which the amino acid sequences are shown, could be unambiguously placed in the electron density map, as shown, there is no doubt that the complete polypeptide chain has been traced. For selected regions of the chain, apparently related amino acid sequences of other arthropodan haemocyanins are presented. The sequences shown are: *Eurypelma californicum* subunits d (ref. 12), e (ref. 11) and a (ref. 19); *Tachypleus tridentatus* chain α (ref. 8); and *Limulus polyphemus* subunits II (refs 9 and 10, and E. Yokota and A. F. Riggs, personal communication) and IIIb (ref. 19).

shifts in the phases (Table 1) and the improvement in the electron density map were considerable. The copper positions became evident at this stage[43].

(3) The phases obtained from Fourier inversion of the averaged electron density map were added to the known phases in thin shells of increasing resolution, containing 1,900–3,300 reflections. After one phase extension step, three cycles of density averaging and phase improvement were performed at constant resolution. Next, a new shell of reflections with unknown phases was added, and the procedure repeated. After the tenth and last extension step, 11 phase improvement cycles were performed.

The 3.2-Å data set contained 63,842 amplitudes, of which 31,121 had no heavy-atom derivative phase information. The statistics of the procedure are given in Table 1.

Polypeptide chain folding

The resultant 3.2-Å averaged electron density map proved to be of excellent quality (Fig. 2). It appeared possible to trace the complete polypeptide chain, to indicate disulphide bridges and to position several peptides for which the amino acid sequence was known (Fig. 1). The copper ions were by far the most prominent features of the map. The carbohydrate moiety[14,44] was clearly visible, as shown in Fig. 2.

A *P. interruptus* haemocyanin subunit folds its ~660 residues into an irregular ellipsoid of dimensions 48×55×80 Å, in accordance with electron microscopic data[20,22]. There are three distinct domains (Figs 3, 4). The first domain comprises 177 residues and is virtually all helical (Figs 1, 3*d*, 4*a*). A disulphide bridge occurs between residues 92 and 97. The last β-strand of the first domain is incorporated into a small, three-stranded β-structure together with two strands provided by one of the long loops of the third domain (Fig. 3*c*, *d*). This β-strand of domain 1 contains the single carbohydrate moiety of *P. interruptus* haemocyanin, which is covalently attached to residue Asn

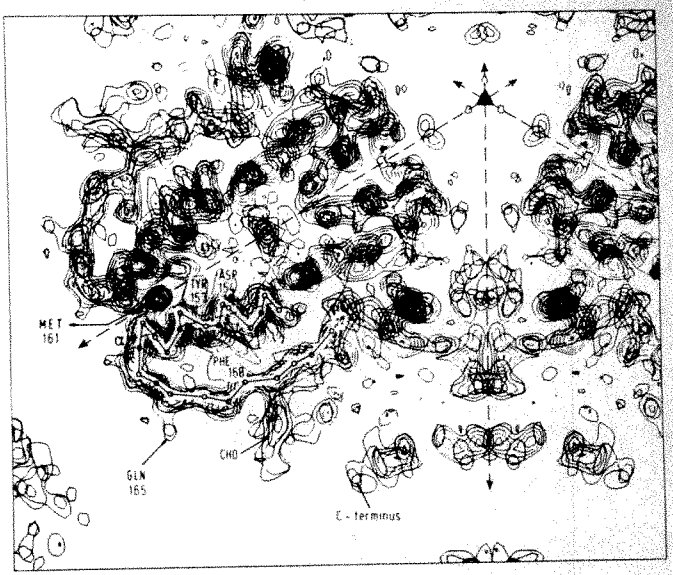

Fig. 2 Part of the ultimate, averaged, 3.2-Å electron density map. Five sections are shown through the centre of the hexamer, viewed along the local 3-fold axis of symmetry (▲). The thickness of the slab shown is 6 Å. As the hexamer obeys 32 point group symmetry[39], three local 2-fold symmetry axes occur in the central section, as indicated. For one subunit α-carbon positions in α-helix 1.7 and β-strand 1 B are indicated. CHO, the carbohydrate moiety. Some well defined side chains are labelled, and the same densities can be seen in the symmetry-related subunit. The course of the polypeptide chain can be followed without any difficulty, and numerous side chains have a well developed density. In the map actually used for chain tracing and peptide fitting, twice as many sections were used, at distances of 0.75 Å from each other.

Table 1 3.2-Å phase statistics

Resolution limits (Å)	No. of reflections	*R*-factor* (%)	Figure-of-merit†

For the double isomorphous replacement phases, out to 4 Å, the average figure-of-merit (as defined by Blow and Crick[41]) was 0.57 for 32,721 reflections. After six cycles of phase improvement by density averaging[42], the average figure-of-merit, as defined by Sim[66], was 0.76 with an average phase change of 60.4° with respect to the isomorphous replacement phases. The table provides statistics as a function of resolution after the phase extension (as described in the text) out to 3.2 Å. Molecular replacement programs were provided by Dr G. Bricogne and rewritten in FORTRAN 77 for the Cyber 170/760 of the Computer Centre of the University of Groningen, where all computations were performed.

* $$R = 100 \times \frac{\sum (|F_{P,calc}| - |F_{P,obs}|)}{\sum |F_{P,calc}|}$$

with

$$|F_{P,calc}| = k \exp\left[-B\left(\frac{\sin\theta}{\lambda}\right)^2\right]|F_{P,inv}|$$

where $|F_{P,inv}|$ is the structure amplitude obtained by Fourier inversion of the averaged electron density map; k and B are relative scaling and temperature factors obtained by a relative Wilson plot.

† The average phase difference between the phases after six cycles of molecular replacement at 4 Å resolution and the phases obtained by the multiple isomorphous replacement method.

169 (ref. 14). It appears that the carbohydrate moiety protrudes into a solvent region and does not, except for the first sugar group, make contacts with amino acid side chains. In this respect, the *P. interruptus* haemocyanin sugar chain is distinctly different from immunoglobulins[45], but similar to some carbohydrate chains in haemagglutinin[46] and neuraminidase[47].

The second domain, comprising residues 177–400, is also largely helical, but has a few β-strands (Figs 1, 3*e*, 4*b*). Four of these strands, 2B and 2C, and 2D and 2E, form antiparallel ββ-units. The oxygen-binding site is located in the centre of this globular domain, in between four helices. This site will be described in more detail later.

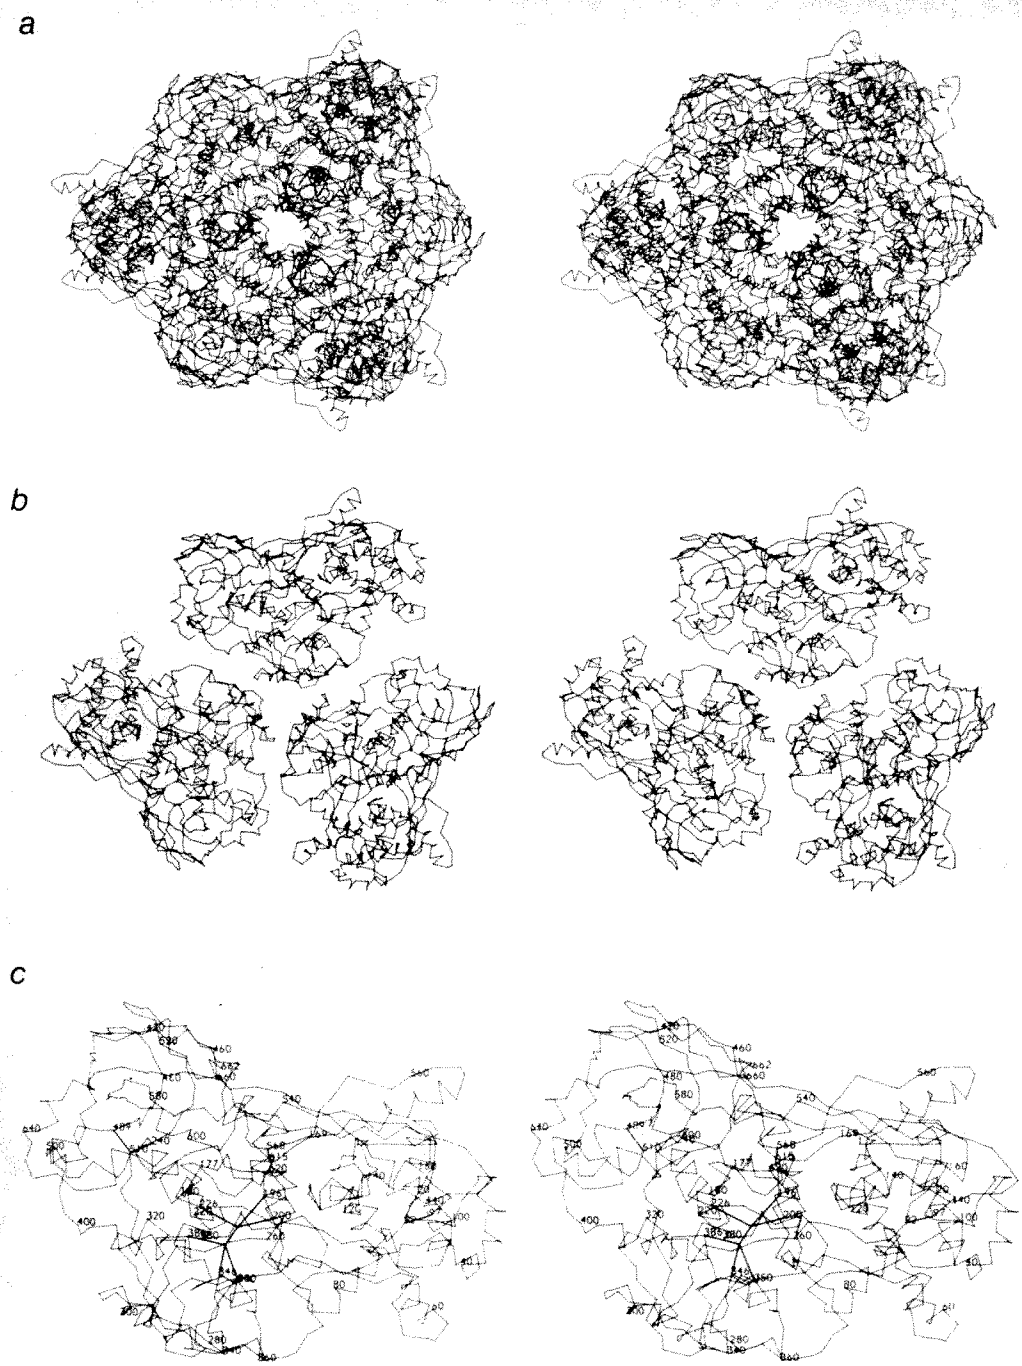
The third and largest domain consists of residues 400–663. From the central region of this domain extend long loops (Figs 3*f*, 4*c*) which appear to function as arms holding the three domains together (Fig. 3*c*). The central part of this domain is an antiparallel β-barrel consisting of seven strands. The electron density map indicates two disulphide bridges in this domain (Figs 1, 3*f*, 4*c*), giving a total of three disulphide bridges in each haemocyanin subunit.

Primary structure comparisons (Fig. 1) show that all three domains contain regions of similar sequence between haemocyanins of different organisms, which suggests strongly that the three-domain structure is a common feature of all arthropodan haemocyanins.

Figure 3*a* shows a stereoview of the hexamer and Fig. 3*b* the 'upper' trimer. In the hexamer, all three domains are involved in inter-subunit contacts. For instance, helix 1.7 is in contact with the same helix in a subunit related by a 2-fold axis (see Fig. 2). Helices 2.3 from three subunits interact with each other around the molecular 3-fold axis (Fig. 3*b*), and helix 3.6 is close to helix 1.3 of another subunit. As in haemoglobin[1,3] and haemerythrin[5–7], the contacts are all mediated by interactions between side chains—no hydrogen bonding interactions between backbone atoms occur.

The oxygen-binding site

The crystals that were used in the X-ray analysis were colourless, which suggests that we have determined the structure of the



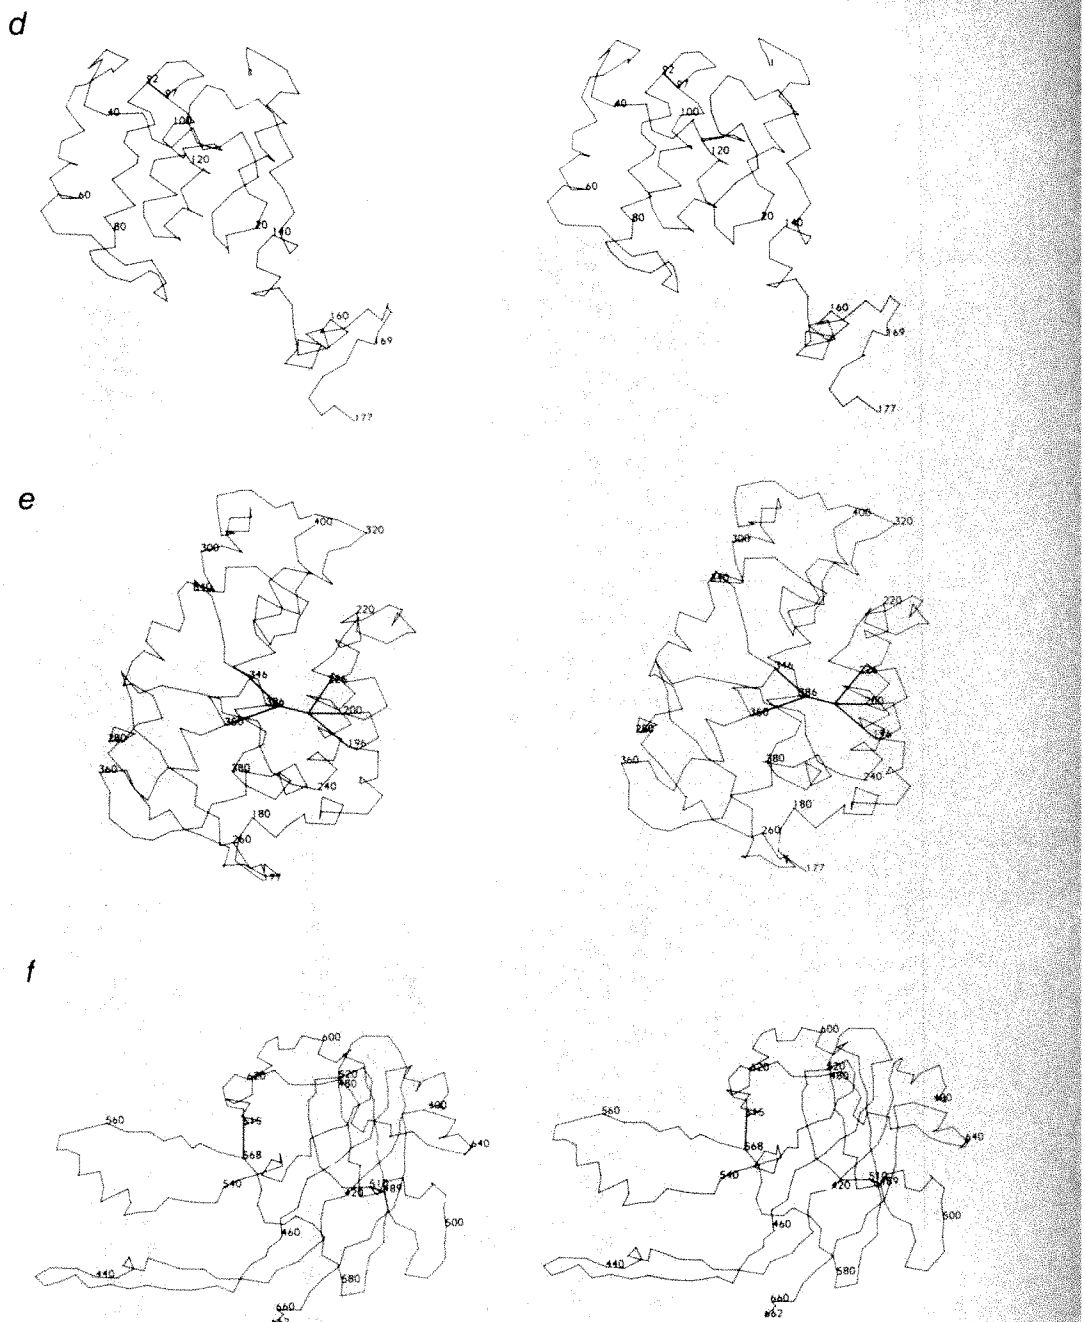


Fig. 3 The three-dimensional structure of *P. interruptus* haemocyanin in stereoscopic projection. Coordinates of the α-carbon, γ-sulphur and copper atoms were directly measured from a 3.2-Å electron density map, which was plotted on transparent sheets at a scale of 1 cm = 4 Å. Although the general course of the chain could be followed without difficulty, α-carbon coordinates of certain loops with less well developed side chains may be less accurate than that of other regions. ***a***, The complete hexamer, with a total of 3,978 residues, viewed along the molecular 3-fold axis. The three molecular 2-fold axes of this molecule with point group 32 (ref. 39) are in the plane of the paper. The hexamer can be described as two trimers, related by 2-fold axes and stacked face-to-face upon each other. ***b***, A view along the local 3-fold axis of the 'upper' trimer of *a*. ***c***, A view along the local 3-fold axis of one subunit only, with the same residues labelled as in *d–f*. Residue 169 contains the carbohydrate moiety. Residue 177 is the end of the first domain, and number 400 the end of the second domain. ***d***, The first domain only, in a view which gives a clear picture of the course of the polypeptide chain. The position of the first three residues is arbitrary as no density was visible in the electron density map. One disulphide bridge is indi-

deoxygenated form of haemocyanin. This is consistent with the low oxygen affinity of *P. interruptus* haemocyanin at low pH[48], and the absence of an absorption band near 340 nm in single-crystal UV spectroscopy (M. Vincent, unpublished data). However, we cannot rule out completely that the structure we have determined is of Met, or half-Met, haemocyanin.

It is clear from the 3.2-Å electron density map that each copper ion has three protein ligands. No evidence for a bridging protein ligand is found. One of the pair of copper ions, Cu(A), is surrounded by residues 196, 200 and 226; the other, Cu(B), is surrounded by residues 346, 350 and 386. Two of the ligands of Cu(A) come from successive turns of helix 2.1, and the equivalent two ligands of Cu(B) come from successive turns of helix 2.5. The third ligand of each copper ion also comes from a helix. The six copper ligands are thus provided by four helices. This is reminiscent of the situation in haemerythrins[5–7], but the topologies of the helices surrounding the oxygen-binding sites are different in these two classes of oxygen-binding proteins. Antiparallel helices both providing ligands for metal ions are also found in Fe-superoxide dismutase[49,50].

All six copper ligands in haemocyanin are almost certainly histidines. For four of the ligands (residues 196, 200, 226 and 386) this is clear from the fit of the *Panulirus* haemocyanin amino acid sequence with the electron density map. All other sequenced haemocyanins also have histidine residues at these positions, and very similar sequences in the surrounding regions (Fig. 1). The two remaining Cu(B) ligands have not been sequenced yet for *P. interruptus* haemocyanin. These two ligands must have the sequence L_1-X-X-X-L_2 according to the electron density map, with L_2 approximately 36 residues away from the third ligand. In the sequences of *Tachypleus* haemocyanin[8], and of two *Eurypelma* haemocyanin subunits[11,12] the arrangement His-X-X-X-His is observed precisely at the expected position. As the amino acid sequences of these haemocyanins are clearly related to that of *P. interruptus* haemocyanin in other regions (Fig. 1), it is justified to conclude that in arthropodan

cated by a virtual bond between the α-carbon atom of residues 92 and 97. Up to residue 155, this domain is quite globular, but residues 156–177 form an 'appendix' comprising helix 1.7 and β-strand 1 B. Helix 1.7 forms contacts via a 2-fold axis with another subunit as shown in Fig. 2. Strand 1 B contains the carbohydrate chain at position 169, and forms a β-structure with strands 3B and 3C of the long extended loop, 440–480, of the third domain (*c*). *e*, The second domain in a view allowing an easy following of the chain. The positions of the copper atoms are indicated and connected to the α-carbon atoms of the liganding residues. This domain is clearly globular and is mainly helical. The six protein ligands of the two copper ions are all histidines (see text). It should be emphasized that, at the present resolution, we cannot exclude the possibility of a small exogenous bridging ligand, such as a μ-oxo atom. *f*, The third domain oriented in such a manner as to highlight the two long excursions of the chain. Two probable disulphide bridges are indicated. It is quite obvious that this domain is far from globular. The long loops which extend from the central β-barrel make intimate contacts with the two other domains (*c*). The position of the last three residues is arbitrary as only weak density was present in the electron density map for these residues.

haemocyanins the two copper ions are liganded by six histidines. The involvement of the histidine cluster at position 195–200 in copper binding has been correctly suggested by Schneider *et al.*[19] and Yokata *et al.*[9]. That each copper atom has three ligands agrees well with the suggested model of the oxygen-binding site for deoxyhaemocyanin by Brown *et al.*[51] and Larrabee and Spiro[52].

The distance between the two electron density maxima representing the copper ions is 3.8 Å, with an error of ~0.4 Å. This corresponds well with the values derived from EXAFS experiments: 3.39 Å[51] for deoxyhaemocyanin; 3.67 Å[51] and 3.55 Å[53] for oxyhaemocyanin. The copper-binding centres in the subunits of a haemocyanin trimer (Fig. 3*b*) are separated by distances of 46 Å. The copper centres in one 'upper' subunit are separated from those in the three 'lower' subunits by distances of 47, 54 and 68 Å. Cooperative interactions between subunits thus must operate over quite large distances in *P. interruptus* haemocyanin.

Binuclear copper sites

No other three-dimensional structures are yet available for proteins with binuclear copper sites. However, the complete amino acid sequence of *Neurospora crassa* tyrosinase[54], a nearly complete sequence of human ceruloplasmin[32,33] and small fragments of the sequence of laccase[55,56]—all of which have binuclear copper sites—are known. Does the sequence His-X-X-His, which provides four of the ligands for each haemocyanin binuclear copper centre, occur in these possibly related proteins?

In tyrosinase this sequence does indeed occur: His 277 and His 281 are separated by three residues and are therefore possible copper ligands. Two other histidine residues in tyrosinase have been implicated by photo-inactivation as copper ligands: His 188 and His 193 (ref. 54). These occur in a sequence resembling that which provides two of the copper ligands in haemocyanin[9], but they are separated by four, not three, residues. This suggests that there are variations in the structure

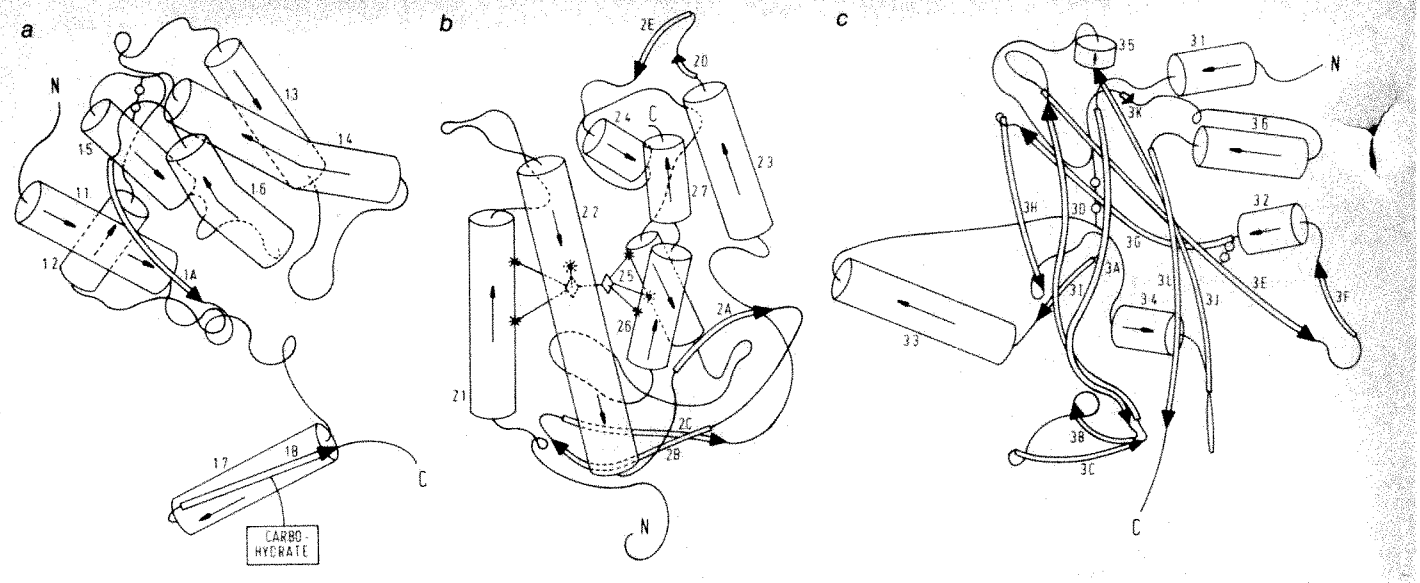

Fig. 4 The three domains of a subunit of *P. interruptus* haemocyanin depicted schematically, viewed from the same direction. ***a***, Domain 1: Helices are indicated by cylinders and β-strands by arrows. Secondary structure elements are indicated as in Fig. 1. A disulphide bridge is shown as —○—○—. The 'appendix' formed by helix 1.7 and β-strand 1B is evident. This β-strand contains the carbohydrate moiety. ***b***, Domain 2: The copper ions, which are located in the centre of this domain, are indicated by diamonds. All six ligands of the copper ions can clearly be seen to be provided by residues belonging to α-helices. It may be noted that the first ligand of Cu(B), residue 346 of helix 2.5, is situated at the very N-terminal turn of this helix. This is quite different from the first ligand of Cu(A), which resides in the middle of helix 2.1, and from the Fe-ligands in haemerythrin, which are also provided by residues from central parts of helices. ***c***, Domain 3: Two probable disulphide bridges are indicated by —○—○—. In this view, one long loop, comprising α3.3, extends to the left while another one, connecting β-strands 3B and 3C, extends to the back of this picture. (Drawings by A. Volbeda.)

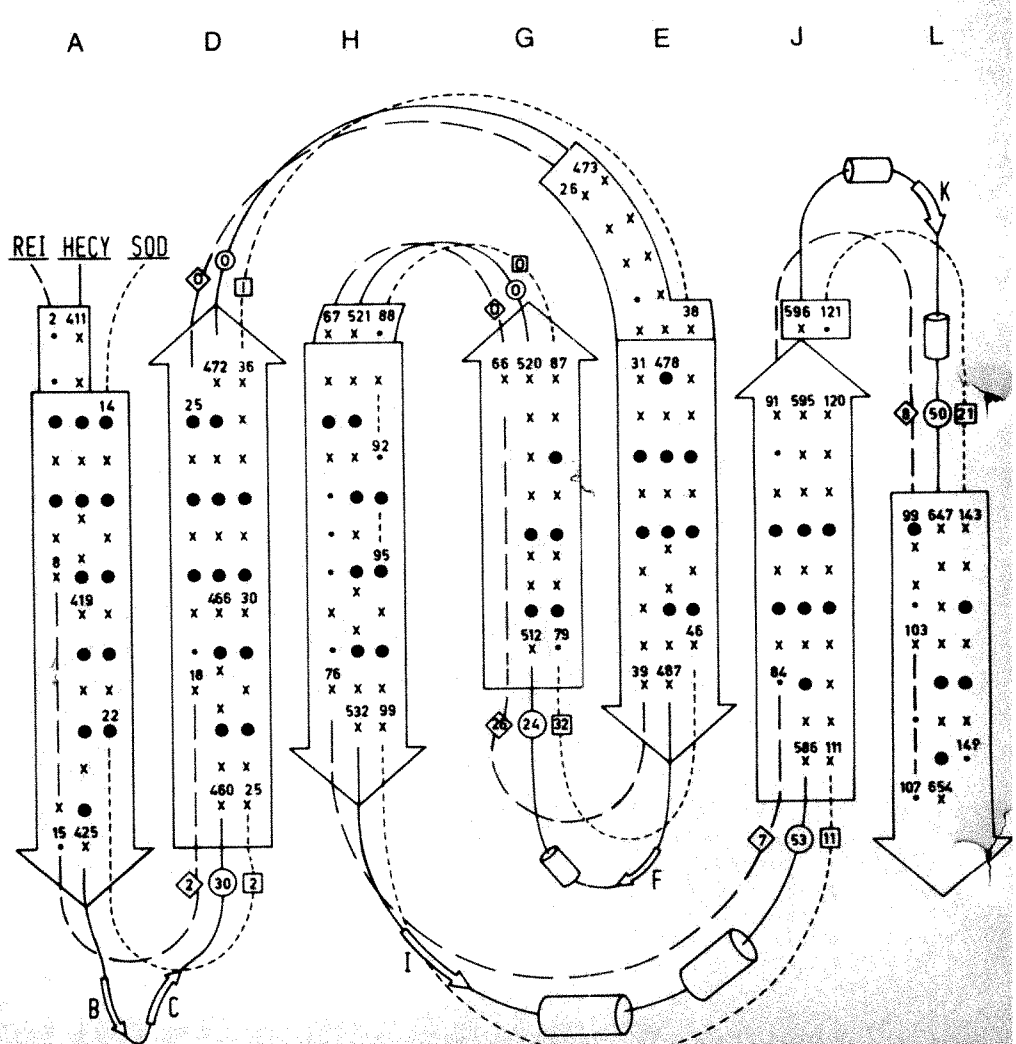

Fig. 5 Alignment of the equivalent amino acid residues in the β-barrels of Cu, Zn superoxide dismutase (SOD)[62], immunoglobulin REI (REI)[63] and the third domain of *P. interruptus* haemocyanin (HECY). The large arrows represent the seven β-strands which form the major part of the barrel. Equivalent α-carbon atoms which superimpose within 3.2 Å with haemocyanin are shown as large dots (●) and crosses (×). Equivalent α-carbon atoms deviating more than 3.2 Å but less than 4.0 Å are indicated by small dots (·). ● Indicate residues that point their side chains into the interior of the β-barrel. Residues marked by · or × do not point towards the interior. Strands G, E, J and L (haemocyanin numbering as in Figs 1 and 4) form one side of the barrel, strands A, D and H the other side. The lengths of the loops connecting the strands are also indicated: those of Cu, Zn superoxide dismutase in squares; those of immunoglobulin REI in circles; and those of haemocyanin in diamonds. (Drawing by A. Volbeda.) It appears that the third domain of haemocyanin has by far the largest loops. The loop connecting strands D and E is very similar in immunoglobulin REI and haemocyanin. The short loop connecting strands G and H is the same in all three cases. The three β-structures appear to resemble each other remarkably well (see text). For Cu, Zn superoxide dismutase and immunoglobulin REI, the coordinate sets 2SOD and 1REI from the Protein Data Bank[67] have been used for the superposition studies.

of the polypeptide chains surrounding these binuclear copper sites in different molecules, although spectroscopic data suggest that the copper environments are actually very similar[28–30].

In ceruloplasmin two pairs of histidines separated by three residues occur[32,33], and in the short sequence known of laccase[55] one such pair has been found. On the basis of the haemocyanin structure, these histidines may be binuclear copper ligands, although for ceruloplasmin other models have been suggested[32,33].

Molluscan haemocyanin structure

Knowledge of the oxygen-binding domain of arthropodan haemocyanins suggests a model for the molluscan haemocyanin structure. The subunit molecular weight of molluscan haemocyanins is ~400,000, with ~50,000 per binuclear copper site[20–22,25]. The arthropodan oxygen-binding domain, with ~223 residues, has a molecular weight of ~25,000. Spectroscopic evidence suggests that the oxygen-binding centres of molluscan and arthropodan haemocyanins are very similar[25–27]. The basic 50,000-MW unit in molluscan haemocyanins may therefore consist of an oxygen-binding domain similar to the one in *P. interruptus* haemocyanin, and a second domain which might correspond to the first or third *P. interruptus* haemocyanin domain. The two domains would be in quite intimate contact, forming a globular unit, while an array of eight such units makes up a complete molluscan haemocyanin subunit[57–59]. Similar relationships between the two haemocyanin classes have been suggested, on different grounds, by Van Holde[60].

Convergent evolution

The core of the third haemocyanin domain consists of a seven-stranded, antiparallel β-barrel. Surprisingly, the topology of this core is identical to that of the β-barrels in immunoglobulins and in Cu, Zn superoxide dismutase (Fig. 5)[61–63]. After optimal superposition of ~60 equivalent C^{α}-positions, the three barrels deviate mutually by less than 2.5 Å (r.m.s.).

However, when the available amino acid sequence for the β-barrel region of *P. interruptus* haemocyanin is compared with the sequences of the other β-barrels, hardly any similarities are observed. This is also the case when the β-barrel sequences of immunoglobulins and Cu, Zn superoxide dismutase are compared[61]. This β-barrel structure is probably an inherently stable structure, which allows great variability in length and folding patterns of the loops connecting the strands. The appearance of such β-barrels in domains with totally different functions suggests that the structural relationship is the result of convergent evolution.

Conclusion

The combination of X-ray diffraction and amino acid sequencing techniques described here has allowed the elucidation of the architecture of *P. interruptus* haemocyanin, which is probably common to all arthropodan haemocyanins. Furthermore, a detailed view has been obtained of the oxygen-binding site, which may share many features with the binuclear copper sites found in molluscan haemocyanins and several other proteins. Important questions remain to be answered, however, such as the nature of the contacts between the subunits of this hexameric protein, the structural changes that occur on oxygenation (fortunately, the X-ray analysis of an oxyhaemocyanin is under way[64,65]), and the relationship between the structures of arthropodan and molluscan haemocyanins. Once these questions are settled, then a complete picture will have been obtained of the three, or perhaps four, solutions nature has found for reversible oxygen transport in living organisms.

Cell attachment activity of fibronectin can be duplicated by small synthetic fragments of the molecule

Michael D. Pierschbacher & Erkki Ruoslahti

Cancer Research Center, La Jolla Cancer Research Foundation, 10901 North Torrey Pines Road, La Jolla, California 92037, USA

The ability of fibronectin to bind cells can be accounted for by the tetrapeptide L-arginyl-glycyl-L-aspartyl-L-serine, a sequence which is part of the cell attachment domain of fibronectin and present in at least five other proteins. This tetrapeptide may constitute a cellular recognition determinant common to several proteins.

FIBRONECTIN is a well characterized extracellular, structural glycoprotein which interacts strongly with other extracellular matrix molecules and which causes the attachment and spreading of most cells when presented to them as an insoluble substrate. This latter property is of considerable interest because an understanding of how cells interact with their surroundings may lead to an understanding of differentiation and of cell migration, for example, that which occurs during embryonic development or in tumour metastasis.

By using a monoclonal antibody which inhibits cell attachment, we have recently isolated, as a peptic fragment of molecular weight (MW) 11,500 (11.5K), the domain within the fibronectin molecule which endows it with the ability to interact with the cell surface of fibroblasts[1,2], and we have determined the complete amino acid sequence of this fragment[2]. This domain contained all of the cell attachment activity to be found among the proteolytic fragments of the fibronectin molecule[1]. By using synthetic peptides modelled from the sequence of this domain, we have described a 30-amino acid synthetic peptide which carries the cell attachment-promoting activity[3]. By using smaller synthetic peptides, we have now localized this function of the fibronectin molecule to a sequence of only four of these amino acids and we have shown that the same tetrapeptide is present in some other proteins which may interact with cells, including fibrinogen[4], a surface protein of *Escherichia coli*[5], and a Sindbis virus coat protein[6].

Cell attachment-promoting activity

The 30-amino acid synthetic peptide described previously placed the cell attachment site within the COOH-terminal quarter of the 108-amino acid cell attachment domain[3]. At that time, we predicted, by the method of Rose[7], that the cell attachment-promoting activity of the fibronectin molecule would probably be localized close to a hydrophilic stretch of amino acids near the NH_2-terminus of that peptide. Further analysis of the cell attachment domain, using methods for predicting secondary structure described elsewhere[8,9], showed that the group of residues boxed in Fig. 1 may be a β-turn which probably forms a hydrophilic loop at the surface of the molecule and is thus available to interact with the cell surface. To test whether these amino acids were involved in the cell attachment activity of the peptide, we obtained several synthetic peptides (Fig. 2*a*), coupled them to protein-coated plastic and tested each for cell attachment-promoting activity (Fig. 2*b*). All the peptides that promoted the attachment of rat kidney fibroblasts (NRK cells) contained the sequence Arg-Gly-Asp-Ser (or Arg-Gly-Asp-Cys) (Fig. 2*b*). The activity of the peptides decreased somewhat with size, perhaps due to a decrease in the stability of their conformation or to a relative inaccessibility on the substrate. The tetrapeptide, Arg-Gly-Asp-Ser, itself was active when immobilized on Sepharose beads at the end of a C_6 spacing arm (Fig. 3). Poor accessibility due to its small size or low efficiency of the coupling methods used for this peptide may account for the fact that we could not demonstrate activity in this peptide after coupling to protein-coated plastic.

Analysis of the data in Fig. 2 indicates that the serine residue of the tetrapeptide sequence can be replaced by a chemically similar cysteine residue without substantial loss of the activity (peptide IVA1a in Fig. 2). The activity was lost, however, when the arginine or aspartic acid residues were selectively deleted (Fig. 2) or if the synthetic peptides were cleaved at the arginine with trypsin (data not shown). Also, substitution of the glycine with the bulky valine residue (peptide RVDSPAC in Fig. 2) abolished the activity. Moreover, as can be seen in Fig. 4*a*, substitution of aspartic acid with asparagine greatly diminished the activity of the resulting tetrapeptide. We conclude from these results and from the data presented below that the Arg-Gly-Asp sequence must be maintained to preserve activity, while some variation at the position occupied by the serine residue is compatible with activity.

Inhibition of cell attachment

We were unable to inhibit the attachment of cells to fibronectin-coated surfaces with soluble fibronectin, nor could we inhibit such attachment with obtainable concentrations of the 30-amino acid, cell attachment-promoting synthetic peptide[3]. A possible explanation for this lack of inhibition is that the affinity of a

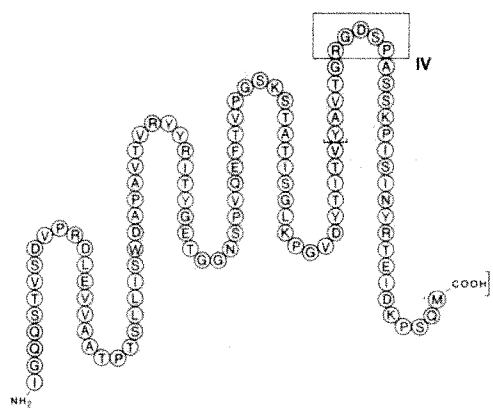

Fig. 1 Prediction of the secondary structure of the 11.5 K cell attachment domain of fibronectin. The methods of Chou and Fassman[8] and Kyte and Doolittle[9] were used to predict the probable secondary conformation of the cell attachment domain of fibronectin based solely on the primary structure[2]. The peptide consists of a series of potential β-turns, the most hydrophilic of which (boxed) is shown here to contain the cell attachment signal. Peptide IV, which was shown previously to contain the cell attachment activity[3], is enclosed in brackets. The one-letter code used to denote each amino acid is: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val; W, Trp; Y, Tyr.

single fibronectin molecule for the cell surface is so low that very high concentrations of soluble fibronectin or its fragments would be needed to overcome the cooperative interaction of many immobilized fibronectin molecules with cells. That this is the case has been suggested by the work of Grinnell and colleagues[10,11] and by that of Hughes *et al.*[12].

The small peptides, in contrast to fibronectin and its larger fragments, are highly soluble, which makes it possible to test them at millimolar concentrations for inhibition of cell attachment. For these tests we chose peptides which did not have a cysteine residue to avoid possible binding of the peptide to the substrate by disulphide exchange. We found that the Gly-Arg-Gly-Asp-Ser-Pro and Arg-Gly-Asp-Ser peptides did indeed interfere with the attachment of NRK cells to fibronectin-coated substrates (Fig. 4*a*). (In experiments where they were compared directly, the Gly-Arg-Gly-Asp-Ser-Pro peptide promoted cell attachment to surfaces coated with it to the same extent as did Gly-Arg-Gly-Asp-Ser-Cys.) The inhibition by the peptides occurred, in a dose-dependent manner, at peptide concentrations $>1\times10^{-4}$ M, (Fig. 4*b*). An affinity constant for the cell surface of 3×10^{-4} M and 6×10^{-4} M for the hexapeptide and tetrapeptide, respectively, was obtained using the method for estimating antibody affinity described by Müller[13]. Peptides not containing the Arg-Gly-Asp-Ser sequence showed no inhibition of cell attachment to fibronectin, indicating that the inhibition is specific and that inclusion of peptides in the cell attachment assay at these concentrations had no adverse effects on the cells. Furthermore, the attachment of cells to concanavalin A (Sigma) remained unaffected by the Arg-Gly-Asp-Ser-containing peptides (data not shown).

The tetrapeptide in other proteins

Having established the importance of the Arg-Gly-Asp-Ser sequence in fibronectin, we looked for this tetrapeptide in other proteins by searching the library of sequences compiled by the National Biomedical Research Foundation (George Washington University Medical Center, Washington, D.C.). This search revealed five proteins having the tetrapeptide (Table 1). Taking into account the frequency at which each of these four amino acids occurs in proteins and the 351,138 tetrapeptides examined from the sequence library, six such sequences would have been expected.

Of the five proteins having the active tetrapeptide sequence, fibrin(ogen) was of most immediate interest because of its demonstrated interaction with fibronectin[14] and the platelet surface[15,16]. Therefore, we tested a synthetic nonapeptide modelled on residues 568–580 of the α-chain of fibrinogen and found that it also promoted cell attachment Table 1 and Fig. 5). Attempts to demonstrate the attachment of our test cells to intact fibrinogen or fibrin, however, have not given clear-cut results. In accordance with earlier results[17], no attachment of fibroblastic cells to fibrinogen insolubilized on plastic could be demonstrated. Attachment of cells to the fibrinogen or fibrin polypeptides, separated by SDS-polyacrylamide gel electrophoresis and transferred to nitrocellulose as described elsewhere[18], gave only weak or, at times, no attachment to the separated α-chain (data not shown). In contrast, the activity of fibronectin is readily detectable in both conditions. It may be that the cell attachment site in fibrinogen is cryptic or destroyed during the assay procedures, or that the surrounding sequences

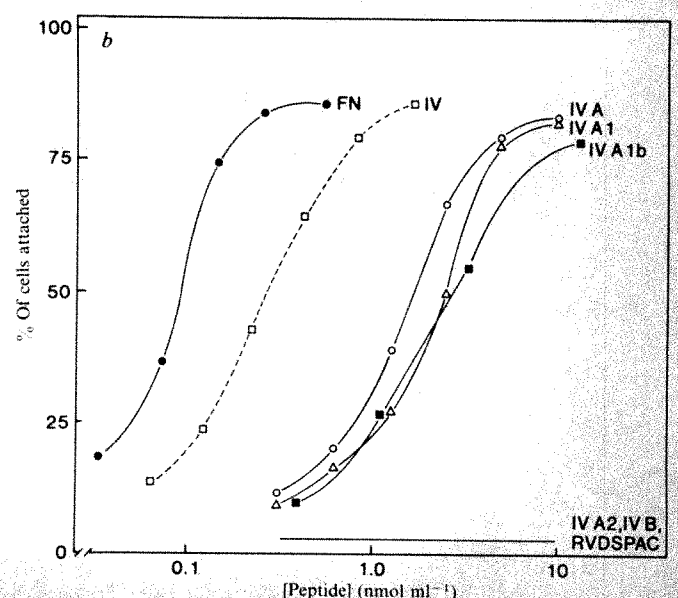

Fig. 2 Attachment of NRK cells to immobilized fibronectin and synthetic fibronectin peptides. ***a***, Peptides were synthesized by Peninsula Laboratories (Belmont, California) according to our specifications, to include a COOH-terminal cysteine (C). The activity of each peptide is indicated on the right of the figure by the concentration necessary to achieve 50% maximal attachment in the assay described below. ***b***, The synthetic peptides were assayed for their ability to promote the attachment of NRK cells by first attaching the peptides via the heterobifunctional cross-linker SPDP (*N*-succinimidyl-3-(2-pyridyldithio) propionate; Sigma) to rabbit IgG which had been immobilized on polystyrene[3]. By using radiolabelled peptides or antibodies to the larger peptides, we have determined that coupling of the peptides using this method is more than 85% complete (data not shown). Peptides not containing a cysteine are not included in the figure as the methods used to immobilize them appeared to be less efficient (see text). The attachment assay was carried out as described[35] using freshly trypsinized NRK cells. After incubation for 1 h at 37°C, those cells which had attached were fixed, stained and quantitated using either an Artek cell counter or a vertical pathway spectrophotometer. In all cases, maximum attachment was ~80–90% of the cells plated. The titration curves for whole fibronectin (FN) and peptide IV (ref. 3) are shown here for comparison.

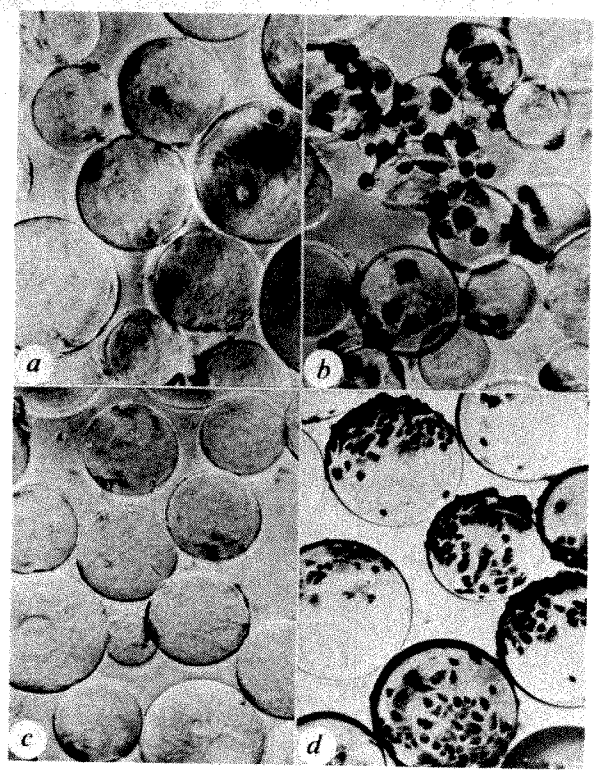

Fig. 3 Attachment of NRK cells to CH-Sepharose beads carrying tetrapeptides or fibronectin. Peptides TGRG (*a*), RGDS (*b*), GDSP (*c*) and fibronectin (*d*) were coupled to CH-Sepharose 4B (Pharmacia) by treatment of the Sepharose beads with 0.14 M 1-ethyl-3(3-dimethylaminopropyl)carbodiimide-HCl (Sigma) at *p*H 5–6 for 18 h at room temperature in the presence of a twofold molar excess of peptide relative to the available reactive groups on the beads. Coupling was quantitated by amino acid analysis and by monitoring the change in UV absorption. Each ml of Sepharose beads carried ~ 3–4 mg peptide or 10 mg of fibronectin. Attachment was assayed by incubating NRK cells with a monolayer of beads for 1 h at 37°C. The beads were then allowed to sediment (at 1 *g*) through 3 ml of 3% paraformaldehyde in phosphate-buffered saline to separate unattached cells and fix those cells which had attached. The unattached cells were decanted and the beads were stained with toluidine blue and observed under the microscope. *a*, *b*, and *c* ×50; *d* ×40.

A computer search through published protein sequences was conducted by The National Biomedical Research Foundation. The proteins having the sequence Arg-Gly-Asp-Ser are listed and the sequences flanking the tetrapeptide are shown. Residues identical to those found in the fibronectin sequence are boxed; chemically similar residues are enclosed in broken boxes; and sequences which were tested as synthetic peptides for cell attachment activity are shown in bold type. A synthetic nonapeptide was prepared from the fibrinogen sequence and was found to be active (see Fig. 5). The other proteins have not been tested (NT; see text for discussion of these proteins).

in some way weaken the activity of this site so that it is not recognized by fibroblastic cells in the intact molecule. The Arg-Gly-Asp-Ser sequence in fibrinogen is flanked on both the COOH-terminal and NH_2-terminal sides by sequences which are more hydrophilic than the hydrophobic regions present on either side of this sequence in fibronectin. On the other hand, platelets interact with fibrinogen[19,20] at more than one site within the molecule[21], and they also interact with fibronectin[22]. Future work should show whether the Arg-Gly-Asp-Ser sequence of fibrin is recognized at any stage of haemostasis by platelets or other types of cells, or whether this sequence might become uncovered on enzymatic dissolution of a blood clot. Future work should also show whether this sequence mediates the interaction of any of the other proteins listed in Table 1.

Implications

Our data show that the minimum signal necessary for the binding of cells to fibronectin resides in the short amino acid sequence Arg-Gly-Asp-Ser and that each of the four amino acids contributes to the binding. That this sequence is common to a few other proteins which may interact with cells implies that cells may use a single mechanism (receptor?) for interacting with several proteins. Although no structural basis for the surprising activity of such a small peptide is readily apparent, some of its properties are suggestive. As already mentioned, the tetrapeptide is found in a segment of fibronectin that would be very likely to form a hydrophilic loop at the surface of the molecule[8,9] and would thus be available to interact with cells. As in our hands polycations are relatively ineffective compared with the synthetic peptides in promoting the attachment of fibroblasts and even less effective in promoting cell spreading (M.D.P. and E.R., unpublished results), it is clear that binding is not due solely to the arginine residue. In any case, the other three residues of the tetrapeptide are clearly important because substitution of the glycine residue with valine eliminates cell attachment activity, and omission or substituton of the aspartate alters the activity of the peptide drastically (Fig. 4). Furthermore, we have tested a synthetic peptide taken from a sequence in collagen[23], Lys-Gly-Glu-Ser-Gly-Ser-Pro, and found no cell attachment promoting activity (data not shown), indicating that a mere conservation of the charge relationships (Lys-Gly-Glu . . . versus Arg-Gly-Asp . . .) does not maintain the activity.

We have also tested the activity of other peptides that resemble the Arg-Gly-Asp-Ser sequence and are present in collagens[23]. One such sequence, Arg-Gly-Asp-Thr-Gly-Ala-Thr-Gly-Arg, (taken from type I collagen) promotes cell attachment almost as well as the fibronectin peptides; two other sequences (taken from collagens of different genetic types[23]), Gln-Gly-Ile-Arg-Gly-Asp-Lys-Gly-Glu-Pro and Gly-Ser-Arg-Gly-Asp-Hyp-Gly-Thr-Hyp, when tested as synthetic peptides had no cell attachment-promoting activity at all (unpublished data). These results indicate that the serine residue is not essential but only conservative substitutions of this residue are compatible with activity. The sequences flanking the Arg-Gly-Asp-Ser sequence also affect activity as illustrated by the fact that the Gly-Arg-Gly-Asp-Ser-Pro peptide can inhibit cell attachment to fibronectin better than the Arg-Gly-Asp-Ser peptide.

The data we have obtained by selective substitution within the recognition sequence reveal some interesting possibilities about modification of the fibronectin activity in cells and tissues. Based on these results, one can infer that a single point mutation in the fibronectin gene (for example, one that would change glycine to valine; Fig. 2) could destroy the activity of the recognition sequence. This raises the possibility that there exist fibronectins which are ineffective cell attachment promoters. Moreover, the cell attachment sequence may be subject to modification by phosphorylation. Fibronectin has been shown to carry covalently bound phosphate[24–26]. A partially phosphorylated serine has been found elsewhere in the fibronectin molecule within a region not showing internal homology with the cell attachment domain[26]. However, the phosphorylated serine is homologous

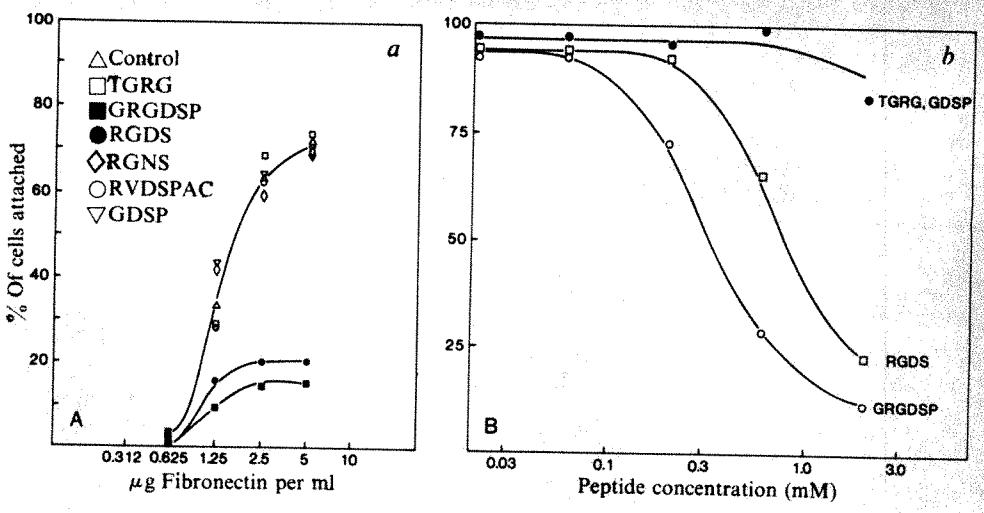

Fig. 4 Inhibition of attachment of NRK cells to immobilized fibronectin by synthetic fibronectin peptides. *a*, Microtitre wells were coated with decreasing concentrations of human plasma fibronectin, then non-bound fibronectin was washed away, and the attachment of NRK cells (10^4 cells per well) was assessed after incubation at 37 °C for 45 min in the presence of each of the peptides shown, each at a concentration of 1 mM. *b*, The peptides also were titrated in wells coated with 5 $\mu g\,ml^{-1}$ fibronectin. NRK cells were again incubated at 37 °C for 45 min, and attached cells were fixed, stained and counted. Incubation media for these experiments was Dulbecco's modified Eagle's medium (Flow) supplemented with glutamine–penicillin–streptomycin at 2 mM, 100 U and 100 $\mu g\,ml^{-1}$, respectively (Irvine Scientific) and bovine serum albumin 2 mg ml^{-1} (Sigma).

to the serine in the cell attachment site (compare Arg-Glu-Asp-Ser-PO_3 with Arg-Gly-Asp-Ser). Extrapolating from the data presented here, one would expect that the Arg-Glu-Asp-Ser sequence would not show cell attachment activity (compare Arg-Glu-Asp-Ser with Arg-Val-Asp-Ser). This agrees with our finding only one cell attachment site in each fibronectin polypeptide[1]. Whether the serine in the Arg-Gly-Asp-Ser sequence would be a suitable substrate for the same or a different protein kinase is unknown. In view of recent reports indicating the existence of cell surface protein kinase activity[27,28] and the finding of increased phosphorylation of fibronectin from malignantly transformed cells[29], this warrants further investigation. Phosphorylation could provide a means whereby cells might regulate their attachment and, where uncontrolled, could contribute to malignancy.

These results also raise the intriguing question of whether some prokaryotes and viruses use the fibronectin recognition sequence. The λ phage receptors on the surface of *E. coli* and Sindbis virus coat protein share a five-amino acid sequence with the cell attachment region of fibronectin (Table 1). It may be that some microorganisms use this sequence to interact with membranes of eukaryotic cells, and that some bacteriophages imitate the eukaryotic cell to gain entrance into *E. coli*.

The possibilities for future study discussed above are, at present, speculative. These possibilities, however, can be tested by using the peptides which inhibit cell attachment to fibronectin and, therefore, are also likely to interfere with other interactions which use this same recognition sequence. The peptides also provide us with the ability to specifically inhibit the cell attachment function of fibronectin, making it possible to study this function independent of the other functions of the protein in a variety of systems such as differentiation, cell motility, and in models of tumorigenesis and metastasis, all of which appear to be influenced by fibronectin[30–32].

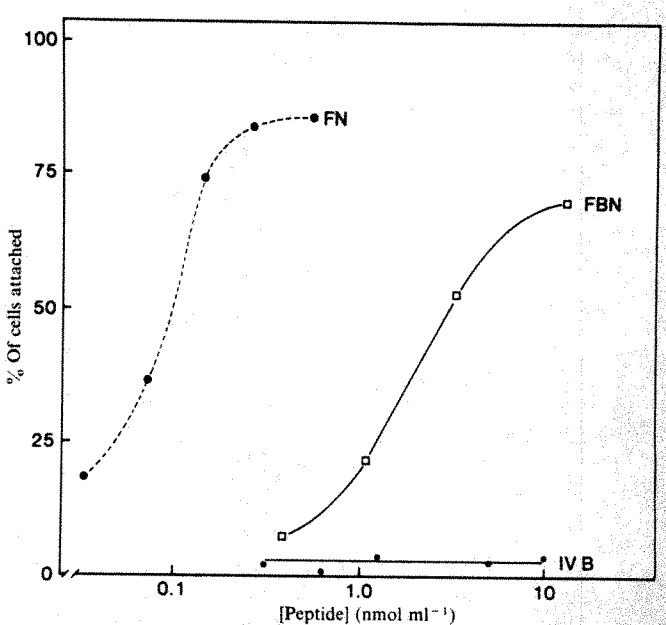

Fig. 5 Attachment of NRK cells to an immobilized synthetic peptide based on a sequence in fibrinogen. A synthetic fibrinogen peptide (FBN; see Table 1) was used to coat microtitre wells and was assayed for cell attachment as described in Fig. 2. Coating concentration of the peptide is indicated on the abscissa. The activities of fibronectin (FN) and peptide IVB are included for comparison.

We thank Yvonne Ohgren for technical assistance, Drs E. Hayman and E. Engvall for helpful discussion and Dr E. F. Plow for comments on the manuscript. This work was supported by grant CA 28896 and Cancer Center Support Grant CA 30199 from the NCI, DHHS.

The Sunyaev–Zeldovich effect towards three clusters of galaxies

M. Birkinshaw & S. F. Gull

Mullard Radio Astronomy Observatory, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, UK

H. Hardebeck

Owens Valley Radio Observatory, California Institute of Technology, Pasadena, California 91125, USA

An unequivocal detection of the Sunyaev–Zeldovich effect[1], the cooling of the brightness temperature of the microwave background radiation towards the atmospheres of clusters of galaxies, has profound cosmological significance[2–6], but has hitherto proved elusive. We present here measurements of the effect towards three rich clusters of galaxies made with the 40-m telescope of the Owens Valley Radio Observatory at 20.3 GHz. These results are three times more sensitive than other results previously reported[7–9], are free from systematic errors at the 100 μK level, and provide very strong evidence for the reality of the Sunyaev–Zeldovich effect.

The consensus of observational data supports the presence of a Sunyaev–Zeldovich effect towards only three clusters of galaxies—0016+16, Abell 665 and Abell 2218—although the support is by no means unqualified[7–9]. To provide further evidence for the reality or otherwise of the effect, we have worked for several years with the 40-m telescope of the Owens Valley Radio Observatory of the California Institute of Technology. Our results to 1983 January are reported elsewhere[10], but here we present the results of a successful observing run at 20.3 GHz made during the period 21 December 1983–3 January 1984.

For these observations, the 40-m telescope was equipped with a tunable K-band maser receiver with bandwidth ~400 MHz which provided an overall system noise temperature ~40 K. At our observing frequency the 40-m telescope has a beam efficiency of about 0.48, and a half-power beamwidth of 107 arc s. Observations were made using a symmetrical beam-switching scheme[10] with a beam-separation of 7.15 arc min. The weather was mostly good during our allocated observing period, and 237 h of useful data were obtained for the three clusters of galaxies 0016+16, Abell 665 and Abell 2218, and for nine reference regions of 'blank' sky located adjacent to the clusters or distant from them. These reference regions provide strong controls on the presence of systematic errors, which have severely handicapped earlier observations[11]. The data obtained from these observations were reduced using a modified form of the analysis of the variance[12]: tests with partial data-sets analysed in different ways gave consistent results. A test for parallactic-angle dependent systematic errors was also made[10], but none was found.

The results of these observations are given in Table 1, which contains the results for all the clusters and reference regions observed. The N and S positions associated with the clusters refer to points 7 arc min north and south of the cluster centres (the C positions, whose coordinates are given in ref. 10) respectively. The 0016+16 S position is contaminated by the presence of a nearby radio source whose contribution to the brightness temperature at this location is calculated (from lower-frequency measurements) to be 510±120 μK (refs 9, 13 and R. Laing, personal communication), and the brightness temperature measurement at this point has been corrected for this contribution. No corrections for the presence of radio sources have been applied to any of the other results in Table 1.

Because these observations were made using symmetrical beam-switching in azimuth, the ΔT_{RJ} brightness temperature measurements given in Table 1 represent the differences between the brightness temperatures towards the nominal points observed and the averages of points located on 'reference arcs' one beam-separation away, convolved with the primary beam-pattern of the telescope. For each cluster centre, the ΔT_{RJ} value therefore represents a measurement of a constant signal of ~0.45 of the central microwave decrement, ΔT_0 (using X-ray core sizes, θ_{cx}, of 0.50, 0.92 and 0.97 arc min for 0016+16, Abell 665 and Abell 2218 respectively, and a model

$$\Delta T_{RJ}(\theta) = \Delta T_0(1+\theta^2/\theta_{cx}^2)^{-\frac{1}{4}}$$

for the angular distribution of the decrement[10]). For the N and S reference locations, the reference arcs are located asymmetrically with respect to the cluster centres, and hence the cluster gas distributions, and cross the cluster centres at parallactic angle 90°. Averaged over the observational parallactic angle coverage, this implies that the N and S reference positions in these three clusters should see signals of only a few per cent of ΔT_0 appearing as small decrements or enhancements in the brightness temperature of the background radiation.

The differences between the values of ΔT_{RJ} measured at the cluster centres and at the N and S reference positions should, therefore, represent between 0.42 and 0.48 ΔT_0, and the significant depression of the C-position values of ΔT_{RJ} below those measured N and S of the cluster centres demonstrates the existence of significant Sunyaev–Zeldovich coolings towards each of the three clusters of galaxies.

Taking account of the parallactic-angle coverages of the observations, we can estimate for each cluster both the central microwave background decrement, ΔT_0, and any residual (constant) systematic offset signal, ΔT_s. These are given in Table 2. The values of ΔT_s are consistent with our limit of 100 μK deduced from the blank-sky results, but differ from zero at the 10% significance level even when correlations between ΔT_s and ΔT_0 in the fit are taken into account. For comparison Table 2 also gives the values of ΔT_0 deduced on the assumption that $\Delta T_s = 0$. Some small ΔT_s might be caused by pointing uncertainties or by the use of an inadequate model for the cluster atmospheres. Independent evidence for ~100 μK offsets has been found in other sensitive observations of the microwave background radiation using the 40-m telescope (A. C. S. Readhead, personal communication).

The values of ΔT_0 given in Table 2 correspond to significant detections of the Sunyaev–Zeldovich effect in each of these three clusters. The consequences of the detection of decrements with $\Delta T_0 = -0.7$ to -1.4 mK have been discussed elsewhere[10]—we note in particular that the very significant (8σ) detection of a

microwave background decrement towards 0016+16 may provide a useful cosmological test[2–6].

We conclude that there should be no further doubt of the reality of the Sunyaev–Zeldovich effect in these three clusters of galaxies.

We thank Tony Readhead, Al Moffet and Rich Moore for the provision of the receiver systems that we have used and the continued allocation of telescope time to this project. Research with the 40-m telescope of the Owens Valley Radio Observatory is supported by the NSF under grant AST82-10259.

Alignment of distant radio sources

R. H. Sanders

Kapteyn Astronomical Institute, Landleven 12, Postbus 800, 9700 AV Groningen, The Netherlands

A typical extragalactic radio source is a simple double or elongated structure with a well-defined orientation on the sky. In 1972, Willson[1] investigated the relative orientation of 74 extragalactic 3C radio sources mapped at the Cambridge 1-mile telescope, and noted that extended extragalactic radio sources tend to be parallel if they are separated by less than 10° on the sky. Since 1972, many more radio sources have been mapped with resolutions 10–20 times greater than that of the observations available to Willson. I have therefore reinvestigated this problem in two separate and largely independent samples of some 300 sources each, and report here that the alignment is present to a high significance level, provided that only the more distant sources are considered. The effect could be due to gravitational imaging if most of the matter in a closed universe is in thin filaments.

In brief, the technique used by Willson is as follows. For a pair of radio sources one first determines the angular distance, D, measured along the great circle connecting the sources. If the axes of the radio sources make angles α and β with the connecting great circle, then the angle between the radio sources is defined as $X = \alpha - \beta$ reduced to the interval $0, \pi/2$. If $X = 0$, the sources are parallel; if $X = \pi/2$ they are perpendicular. Given N sources with measured position angles, one may calculate $\bar{X}(D_1, D_2)$ which is the mean value of X for all n_p pairs with separations between D_1 and D_2. If there exists no correlation of position angles, the distribution of X is uniform between 0 and $\pi/2$, and $\bar{X}(D_1, D_2) = 45° \pm 45°/\sqrt{3n_p}$.

Willson found that for all pairs with $D > 10°$ in his sample, $42° < \bar{X}(D) < 50°$. But for close pairs, $\bar{X}(D < 10°) \approx 36°$, which, given his relatively small number of close pairs was about two standard deviations below the expected mean of 45°. The probability of a 2σ fluctuation in his 11 separation intervals is about 10% which is, roughly, the significance of the effect.

The first of the samples studied here consists of published maps of identified extragalactic radio sources. The sample contains most of the 3C objects listed in the compilation of Laing *et al.*[2] with the position angles taken from the references therein, primarily from the Cambridge 5-km surveys[3–7]. The sample also contains objects from a published quasar survey[8] (mostly 4C objects) including more than 100 quasars observed at the Very Large Array (VLA) at resolutions of 1–2 arc s as well as a number of additional quasars compiled from earlier surveys[9–11]. Source position angles were measured directly from the maps in most cases, and strongly distorted sources with ambiguous position angles were excluded. Following Willson an additional selection criterion is applied to objects mapped with one-dimensional arrays. A source is removed from the sample if its angular size is smaller than two north–south half-power beam-widths because inclusion of such sources would introduce an east–west bias in the position angle distribution.

With these conditions the total sample consists of 320 sources, of which 177 are identified with quasars and 143 with radio galaxies. Carrying out the analysis described above, I find only a very marginal effect. For separations smaller than 5°, $\bar{X}(D < 5°) = 42.76°$, which is a fluctuation of 1.33σ below the expected value of 45°. But considering only the sources with redshifts greater than 0.4 (191 sources) the results are quite different, as seen in Fig. 1 which is $\bar{X}(D)$ binned in 5° intervals. Here we find that $\bar{X}(D < 5) = 36.37°$, which is a deviation of 3.4σ. The distribution of X for all sources with separations smaller than 5° is shown in Fig. 2. This distribution obviously deviates significantly from uniform with more sources tending to be parallel. From the Kolmogorov–Smirnov test[12] the probability that the

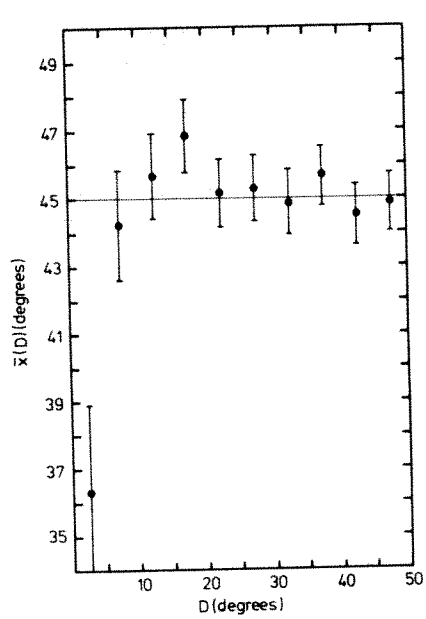

Fig. 1 The mean angle between radio sources in degrees as a function of angular separation in degrees for all sources in the 3C–4C sample with $z > 0.4$. The average is taken over 5° intervals and the error bars indicate the ± standard deviation for a uniform distribution ($45°/\sqrt{3n_p}$ where n_p is the number of pairs in a bin).

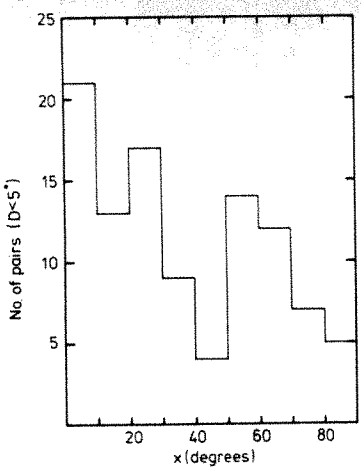

Fig. 2 The distribution of X, the angle between sources, for 102 pairs of sources in the 3C–4C sample closer than 5° on the sky and with $z > 0.4$.

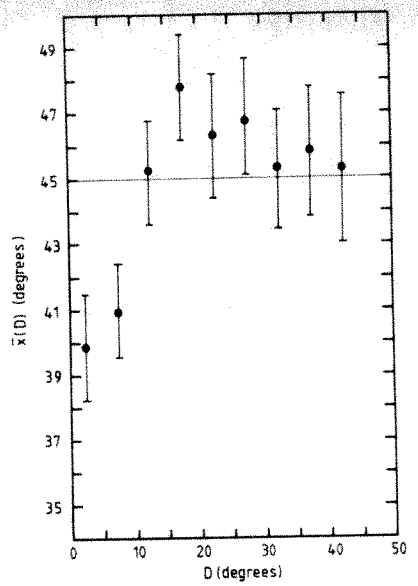

Fig. 3 The same as Fig. 1, but for all sources in the B3 sample smaller than 42 arc s.

observed distribution of angles between closely separated sources is drawn from a uniform random distribution is 0.003. This has been verified by Monte Carlo simulations in which source positions are unchanged but position angles are scrambled. The probability of finding such a large deviation over the entire range of separations (0°–50°) is roughly 10 times larger or about 3%.

As all sources in this 3C–4C sample have measured or estimated redshifts, it is possible to determine whether or not sources in nearly parallel pairs at close separations are at the same distance. There are 34 pairs in which the sources are closer than 5° and are parallel to within 20° (that is, $D < 5°$, $X < 20°$). The distribution of Δz, the redshift difference between the two members of these pairs, does not differ significantly from that of 34 pairs drawn randomly from the sample. For only four of these pairs is $\Delta z < 0.1$. This implies that the nearly parallel sources with $D < 5°$ which produce the effect are in general not physically close together.

A second largely independent and more homogeneous sample is provided by recent VLA observations of more than 1,000 sources selected from the third Bologna survey (B3) (R. Perley, B. G. Clark, A. H. Bridle and G. Greuff, in preparation). All mapped sources lie within a narrow declination range (38°–48°), and the observations were done in a mode which assured a circular beam with a half-power width of 14 arc s. Therefore there should be no systematic false effects resulting from an elongated beam. Of the mapped sources roughly one-third have structure on a scale larger than the beam. Position angles were measured for 297 sources with simple double or linear structure. Most of the sources in this sample are unidentified so redshift restrictions cannot be made.

In the complete sample there is no tendency for alignment. For separations less than 5°, we find $\bar{X}(D < 5°) = 44.66°$, which is within 1 s.d. of the expected value. Although a redshift restriction is not possible for the B3 sample, an angular size restriction is in some sense equivalent. By eliminating large sources from the sample, one eliminates nearer sources although the sample is still contaminated by small nearby sources. If all sources larger than 42 arc s (three beam widths) are removed, the results are shown in Fig. 3 which again is $\bar{X}(D)$ averaged in 5° bins. Although there are only 94 sources smaller than 42 arc s, there are still many close pairs because of the very restricted sky coverage of the survey. Here again we see a very significant tendency toward parallelism at small separations: $\bar{X}(D < 5°) = 39.84°$, or a 3.2σ deviation. Moreover, in this sample, the effect of alignment seems to extend to 10° with $\bar{X}(D < 10°) = 40.48°$, a 4.3σ deviation. The distribution of X for pairs separated by less than 10° deviates from uniform at the level of 7×10^{-5} (data not shown). The probability for finding such a large deviation at any separation is 0.1%.

Any subtle instrumental effect which might produce a spurious alignment (such as, for example, some aspect of the telescope side-lobe pattern giving greater sensitivity for extended structure in certain orientations) would be expected to show up as a non-randomness in the distribution of position angles. In both restricted samples taken separately the distributions of position angles do deviate somewhat from uniform at significance levels of about 10%. To test whether or not non-uniformity of the position angle distributions of this order could result in apparent alignment of closely separated sources, I have generated random skys in which the overall distribution of position angles is exactly the same as that observed; that is, the position angles are not scrambled but redistributed among sources. The frequency of chance alignments as significant as those observed is less than 1/1,000 in both samples implying that the effect does not result from non-uniformity in the global position angle distribution. It is more likely that the small non-randomness seen in the position angle distribution is an effect of the presence of several groups of closely separated well-aligned sources in samples of 100 to 200 objects.

The fact that the very pairs of objects which give the effect its high significance are widely separated in space (at least in the 3C–4C sample) implies that the effect arises along the line-of-sight. A possible explanation is gravitational imaging by superclusters[13]. Superclusters seem to be generally linear structures 10 to 100 Mpc in length[14]. The amplification produced by linear lenses is one-dimensional; the image of a background source is stretched in a direction perpendicular to the supercluster axis. One-dimensional amplification of a group of randomly oriented background sources can produce significant net alignment if most of the matter in an $\Omega_0 = 1$ universe lies in thin (<1 Mpc) long (~50 Mpc) filaments[13].

In view of the possible cosmological implications it is imperative that the effect should be confirmed. Remapping of the B3 radio sources at a resolution of 1–2 arc s is underway at the VLA and should definitely establish (or rule out) the reality of the apparent alignment. An additional experiment would consist of mapping all the radio sources down to some low flux limit in a small region of the sky (a $3° \times 3°$ field for example). If the effect is real, then the distribution of source position angles should deviate significantly from uniform.

Much of this work was done while I was visiting the NRAO in Charlottesville, Virginia. I thank M. S. Roberts for his hospitality and R. Perley and B. G. Clark at the VLA for providing their unpublished maps of B3 sources. I also thank A. H. Bridle, R. D. Ekers, J. H. Oort, T. Oosterloo, and especially T. S. van Albada for useful discussions and advice.

The case for antiparticles in the extragalactic cosmic radiation

F. W. Stecker

Laboratory for High Energy Astrophysics, NASA–Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

A. W. Wolfendale

Department of Physics, University of Durham, Durham DH1 3LE, UK

The presence of an excess of low-energy antiprotons in the primary cosmic radiation[1–3] has given rise to several possible explanations[4], some of which involve exotic processes such as mini-black holes and extragalactic antiparticles. Here we consider the latter possibility[5] and show that there are interesting implications for the cosmic radiation at higher energies. Indeed, it may be possible to account for a previously puzzling feature of the cosmic ray spectrum—a 'bump' in the range 10^{14}–10^{15} eV—by hypothesizing a primary extragalactic origin for the bulk of the observed cosmic ray antiprotons, although such an explanation is not unique. In this model most of the cosmic rays above 10^{15} eV are extragalactic. We prescribe a method of testing this hypothesis experimentally.

One of the most fundamental questions in cosmology is the question of the existence of antimatter in significant quantities in the Universe. Does antimatter have an equal role with matter in the makeup of the galaxies? This question has now become one of fundamental importance to physics also. In the contemporary paradigm of grand unified gauge theories it is related to the question of the nature of charge parity violation at high energies[6]. Early attempts at constructing a baryon symmetric cosmology[7,8] suffered from the difficulty of providing an effective mechanism for separating matter and antimatter on ultimately large enough scales to be consistent with astronomical observations. However, recent theoretical work based on the concepts of grand unified theories (GUTs) has led to the development of a plausible baryon–antibaryon domain theory in which matter and antimatter are created in separate regions of survivable size to begin with (refs 9–11 and A. Mohanty, in preparation). Various observational aspects of this theory have been discussed previously[12,13] and the subject of baryon symmetric cosmology has been reviewed recently[14,15]. It should, of course, be noted that regardless of the ultimate fate of our present theoretical ideas either in favour of or against the reality of baryon symmetry on an overall universal scale, the experimental search for primary cosmologically significant quantities of antimatter is a task of deep significance. Further, both the recent theoretical work and the reports by various groups of surprisingly large fluxes of antiprotons in the cosmic radiation give immediacy to this search.

The present status of cosmic ray antiproton ($\bar{p}$) measurements and the attempts to understand them have been recently reviewed[4] and an exegesis of the primary extragalactic origin hypothesis has also been given recently[5]. Here we will discuss further implications of potential basic importance to cosmic ray research and we will propose an experimental search programme based on these considerations. We start with the hypothesis that the baryon symmetric domain cosmology leads to a flux of extragalactic cosmic rays consisting of roughly equal amounts of protons and antiprotons with the sources of these cosmic rays being primarily active galaxies[16,17] and with helium and antihelium nuclei being suppressed by destruction processes in these sources[5]. (We will also assume that helium and antihelium nuclei exist in the extragalactic cosmic rays at a lower level, supplied by leakage from normal matter galaxies and normal antimatter galaxies.) We further assume that the galactic wind is too weak to keep out the extragalactic cosmic radiation. Observations favour the interpretation that the galactic wind is in reality a 'breeze'[18].

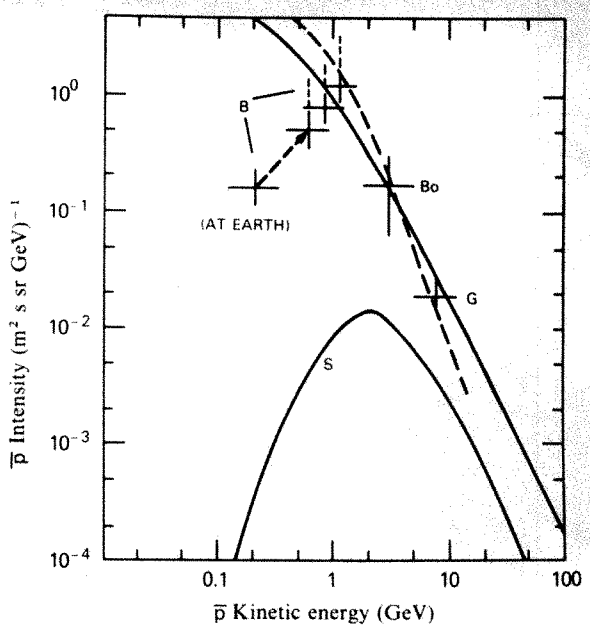

Fig. 1 Observations and theoretical $\bar{p}$ spectra. The data points are: B, from Buffington *et al.*[3]; Bo, from Bogomolov *et al.*[2]; and G, from Golden *et al.*[1]. The higher points marked B take account of solar modulation effects[24]. The solid curve (S) is for the secondary $\bar{p}$ production model with mean propagation length 5 g cm^{-2}, and the dashed line corresponds to the shape of the $\bar{p}$ spectrum calculated for a primordial black hole model[24]. The higher solid line corresponds to our spectrum for the extragalactic primary hypothesis as discussed in the text.

Let us first consider the energy spectrum of the cosmic radiation. The measured spectrum of cosmic radiation can be represented by a power law in energy of the form $KE^{-\Gamma}$ with the spectral index $\Gamma \simeq 2.75$ for several decades above the 10 GeV energy level. It seems likely that this radiation is produced primarily in galactic sources[19,20]. Furthermore, the source spectrum of this radiation is expected to have a lower spectral index, Γ_s, than that observed at the Earth which has been steepened by energy-dependent propagation effects. A value for Γ_s of ~2.0 to 2.2 appears to be likely for two reasons. (1) Measurements of the ratio of secondary to primary nuclei in the cosmic radiation suggest that the mean lifetime in the Galaxy due to trapping by the tangled galactic magnetic fields falls with energy as $E^{-\delta}$ where the most recently derived value[21] of δ is about 0.7. (2) The theoretical shock acceleration models for cosmic ray production that are presently favoured[22] generally yield production spectra with Γ_s close to 2.

If we assume that there exists a general acceleration mechanism for generating cosmic rays which acts in both galactic and extragalactic sources to give a universal source spectrum with $\Gamma_s \simeq 2$, as is now thought to be the case with shock acceleration, the extragalactic cosmic ray component should reflect this source

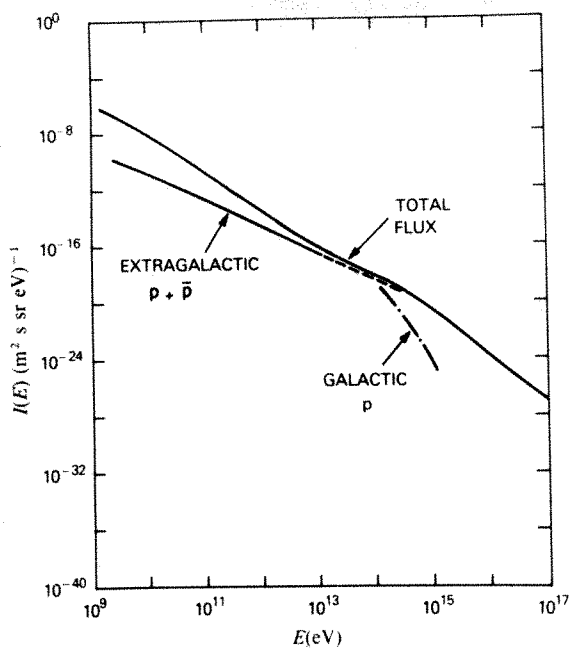

Fig. 2 The effect of extragalactic primary protons and antiprotons on the total cosmic ray spectrum according to the model discussed in the text. It can be seen that this model may account for the putative flattening in the observed cosmic ray spectrum near 10^{14} eV. $I(E)$ is the particle intensity, in the units shown.

spectrum. Thus, with the antiprotons assumed to be both primary and extragalactic and the bulk of the protons assumed to be galactic, the expected ratio of antiprotons to protons should increase with energy as E^{δ}. Taking $\delta \simeq 0.7$, antiprotons could make up approximately 1% of the cosmic ray flux at an energy of $\simeq 500$ GeV and even $\sim 50\%$ at higher energies; this has important observational implications which we will discuss later. Figure 1 shows the present data on antiproton intensities and a theoretical extrapolation corresponding to a primary extragalactic antiproton flux with $\Gamma = 2.0$. For these considerations, we assume that secondary production of antiprotons is unimportant (see, for example, the estimate given in Fig. 1).

Figure 2 shows the effect of extrapolating the extragalactic intensity of both protons and antiprotons (this introduces a factor of two) with a spectral index of 2 to higher energies and superposing it on the galactic cosmic ray spectrum with index $\Gamma \simeq 2.75$. Note that such an extrapolation implies that the extragalactic and galactic cosmic ray fluxes become comparable at an energy of $\sim 10^5$ GeV and that extragalactic particles predominate above this level. It is interesting to note that the resultant flattening in the spectrum occurs at this particular energy (10^5 GeV) where there have been claims[23] of a flattening in the cosmic ray spectrum as inferred from measurements of extensive air showers. It should, of course, be noted that a steepening in the spectra of both the galactic and extragalactic components would be required by the observations for energies above 10^6 GeV but this is not difficult to explain.

As our model indicates that the antiproton-to-proton ratio should increase with energy, measurements of the sign of the charges of cosmic rays at the highest practical energy and the determination of the spectra of the various charged components of the cosmic radiation up to that energy will provide a test of our hypothesis. Such a test requires that the experiment be placed above the atmosphere so that the incoming cosmic ray nuclei can be measured directly. Furthermore, the sign of the charged particles (and their magnitude) may be measured by using a superconducting magnet. Such an experiment, with an attainable energy of ~500–1,000 GeV, could be flown aboard a space shuttle (T. Bowen *et al.*, unpublished NASA research proposal). In addition, an emulsion stack experiment could be flown on a high-altitude balloon or on the space shuttle to look for antihelium nuclei, even at the reduced level implied by our hypothesis. A polar or near-polar orbit would be desirable to avoid the geomagnetic cutoff. In view of the almost impossible odds of creating a secondary ^{4}He antinucleus, the unambiguous detection of even one such particle would provide irrefutable evidence of primary cosmic ray antimatter. (It should be noted also that the production of 100–300 MeV antiprotons is extremely difficult because of well known kinematical factors[5]. This feat has proved elusive even to accelerator physicists who have deliberately set out in the laboratory to make such particles (C. Rubbia, personal communication). Thus, the observed low-energy antiprotons in the cosmic radiation are also quite difficult to explain as secondaries from cosmic-ray interactions.)

The experimental programme proposed above should add to our basic understanding of $\bar{p}$ origin. If the $\bar{p}/p$ ratio is observed to increase as $\sim E^{0.7}$, our hypothesis of extragalactic antiprotons from antimatter galaxies will receive strong support. The observation of antihelium nuclei would be conclusive. The extent to which non-observation of antihelium disproves our hypothesis is unclear, but if $\bar{\alpha}/\alpha \ll 10^{-5}$ (the value expected very approximately on the basis of $\bar{\alpha}$s leaking from 'normal' antimatter galaxies), the difficulty would be severe.

Non-observation of antihelium (at the level given above), together with an increase in the $\bar{p}/p$ ratio with energy at a slower rate than E^{δ} (for example, $\propto E^{0.25}$ between 10 and 100 GeV), would be consistent with the closed galaxy model (or source trapping), although there are severe theoretical problems[5,24] with such a model.

Finally, the observation of a $\bar{p}/p$ ratio falling rapidly with increasing energy would support the black hole model of Kiraly *et al.*[24] (see Fig. 1).

We thank Dr Jonathan Ormes for helpful discussions.

Neutrino tomography: Tevatron mapping versus the neutrino sky

Thomas L. Wilson

National Aeronautics and Space Administration, Lyndon B. Johnson Space Center, Houston, Texas 77058, USA

Volkova and Zatsepin[1] were the first to propose the use of a 'Tevatron' (a high-energy accelerator at 10^{12} eV or TeV energies) to beam neutrinos ν through the Earth to a mobile detector and obtain X rays of the planet's interior. The basic idea has been contingent for years on the opacity of the Earth to neutrinos at appropriate energies (10–10^3 TeV). This depends significantly on the neutrino–nucleon scattering cross-section, which in turn depends on the existence of an intermedi-

ate vector boson[2–4], the acceptance of what physicists refer to as the standard model[5–7] in high-energy physics, and finally the mass M_W of the intermediate W boson in that model. The announcement by CERN of the W boson mass[8,9] ($M_W \sim$ 80 GeV) permits us now to draw certain conclusions. Although we shall demonstrate that neutrino tomography at planetary densities is feasible, tomographic scanning schemes appear unrealistic in several respects. We shall address two sources of neutrinos for tomographic mapping of the densities, the Earth-based Tevatron and the neutrino sky.

Based on arguments from computerized tomography[10–13], group discussions[14] of future elementary particle facilities[15] (also in presentations of satellite tomography, Fig. 1) pointed out that 'X-raying' the Earth with neutrinos cannot provide a proper solution to its composition and density for the same reasons that single-projection X rays do not constitute an adequate reconstruction for noninvasive imaging in medicine. Geophysical densities follow from the mapping of the Radon or Fourier transform of certain neutrino projections, and not from the Volkova–Zatsepin scheme, as we shall demonstrate.

Tomographic mapping of the Earth is illustrated in Fig. 1, using deep underwater muon and neutrino detectors[16–18] (DUMAND). It measures a known distribution of ν radiation passing through an object, defining this as a projection χ, and taking the Fourier transform $F(u, v)$ of the projection over the two-dimensional Fourier space (u, v). The inverse transform determines the densities. It has been described in detail[12,13,19–21] and, in fact, is directly related to the very long baseline interferometry techniques used in radio astronomy[21–23]. Two source distributions are depicted: a parallel-beam projection generating a planar slice of data F_i through $F(u, v)$ (Fig. 1*a*, *b*), and a fan-beam projection in Fig. 1*c*, *d* generating a cylindrical slice $\tilde{F}_i$ of data on $F(u, v)$. Many multiple projections are required to map or 'fill in' the surface $F(u, v)$. in Fig. 1*b*.

Treated mathematically, the mapping problem was first addressed by Radon[24] who derived what has now become known as the Radon transform. Tomography[10,19,20,25] can be defined as reconstructive imaging by means of the inverse Radon transform technique, its relation to the Fourier transform having been extensively discussed[19,20,26–29]. Whenever the Radon or Fourier transform is inadequately determined, its inverse cannot be properly defined and the scheme is described as a mathematically ill-posed inverse transform problem[20].

The Volkova–Zatsepin Tevatron scheme, also proposed[30,31], is illustrated in Fig. 1*c*, which shows that an infinite number of fan-beam measurements using an infinite number of detectors or detector positions only maps one cylindrical slice $\tilde{F}_1$ of the Fourier transform for the Earth-fixed Tevatron A. We conclude from Fig. 1 that the geographically fixed Tevatron scheme of Volkova–Zatsepin, and its detector counterpart in Fig. 1*d*, constitute ill-posed inverse Radon transform problems, and therefore do not work[1,31] except as X-raying schemes, which have limited use in geophysics because they do not determine the densities. (The mobility referred to in ref. 31 is for geophysical prospecting, not for solution of the inverse Radon transform problem.)

The well-posed inverse Radon transform problem may be realized as follows. The source distribution must be known and measurable, and the neutrino source and detector must both rotate relative to the Earth, mapping an appropriate part of $F(u, v)$. The dashed circle in the u–v plane of Fig. 1*c*, *d* can be visualized as a fan-beam 'bubble' in momentum space located beneath the Tevatron A in real space. As A moves geographically, the bubble rotates about the origin of Fourier space and maps $F(u, v)$. Well-posed mapping schemes can be improvised from Fig. 1.

Having a well-posed scheme, the opacity of the Earth must be estimated. It can be determined from seismic models of the Earth's density distribution. Standard models have been described by Press[32] and Dziewonski and Anderson[33], supplemented by extensive work on the geochemical composition of the Earth by others[34–37]. We adopt the Dziewonski–Anderson preliminary reference earth model (PREM) here primarily because it states explicitly the radial density functions ρ. It is compatible with the Monte Carlo study of Press[32]. The results are given in Table 1 and illustrated in Fig. 2. Figure 3*a* will be used in the derivation.

The PREM density distributions define zones or concentric shells[33]. Cords of path length L at angle ψ from the nadir were chosen tangent to each shell at a depth $d = a(1 - \sin\psi)$, where $a = 6{,}371$ km is the radius of the Earth. By means of a simple coordinate transformation, line integrals were then performed along L to determine the total nucleon mass $M = M(\psi)$ in a 1 cm^2 cylindrical column at angle ψ through the PREM model:

$$M(\psi) = \int \rho(\psi, L)\, \mathrm{d}L \qquad (1)$$

(ρ in equation (1) is actually measured in ν-tomography by the inverse Radon transform technique already described.) The total mass was next divided by the mean mass per nucleon $\bar{m}_n$ to

Table 1 Neutrino tomography, from the PREM Earth model

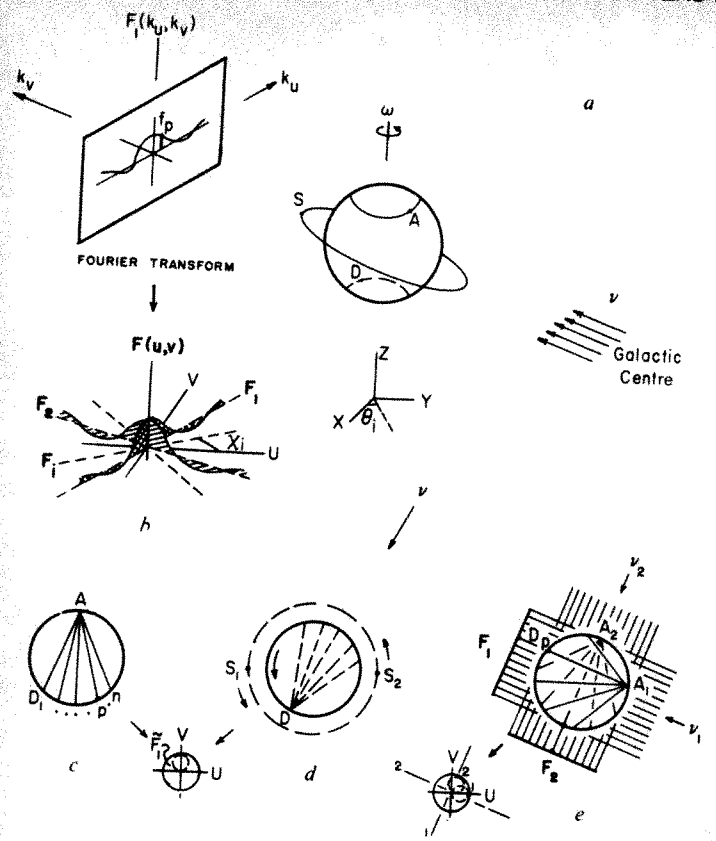

Fig. 1 Neutrino tomography represented as an idealized problem of mapping the Fourier transform $F(u, v)$ of projections of high-energy neutrinos ν through the Earth. *a*, With the Earth fixed ($\omega = 0$) in the inertial frame XYZ a ν-detector S orbiting in the galactic plane could generate one slice $F_i(u, v)$ of the transform in two-dimensional momentum space (k_u, k_v) of Fourier space (u, v). *b*, The actual Earth rotates in the inertial XYZ frame ($\omega \neq 0$) about the Z-axis shown, and for any Right Ascension θ_i, S would generate another slice F_i, gradually mapping $F(u, v)$. *c*, An Earth-fixed fan-beam scanning scheme is shown consisting of an accelerator A, beaming TeV neutrinos through the Earth to a mobile ν-detector D. *c* Is mathematically ill-posed; it can generate only one cylindrical slice $\tilde{F}_1$ of points on the surface $F(u, v)$, depicted by the dashed circle (a polar vector of magnitude $a \sin \psi$) in the u–v plane of *c*. *d*, Another ill-posed scheme using an Earth-fixed detector D which scans the Earth's interior while the Earth rotates about the celestial sphere. Schemes *c* and *d* pose acceptable imaging configurations only when A and D are moved. *e*, Part of a well-posed global ring of collaborative Tevatrons, or mobile positions. $\tilde{F}$ is constructed by knowing that $A_1D_p \rightarrow f_p$ is measured by the same fan or parallel beam. To visualize measuring the density of one point P* within the Earth, its contour of data on $F(u, v)$ is the smallest cylindrical slice $\tilde{F}^*$ (that is, a smaller dashed circle like that in *c*) osculating with P^* and the centre of the Earth. $\tilde{F}^*$ is measured by moving A on the surface and measuring values of $\tilde{F}$ in *c* where it intersects $\tilde{F}^*$ while $\tilde{F}$ rotates around the u–v origin.

derive the number of nucleons n in the column L. That is, $n = \bar{m}_n^{-1} M$ where $\bar{m}_n^{-1} = 6.029030 \times 10^{23}\ g^{-1}$ is approximately Avogadro's number N_A, and was derived from refs 38, 39 assuming an equal number of protons and neutrons, an average binding energy per mass number of 8.5 MeV and mass numbers of 24 for the mantle and 46 for the core[36,37].

Dividing the nucleon number n by the volume of the column which is $L\ cm^3$, we derive the nucleon density N averaged along the cord: $N = n/L\ cm^{-3}$. Given a neutrino–nucleon scattering cross-section $\sigma_{\nu N}$ (an area in cm^2), the neutrino's opacity κ_ν follows dimensionally as the product of $\sigma_{\nu N}$ and N:

$$\kappa_\nu = \sigma_{\nu N} N = \sigma_{\nu N}\, n/L \quad cm^{-1} \tag{2}$$

The neutrino's mean free path is simply the inverse of its opacity: $\lambda_\nu = \kappa_\nu^{-1}$ cm.

The issue of critical importance in equation (2) is the energy dependence of $\sigma_{\nu N}$. At energies below 1 TeV, experimental groups[38–41] have corroborated the assumption that $\sigma_{\nu N}$ increases linearly with neutrino energy E_ν,

$$\sigma_{\nu N} = 0.67 \times 10^{-38}\, E_\nu \quad cm^2 \tag{3}$$

where E_ν is in units of GeV $= 10^{-3}$ TeV. Equation (3) is known as the Bjorken scaling hypothesis[42,43]. It is shown graphically as the dashed straight line in Fig. 3*a*, and is predicted by the ordinary four-fermion theory of the weak interaction[44]. It is equivalent to the assumption that $M_W = \infty$, and was used in refs 1 and 31. However, a fundamental tenet of particle physics is that equation (3) cannot be valid at arbitrarily high energies, because it eventually violates what physicists refer to as the unitary of the scattering matrix[44,45]. It was shown[46] that the deep-inelastic cross-section levels off logarithmically at higher energies due to virtual W boson propagator effects (equation (6.4) of ref. 46),

$$\sigma_{\nu N} \sim \log E_\nu \tag{4}$$

instead of increasing linearly as in equation (3).

Theoretical studies of neutrino cross-sections have shown the Bjorken–Paschos effect in equation (4) to be prevalent at tomographic energies (10–10^4 TeV). Original concern was with the production of real W bosons[47–54] by elastic scattering from target nuclei[47–51] (coherent) or individual nucleons[48–51] (incoherent) at small values of the W boson mass ($M_W \sim 5$ GeV). As estimates for M_W increased ($M_W \sim 80$ GeV), the earlier results[49] were revised[52–54] for elastic W boson production while interest continued in the deep-inelastic case[41,52–55] where the target nucleon breaks up into hadronic debris X (for example, $\nu + N \rightarrow \mu + X$). It involved the production of virtual (not real) W bosons[41,51–54], and was shown[51–54] to be the dominant[52,53,55] effect at the energies considered here.

We adopt the values for $\sigma_{\nu N}$ as those stated by Halprin[53] using the quark–parton distributions of Buras and Gaemers[41,56] for $M_W = 80$ GeV as announced by CERN[8,9], with a Bjorken–Paschos logarithmic extension from equation (4). This is shown graphically in Fig. 3*a*, which is the basis for Figs 2 and 3. (Had M_W been much smaller, $\sigma_{\nu N}$ in Fig. 3*a* would level off as shown by the dotted curve at a value too low for ν-tomography to work for planetary densities.)

Tomography (Fig. 2) is concerned with the measurement of the transmitted intensity I of neutrinos as compared with the incident intensity I_0 (refs 10, 11). I_0 must be known. These are related to κ and λ by

$$I = I_0\, e^{-\kappa L} = I_0\, e^{-L/\lambda} \tag{5}$$

as a function of path length L through the Earth. The attenuation is $(1 - I/I_0)$ and is given in Fig. 2 as a percentage for 1, 10 and 100 TeV using the PREM values. The Earth is still virtually transparent at 1 TeV, tomography of the core is possible at 10 TeV and imaging out into the upper mantle is possible at 100 TeV, if we assume a minimum attenuation of 10% to account for measurement uncertainties. Surface tomography[31] below 100 TeV at PREM densities appears meaningless (except for very dense anomalies there) because the mean free path exceeds 5 Earth radii at that energy (Table 1).

Because tomography cannot be performed without a knowledge of the source distribution I_0, Tevatron tomography offers the distinct advantage that I_0 can be accurately measured and controlled. On the other hand, we have seen that the inverse Radon transform problem requires an unrealistic, global distribution of Tevatrons and DUMAND-type detectors. We now address the question posed by Fig. 1*d* of the existence of a tomographic sky, treating ν-tomography as a discipline of astronomy and requiring only the detectors. Neutrino tomography might be feasible as an analysis of the nadir data cuts, using I_0 determined from the zenith data cuts in neutrino astronomy.

Natural sources, predicted in the neutrino sky, are illustrated in Fig. 3, adapted from Margolis, Schramm and Silberberg[57,58]

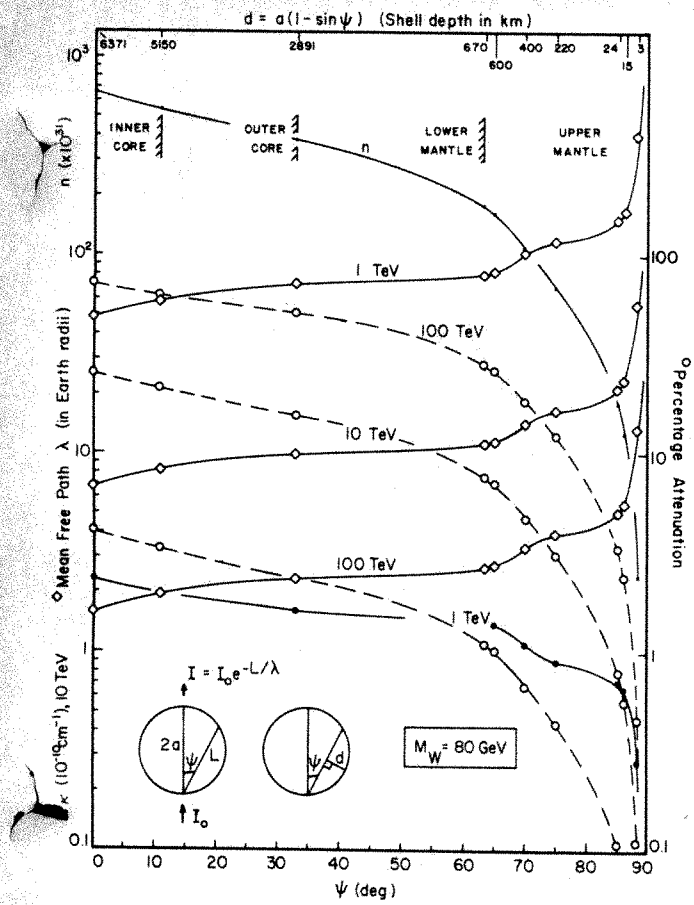

Fig. 2 Opacity of the Earth to neutrinos, derived from the PREM density model of ref. 33. The number of nucleons n in a cylindrical column 1 cm^2 in area along a cord of length L is plotted as a function of the angle ψ from the nadir. From n and L a neutrino opacity κ is derived as a function of neutrino cross-section (shown in Fig. 3a) and therefore energy. The mean free path of the neutrino $\lambda = \kappa^{-1}$ is shown by solid lines, and the corresponding percentage attenuation is given as the dashed lines at the same energies. Tomography 'works' when the attenuation exceeds some threshold value (assumed here as 10%, see ref. 18, p. 235) which accounts for measurement uncertainties. Neutrino oscillations[16–18] have been neglected. (An actual beam of neutrinos from an accelerator diverges, forming a conical frustrum whose volume is approximately $AL/3$, where A is the area of the ν-beam as it leaves the Earth; the number of nucleons n' in the beam's volume is $n' = An/3$. Although n' is $10^{10}/3$ times n for $L = 2a$ and $A = 1\ km^2$ using a π-meson source in ref. 1, mean nucleon density is unchanged. Tomographic resolution is sacrificed as n' increases for different ν-sources.)

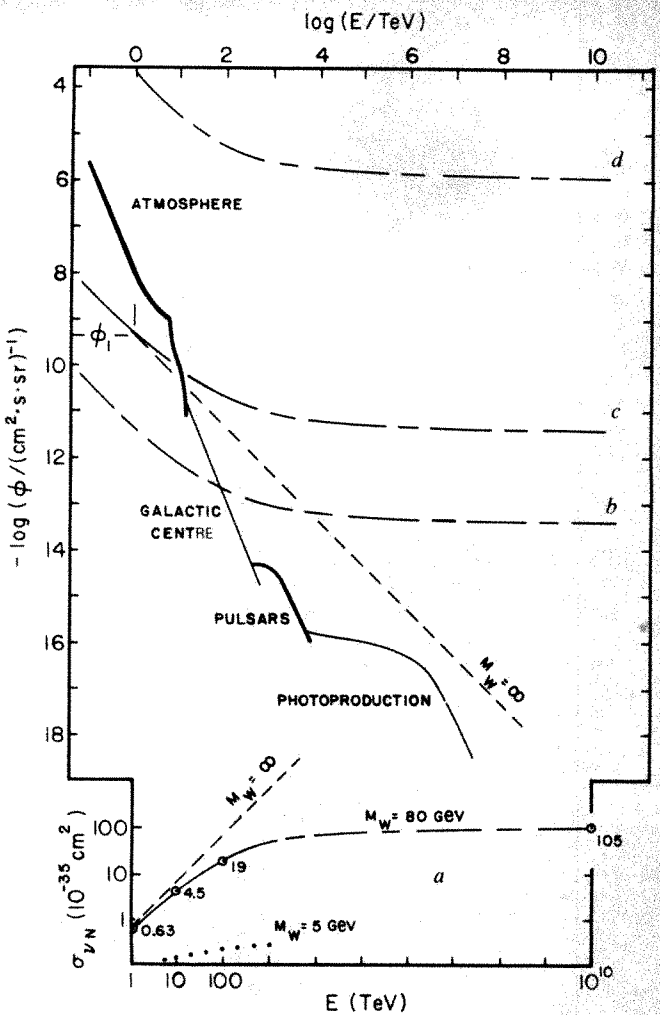

Fig. 3 Natural sources of neutrinos for reconstructive imaging of the Earth's interior density. The neutrino flux ϕ is shown by the solid curves as a function of TeV energy, first compiled in refs 57 and 59. The logarithmic energy scales are equivalent (the upper used in ν-astronomy and the lower in particle physics). The dashed curves are detectors. The flux ϕ_1 at 1 TeV for the 10^9 ton detector is 4.8×10^{-10} cm^{-2} s^{-1} sr^{-1}. Inset a shows the neutrino–nucleon cross-section $\sigma_{\nu N}$ as a function of TeV energy for $M_W = 80$ GeV, and is not a part of the flux diagram. The values indicated at 1, 10 and 100 TeV are taken from ref. 53, while those at 10^3 and 10^4 TeV (35 and 45, respectively) are not shown because the validity of the Buras–Gaemers[56] assumptions in that energy range and beyond is questionable. For $E_\nu > 10^3$ TeV, the curve is dashed to emphasize that it represents only an extension of the Bjorken–Paschos logarithmic term in the Buras–Gaemers–Halprin cross-section at 1, 10, 100 TeV, and is unknown beyond 10^4 TeV. b–d, Detectors capable of measuring 1 count per day and they follow from $\sigma_{\nu N}$ in a and ν-flux arguments given in refs 57–59. b Is 10^{11} tonnes and c is 10^9 tonnes, both of the type considered for DUMAND. d, The flux sensitivity of one orbiting Shuttle external tank (73 trips with 2,157 tonnes of water), as an illustration of the unrealistic effort required for ν-tomography from near-Earth orbit.

and Stecker[59]. The sensitivities of various detectors are derived for $M_W = 80$ GeV, which is essentially an inversion of $\sigma_{\nu N}$ in Fig. 3a to the appropriate flux ϕ. The flux for a 10^9 ton detector at 1 TeV, assuming $M_W = \infty$, is shown as ϕ_1 which calibrated our curve c (Fig. 3), and from which followed curves b and d. We can see from Fig. 3 that a 10^{11} ton DUMAND detector can feasibly measure 100 TeV tomographic neutrinos from the (distended) galactic centre. It seems less probable that a 10^9 ton detector (which measures down to 10 TeV) could differentiate these galactic centre neutrinos from atmospheric, co-rotating neutrinos originating on the opposite side of the Earth and passing through it. (Neutrinos from co-rotating sources, such as the atmosphere and from cosmic rays colliding with the interior, can conceivably be cut from the data using tomographic arguments.) Any other, as yet undiscovered, point source of tomographic neutrinos in the neutrino sky (such as the supernova remnant Cas A or the radio galaxy Cen A, discussed in ref. 57) whose flux lies above the DUMAND detector sensitivity threshold in Fig. 3, might function as well for the 72% core attenuation given in Fig. 2 at 100 TeV.

The flux in Fig. 3 is extremely low (1 event per day), and may be inaccurate by magnitudes. Unless an intense source were discovered in the neutrino sky, the galactic centre represents a varying source I_0 at low flux which means the data (for whole-Earth tomography) must be taken over considerable periods of time. It is feasible but unrealistic.

In conclusion, well-posed mapping schemes require impractical distributions of Tevatrons and neutrino detectors, or detectors over unrealistic periods of time. Whole-Earth tomography

seems out of the question (Fig. 2), requiring inordinate energies (>100 TeV) whose neutrino physics is little understood, although the non-invasive measurement of the density at one or more points in the core is less remote. The true significance of neutrino tomography probably lies not in its implementation but in the importance of where it focuses interdisciplinary attention in geophysics[33] and physics[47–55]: the neutrino cross-sections[47–55] (coherent and incoherent) for constituent substances[33–37] at tomographic energies (10–10^4 TeV), although the neutrinos appear insensitive[55,52] to the coherent nuclei at these energies (as was assumed here). The density at one point in the core or lower mantle is determinable, and such a study is feasible but impractical by this analysis.

I thank the late Professor Salomon Bochner for several conversations regarding the inverse Radon transform and Bochner's own contribution to ref. 25. I also thank A. M. Jaffe, I. P. Nedialkov, I. Duck and R. F. Guertin; A. A. Jackson IV for reviewing the manuscript; and R. W. Brown and A. Halprin for discussing their work on the neutrino cross-sections.

Molecular conformations in surfactant micelles

Ken A. Dill*, Daniel E. Koppel*, Robert S. Cantor*, James D. Dill†, Dalila Bendedouch‡ & Sow-Hsin Chen‡

For more than half a century, the cornerstone to our understanding of molecular organization in amphiphilic aggregates has been Langmuir's principle of differential solubility[1], according to which the polar heads of amphiphilic molecules dissolve in water whereas the hydrocarbon tails cluster in a core in order to minimize solvent contact[2–5]. This view has recently been challenged; much spectroscopic data[6–17] have been construed[11–17] to indicate significant penetration of water into the cores of micelles. Here various models of micellar structure are critically tested against results from NMR and recent small-angle neutron scattering (SANS) experiments. Molecular organization is found to be the consequence of Langmuir's principle and of the packing requirements imposed by steric constraints among chain molecules at interfaces. The evidence is unambiguous that these cores are virtually devoid of internal water.

SANS experiments[18] were performed on micelles consisting of terminally-deuterated lithium dodecyl sulphate molecules (3.672×10^{-2} M) in 0.3 M LiCl solution in D_2O at 35 °C. The advantages of these conditions for the present purposes are that the micelles are nearly spherical and monodisperse[18–20]. The intensity, $I_D(q)$, of elastically scattered neutrons was measured as a function of wave vector $q=(4\pi/\lambda)\sin(\theta/2)$, where θ is the scattering angle and λ (=4.75 or 5.00 Å) is the wavelength of the neutrons. Parallel experiments were performed on protonated micelles, from which $I_H(q)$ was obtained. The scattering intensity is approximately separable into factors $P(q)$, representing intramicellar structure, of interest here, and $S(q)$, representing the positional correlations of particles in solution; that is, $I(q)=mP(q)S(q)$ where m is the number density of micelles[20]. The difference amplitude, $A(q)$, of the scattering from the chain termini can be calculated from the measured intensities by

$$A(q)=\{[I_H(q)]^{1/2}-[I_D(q)]^{1/2}\}[S(q)]^{-1/2} \qquad (1)$$

the procedure for calculating $S(q)$ is presented elsewhere[18–20]. Values for $A(q)$ thus obtained from our experiments are shown in Fig. 1. The radial density distribution, $N_{Me}(r)$, of termini per unit volume throughout the micellar core can be derived from $A(q)$ (ref. 18)

$$A(q)=m^{1/2}\int_0^\infty 4\pi r^2 b_{Me}N_{Me}(r)\left(\frac{\sin qr}{qr}\right)dr \qquad (2)$$

where $b_{Me}=|b_{CH3}-b_{CD3}|=3.12\times10^{-12}$ cm is the difference in scattering lengths.

Various models of micellar core structure predict different radial density distributions, $N_{Me}(r)$, of the termini therein. Evaluation of equation (2) according to each model described below yields the set of scattering functions $A(q)$ shown in Fig. 1. To calculate these distributions, it is convenient to consider the hydrocarbon core as being partitioned into discrete concentric shells, numbered $i=1,2,3\ldots,n+1$, towards the centre. Chains are assumed to have $n+1$ segments. The ith shell contains $N_i=(4\pi/3)[3(n+2-i)(n+1-i)+1]$ equivolume sites. Each site contains at most one chain segment. For chain lengths to be independent of configuration, sites must be approximately isodiametric[21,22]; dodecyl chains are thus most suitably

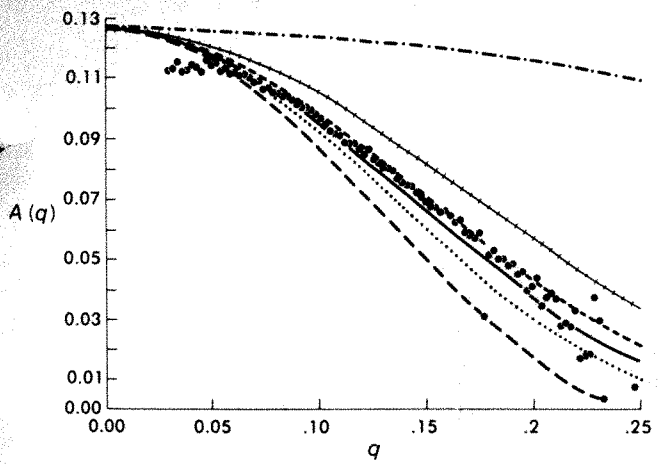

Fig. 1 Small-angle neutron scattering amplitudes, $A(q)$ against wavevector, q. Data from ref. 18, corrected here for interparticle interactions according to equation (1). Predictions (radial shells are numbered $i = 1, 2, 3, 4$, towards the micellar centre) are given by: (1) Radial chain model; $t_i = 0, 0, 0, 1$ (—·—). (2) Pincushion model; $t_i = 0, 0.563, 0.375, 0.062$ (++++). (3) Interphase model, $\omega = 1$; $t_i = 0.234, 0.414, 0.289, 0.062$ (– – –). (4) Interphase model, $\omega = 0.5$; $t_i = 0.326, 0.370, 0.241, 0.062$ (——). (5) Interphase model, $\omega \to 0$ (identical to Cabane model[25]); $t_i = 0.438, 0.312, 0.188, 0.062$ (· · · · ·). (6) Oil droplet model; $t_i = 0.578, 0.297, 0.109, 0.016$ (— —).

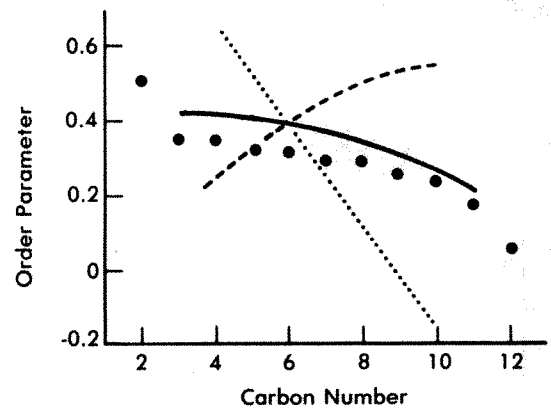

Fig. 2 ^{2}H-NMR disorder gradient measurements of potassium laurate micelles in the hexagonal phase against chain position from the head group. Data from ref. 27 are multipled by 2 to correspond to the bond order parameter defined according to the interphase theory[22,31]: – – –, freely flexible chains, $\omega = 1$; ——, 'real' chains, $\omega = 0.5$; · · · · · rigid molecules, $\omega \to 0$. The oil droplet model predicts $S = 0$ and the radial chain model $S = 1$ for all segments.

represented by $n+1 \cong 4$. The end group density may be expressed as $N_{Me}(r) = (J_1/N_i) \cdot [(n+1)/R]^3 \cdot t_i$, where t_i is the fraction of chains whose termini are in layer i, $J_1 = 82$ is the number of chains per micelle, and $R = 18.9$ Å is the equivalent spherical radius of the micellar core[19].

The following models are considered: (1) The radial chain model. Micellar chains are often depicted as radially aligned and largely all-*trans*[23,24]. Taken literally, this model would require all termini to occupy the same element of volume at the core centre, in violation of volume exclusion constraints. That this model, which represents the maximum possible radial order and porosity of the core to solvent, is not viable is evident from comparison with the SANS and other results (see Fig. 1 and refs 25, 26).

(2) The pincushion model[11] admits of lesser—but significant—water penetration into outer regions of the core. For purposes of calculation, we adopt a version of this model according to which chain ends are distributed as close to the core centre as is consistent with packing constraints. The core centre contains only termini. Sites in the surrounding shell are occupied by the few radially-aligned bonds required to connect to the centre termini and are otherwise filled by chain termini: this shell contains no lateral bonds (that is, those normal to the radius). The next (third) shell is similarly occupied by forward steps to central layers and by the remaining termini. This and surrounding shells may be further occupied by any distribution of lateral and forward segments and solvent molecules with no further bearing on the distribution of termini. Thus, this model represents a class of configurations with water penetration of 20–60% of the outer layers of the core. This model is also in poor accord with the SANS data (Fig. 1).

(3) In the oil droplet model[3], the micellar core resembles pure, amorphous, liquid alkane. Accordingly, chain ends are distributed uniformly throughout the core, the number in each shell being proportional to its volume. This model overestimates the methyl density at the solvent interface (see Fig. 1 and ref. 18). Other evidence shows that the chains in micellar cores are more ordered than in liquid alkanes[1,3,25–30].

(4) According to the interphase model[21,22,31,32], the core is filled exclusively by chain segments which are randomly distributed except as required to preserve chain continuity and satisfy excluded volume constraints. These requirements are taken into account through application of a matrix method[21,22,31]. The first chain segments connected to head groups are required to occupy the outermost shell of the core; the remaining sites of that shell are filled by laterally bonded segments. Other layers are similarly occupied by bonds which enter shell i from $i-1$, or by lateral bonds in i. Subject to these constraints, chain segment orientation is otherwise random, for freely flexible chains[21,22]. Real chains are not freely flexible, however. Their stiffness may be taken approximately into account through a statistical weight ω, representing the *a priori* probability of a 'bent' bond pair relative to a co-linear pair in an isolated molecule[31,32]. With this refinement, freely flexible chains are represented by $\omega = 1$, rigid molecules by $\omega \to 0$ and real polymethylene chains at $T = 300$ K approximately by $0.4 \leq \omega \leq 0.5$; predictions for these three cases are shown in Fig. 1. Since the interphase model requires complete filling of the core volume, then even for $\omega \to 0$, most chains are required to have one bend; in this limit, the chain configurations are identical to those predicted by the simple micellar packing model of Cabane[25].

The results of the interphase model have been mimicked through an alternative formulation[33,34] in which intramolecular interactions are treated in the rotational isomeric state approximation[35], but in which steric packing constraints are represented through internal pressures which differ in each shell. The latter premise is unsatisfactory inasmuch as the requirement for mechanical equilibrium is thereby violated; these pressures are introduced to simulate packing constraints. The constraints are modelled explicitly, however, by the interphase treatment described above.

Interphase theory predictions are in good agreement with experimental measurements of configurational properties of amphiphilic aggregates[1,21,22,26,32,36]. We have previously noted that one prediction, however, has been in disagreement with experiment[1]; here that issue is resolved. The interphase theory for freely flexible chains predicts that the order should increase towards the chain ends in micelles (see the dashed curve in Fig. 2; see also ref. 22). ^{2}H-NMR experiments with perdeuterated chains in hexagonal phase micelles[27] show the reverse, that there is increasing orientational disorder towards the terminal groups. This closely resembles the 'disorder gradient' in bilayer membranes[21,37]. Recent refinement of interphase theory[31,32] shows that orientational order in micelles depends markedly on chain stiffness, neglected in the earlier approximation[22] (compare the solid curve in Fig. 2). Intramolecular interactions thus contribute significantly to micellar chain organization whereas for planar bilayers the disorder gradient depends primarily on intermolecular constraints[32].

There is broad support for the view that water is largely excluded from the interior of micellar hydrocarbon cores (refs 1, 3, 4, 18, 25 and references therein). This conclusion is corrob-

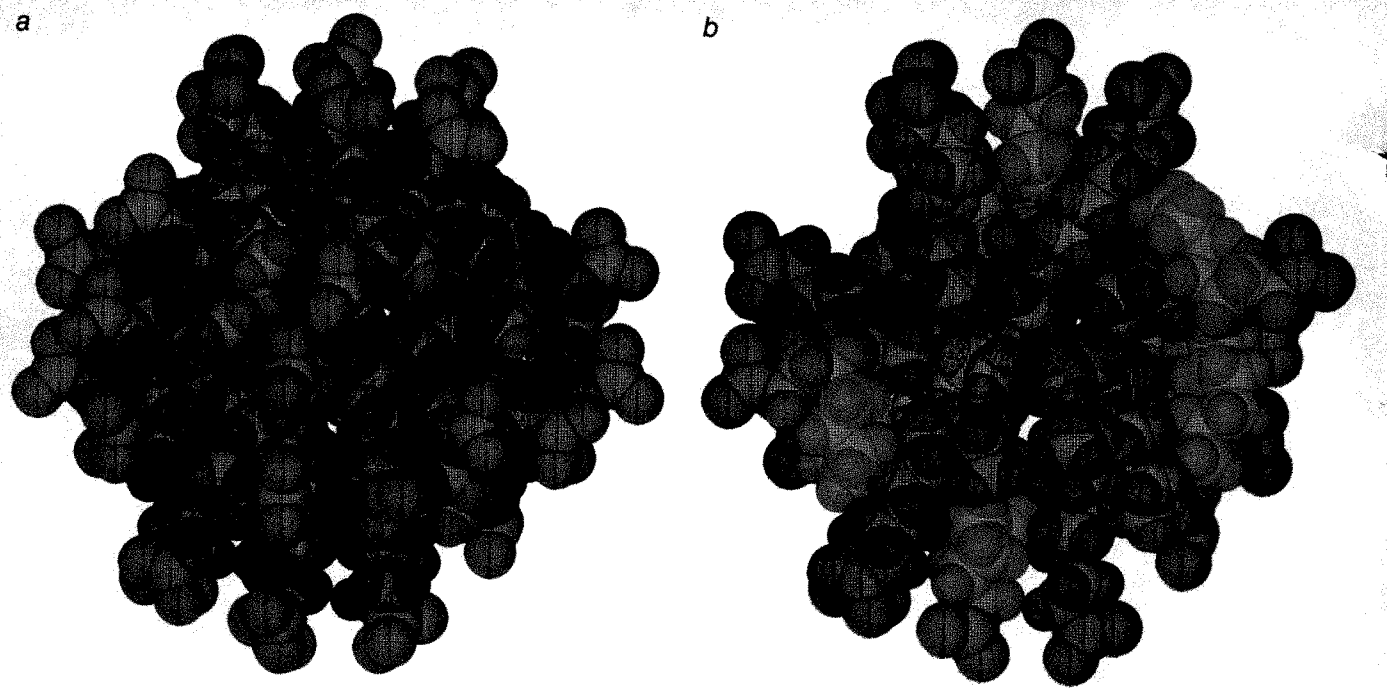

Fig. 3 Representative configuration of a 38-chain spherical decanoate micelle according to the interphase theory[22,31]. Computer graphics were performed with a modified version of SPACFIL at Molecular Design, Ltd. The micelle was constructed by configuring chains on a spherical lattice, then applying a nonlinear least-squares method to best fit vectors, representing C–C bonds between methylenes, through the appropriate lattice sites. *a*, Outside surface. Head groups in green, methylenes in black and terminal methyls in red. Much hydrocarbon, including some chain ends, is exposed to solvent. *b*, Micellar interior; front hemisphere removed. Red molecules terminate near the surface, blue ones midway to the centre and black ones at the core centre. In this view, chain disorder, distribution of termini and density of packing are evident.

orated by the results of Fig. 1 showing that the differential SANS data are best modelled by dry hydrocarbon core configurations. The strongest support for this view, however, comes fron SANS contrast variation measurements of absolute scattering length density[18,38]. In a series of independent measurements[18], lithium dodecyl sulphate micelles with mean aggregation number of 78 were shown to have a hydrocarbon core volume per molecule ($28{,}085/78 = 360$ Å^3) equal to that of a pure dodecyl chain[3]. Moreover, the measured scattering length density of the core ($\rho = -3.8\times10^{-7}$ Å^{-2}) is exactly equal to that predicted for a dry core consisting exclusively of dodecyl chains ($b_{C12} = -1.37\times10^{-12}$ cm; thus $\rho = -1.37\times10^{-4}$ Å$/360$ Å$^3 = -3.8\times10^{-7}$ Å^{-2}). These experiments could have readily detected one D_2O molecule per amphiphile in the core. X-ray diffraction experiments[39] are more equivocal because they only provide relative densities. The preponderance of support for the alternative view[11–17], that there is water penetration, has come from spectroscopic experiments, in which water-insoluble probes in micellar solution have been found to reside in a partly aqueous environment[6–17,40,41]. The two alternative interpretations of these data are that the probes and water may associate either in the core or at the interface. Recent ring-current shift NMR measurements show that many of these probes reside at the interface[40–42]. ^{19}F-NMR spectroscopy on perfluorooctanoate micelles shows that the segments of the micellar chains similarly reside in a partly aqueous environment[43]. This result should not be surprising, however, for nearly 60% of the chain segments in small micelles are at the surface[1]. Recent interphase theory calculations predict quantitatively the degree of water contact of each of the chain segments as measured in the ^{19}F-NMR experiments[1]; it is the consequence of the high equilibrium incidence of chain segments at the core interface. We conclude that micellar hydrocarbon cores are virtually devoid of internal water, but that substantial hydrocarbon/water contact occurs at the core interface.

Computer graphics representations of the interphase model (Fig. 3*a*, *b*) show the degree of chain disorder, the distribution of termini and the extent to which hydrocarbon segments, including chain ends, are exposed to the solvent at the core interface.

The structures and properties of micellar aggregates are thus found to be the consequences of: (1) Langmuir's principle of differential solubility, according to which hydrocarbons are sequestered into a core devoid of water surrounded by the polar heads; (2) the principle that steric forces predominantly determine the structures of condensed phases[44]; and (3) the statistical mechanical principle that degrees of freedom of equal energy (in this case, of the intramolecular chain configurations) are of equal likelihood.

We thank the NIGMS, NSF and ACS Petroleum Research Fund for support.

Note added in proof: In a recent study[45], it is claimed that micellar chains form 'loops', with termini 200 times more exposed to solvent than internal segments. Those results have no bearing on unperturbed micelles, however, for the SANS results presented here would have detected even a small degree of looping, and showed none. In that study, termini and internal groups were double bonds on probe molecules of significantly different lengths. Neither the locations of those molecules nor their double bonds with respect to any micelles present were known. Double bonds are attracted to water[3] and chains of different lengths prefer different phases; few extrinsic probes of micelles are innocuous[1,4].

Synchrotron X-ray diffraction from a 800 μm^3 zeolite microcrystal

P. Eisenberger, J. M. Newsam, M. E. Leonowicz & D. E. W. Vaughan

Exxon Research and Engineering Co., Route 22 East, Annandale, New Jersey 08801, USA

The brightness of synchrotron X-ray sources, which exceeds that available from conventional generators by many orders of magnitude[1–3], provides the possibility of making conventional measurements on much smaller samples. We describe here measurements of Bragg diffracted intensities from two microcrystals of cancrinite, a typical zeolite, performed in order to assess the scope of microcrystal diffraction. Our results demonstrate that many materials previously regarded as polycrystalline can now be studied using well established single-crystal methods at synchrotron facilities.

Crystals of basic/nitrate cancrinite[4–7] were selected from a hydrothermal crystallization batch (F. W. Webster and E. A. D. White, unpublished) that contained specimens ranging in size from several micrometres up to millimetres. Cancrinite is a typical zeolite with an open structure built of atoms of low atomic number [actual composition in this case $Na_6Al_6Si_6O_{24}$. $0.33(NaNO_3)$. $1.22(NaOH)$. $2.2(H_2O)$] and with some structural imperfection. It therefore provides a near 'worst case' test. One of the larger crystals from the batch had been measured on a conventional CAD-4F diffractometer[8], enabling us to make a direct correlation between measured intensities and structure factors of known magnitude. The cancrinite structure has hexagonal symmetry and the crystals generally had needle-like morphologies, the long direction coinciding with the unique crystallographic axis. This elongate characteristic allowed the 001 direction to be defined visually in an optical microscope, the selected crystals being too small to align by conventional X-ray photographic techniques. Two crystals of approximate dimensions $35 \times 25 \times 25$ μm (no. 1) and $20 \times 10 \times 4$ μm (no. 2) (dimensions estimated by reference to a 12.5-μm eyepiece scale) were selected, glued to the ends of Pyrex glass fibres of ~10 μm outside diameter, cut to 1 cm long, mounted on eucentric goniometer arcs and aligned so as to rotate about a direction perpendicular to the long axis.

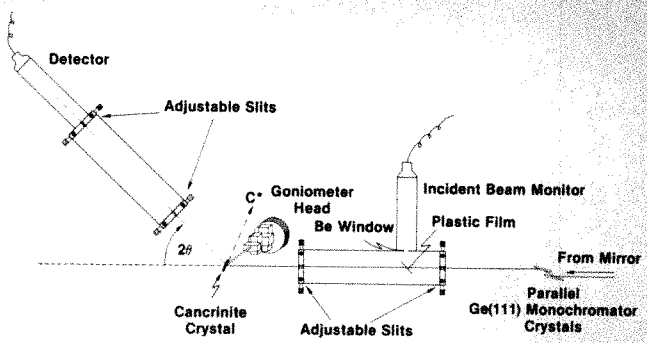

Fig. 1 Schematic diagram of the experimental arrangement. The evacuated boxes housing the adjustable slits and the beam monitor arrangement are shown. Because of the beam polarization, the scattering plane is vertical and the crystal orientation was chosen such that the c^* axis would lie in this plane at $\chi \approx 0°$ (as indicated).

Measurements were made on the 4-circle Huber diffractometer located at the VII-2 Wiggler line at the Stanford Synchrotron Radiation Laboratory, Stanford[9], during the tune-up period after the summer shutdown, so that the beam condition was rather poor (see below). On the VII-2 beam line, 4.6 mrad of arc can be viewed by the mirror which focuses the beam at the sample position. After the mirror, a mean incident wavelength of 1.74 Å was selected from a pair of parallel, asymmetrically cut Ge(111) crystals. Both incident and diffracted beams were collimated by evacuated adjustable slit systems (Fig. 1). The arcs with the cancrinite crystals were mounted directly onto the diffractometer, the only adjustment made being that of sample height. No particular precautions were taken to minimize the background.

At the chosen wavelength, we had access to two significant $00l$ reflections, $l = 2$ and $l = 4$. The configuration was chosen so that the c^* axis would lie in the scattering (vertical) plane (Fig. 1). The crystals were rotated about the spindle axis with the detector set at the 002 position until significant intensity was observed in the counter meter. The reflections were then centred incrementally in each of the circles. In both cases, only minor adjustment of the χ-circle was necessary, demonstrating the effectiveness of the initial optical alignment procedure. Table 1 summarizes the data obtained in radial and rocking-curve scans of the crystals, while scans of the smaller crystal are plotted in Fig. 2. For the larger crystal (no. 1), we also made a scan along $00l$ from $l = 1.990$ to 3.015 which indicated that both satellites and the 003 reflection have structure factors of less than 0.9 electrons.

The total energy, E, reflected by a crystal volume δV as it is rotated through the region of a Bragg reflection hkl is (see, for example, ref. 10)

$$E = I_0 \left(\frac{e^2}{4\pi\varepsilon_0 mc^2}\right)^2 \frac{\lambda^3}{V^2} \delta V |F_{hkl}|^2 \frac{1}{\sin 2\theta} \frac{1}{\omega}$$

We have used this expression to estimate I_0, the incident photon flux within the resolution element sampled, from the integrated intensities given in Table 1. The results are given in Table 2. Considering the poor beam conditions, the errors associated with estimating E (Table 2) and the crystal dimensions (as above), the agreement between the three independent estimates is reasonable.

The measured background levels were low. For example, at $h = 0$, $k = 0$, $l = 2.1$ (well away from the central Bragg point), the backgrounds were 2.4 (no. 1) and 0.7 (no. 2) counts s^{-1}, respectively. On the edge of the wings of the Bragg peaks, three halfwidths from the central point, the observed signals were 8.5

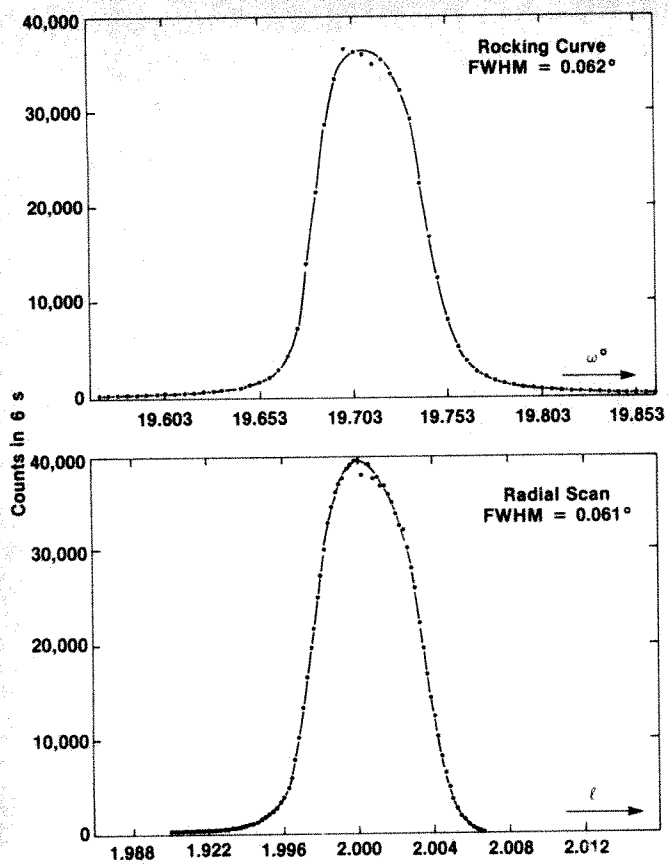

Fig. 2 Scans through the 002 reflection from the 800-μm^3 cancrinite crystal (no. 2). The upper, rocking curve indicates the mosaic spread of the crystal.

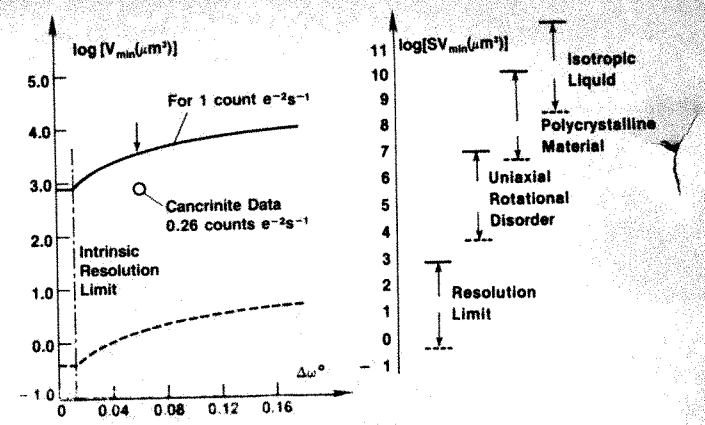

Fig. 3 The minimum crystal volume, V_{min}, that is required to provide a peak count rate of 1 count per electron^2 per s plotted against the rocking curve width or crystal mosaicity, $\Delta\omega^0$. The 800-μm^3 cancrinite crystal provided 0.26 counts per electron^2 per s (marked). The upper (solid) lines refer to the conditions under which the present measurements were made. The lower (dashed) lines represent the performance expected if an anticipated gain in flux of 2×10^3 is realized (see text). Extrapolation of these curves to $\Delta\omega = 180°$ (corresponding to uniaxial rotational disorder), to peak broadening in the second dimension (representing a random collection of crystallites or 'powder' sample), and finally to peak broadening in 2θ space permit the estimation of the minimum sample volumes (SV_{min}) required to provide 1 count per electron^2 per s at peak from other types of sample (right-hand portion of figure).

(no. 1) and 6 (no. 2) counts s^{-1}. We believe that the background levels could be further reduced by improved crystal mountings, optimized collimation and use of evacuated or helium flight paths. (Background rates as low as 0.1 counts s^{-1} have been achieved in similar experiments on this beam line.)

The size of the smallest measurable crystal will depend on the structure factor (SF) and the counting time allowed to reach a specified signal-to-noise ratio. We will adopt, for illustrative purposes, a very weak SF of 10 electrons, and 100s to achieve 1% statistical accuracy at the peak position. Since in 100 s the background (at 0.1 counts s^{-1}) is expected to be only 10 counts, it can be ignored but larger background rates can obviously increase the minimum measurable volume. In our experiment we recorded equivalent to 0.26 counts per electron^2 per s or one-quarter of the required accuracy. A complete data set of high precision could thus have been obtained from a 3×10^3 μm^3 crystal in the conditions of the present experiment.

In optimized beam line conditions, use of a shorter X-ray wavelength and the new Wiggler beam line, one would obtain an enhancement of flux of 2×10^3–2×10^4, with a concomitant reduction in the minimum measurable crystal volume. Thus, in these optimum conditions, complete high-precision data sets could be measured from crystals having volumes less than 1 μm^3.

It is the brightness of the synchrotron source, the incident

Table 1 Data from radial and rocking-curve scans of crystals

Scan no.	Crystal	Reflection	Type	Background*	Peak*	Intensity*	FWHM (deg)

Crystal no.	Crystal volume	Reflection	F_{hkl}	ω(rad s^{-1})	E	I_0
1	$13{,}000\times10^{-18}$	002	165	2.424×10^{-5}	9.55×10^6	5.24×10^{15}
1	$13{,}000\times10^{-18}$	004	105	1.897×10^{-5}	1.53×10^6	2.54×10^{15}
2	800×10^{-18}	002	165	1.505×10^{-5}	6.36×10^5	3.53×10^{15}

Cancrinite unit cell, $a = 12.69$, $c = 5.16$ Å, $V = 727$ Å^3, space group $P6_3$. The structure factor in electrons, F_{hkl}, was taken to be that measured from a much larger crystal of the same composition on a CAD-4F diffractometer[8]. E is calculated as $I_\omega \cdot f_a$, where I_ω is the integrated intensity recorded in the ω-scan (normalized to the same beam current as the first scan) and f_a is an estimated correction for the diffracted beam collimation in 2θ space (defined as the ratio of the total area of the gaussian of halfwidth FWHM (Table 1) to the area of the gaussian encompassed by the collimation).

photon flux per resolution element, that is the key parameter in this application. At the optimum, the sample mosaic width would match the intrinsically high resolution of the source, but for the crystals studied here, which we believe to be fairly typical, the mosaic width (0.062°) is four times greater than the inherent beam divergence (0.014°). The narrowing in the peak width that would accompany an improvement in crystal quality would enhance the peak count rate and hence further reduce the minimum required sample volume (Fig. 3). To push the technique to its size limit, crystals with a high degree of perfection will be required, although in this size regime one might expect that the smaller the crystal size, the greater the likelihood of crystal perfection.

In many fields great importance is attached to structural characterization and to proper interpretation of the interplay between structure and properties. Although single-crystal diffraction data are generally required for structure solution and detailed refinement, many materials do not occur in suitable single-crystal form. This has prompted widespread interest in the development of techniques for using powder data in optimizing structures that are already approximately known[11]. With powder data, particle-size broadening effects generally become apparent for average particle dimensions less than 0.2 μm. Our present results indicate that polycrystalline samples in which such effects are not observed can in many cases be regarded as large selections of possible candidates for structure solution and analysis using single-crystal techniques at synchrotron facilities. *Note added in proof*: Bachmann *et al.*[12] recently described measurements on a CaF_2 microcrystal at DESY. Their conclusions are similar to those presented here.

Propagated temperature changes during onset and recovery of the 1982–83 El Niño

F. P. Chavez & R. T. Barber

Departamento de Oceanografia, Direccion de Hidrografia y Navegacion de la Marina del Peru, Gamarra 500, Chucuito, Callao, Peru

El Niño is the appearance of anomalously warm sea surface temperatures along the coast of Peru. El Niño is also associated with changes of sea level and thermocline depth which are linked to a large-scale interaction of the global atmosphere and tropical ocean[1–4]. Linear wind driven theory suggests that Kelvin waves are responsible for the El Niño thermocline displacements[3], but in model systems it is difficult to relate thermocline changes induced by Kelvin waves to the observed changes in sea surface temperature[5]. We have now examined daily sea surface temperatures along the coast of Peru and subsurface temperature records from the Galapagos and 10° S and 79° W (Fig. 1) made during onset and recovery of the 1982–83 El Niño[6]. Our data show that the onset of the anomalous warming in this region propagated at speeds slower than Kelvin wave speeds. The speed of travel calculated from changes in temperature from the Galapagos to the coast of South America and then poleward along the coast is extremely coherent, and during onset appears to be related to advective processes. The rapid decrease in sea surface temperature associated with recovery from the 1982–83 El Niño was propagated at much higher speeds, very suggestive of Kelvin wave dynamics.

In 1894 Eguiguren[7] noted that there was a correlation between the rainy years in northern Peru and warm ocean temperatures associated with the years in which the El Niño current was of unusual strength. Half a century later Bjerknes[8] linked these episodes of warm sea surface temperatures (SSTs) to large-scale meteorological events associated with the Southern Oscillation[1–4]. Recently Wyrtki[2] has argued that El Niño is a dynamic response of the entire Pacific basin to changes in large-scale wind forcing; the response of the ocean includes changes in sea level, thermocline depth and horizontal advection.

Observations have shown that changes in sea level propagate rapidly from the western Pacific to the east along the Equator and then poleward along the coast of Peru[9,10]. Linear wind driven theory suggests that these changes result from packets of Kelvin waves that are excited by anomalies in the trade wind field in the western and central Pacific[3]. Theory also suggests that Kelvin waves are responsible for the El Niño thermocline displacements. Analysis of the daily temperature changes in 1982 and 1983 conntribute to a description of the dynamic characteristics of El Niño and provide an interesting complement to the theory.

Temperature observations made from piers at Paita (5° S), Lobos de Afuera island (7° S), Pimentel (7° S), Supe (11° S) and Callao (12° S) are shown in Fig. 2. The Paita measurements are made at 0800 h daily while the others are averages of measurements made at 0600, 1200 and 1800 h daily. The Paita, Lobos de Afuera and Callao time series (Fig. 2*a*) show that the initiation of the temperature rise at these locations occurred on 23 September, 29 September and 18 October respectively. The speed of propagation of these temperature rises, assuming straight trajectories is 43.6 cm s^{-1} between Paita and Lobos de Afuera and 42.3 cm s^{-1} between Lobos and Callao (Table 1). Smith[11] reported that temperature measurements from a depth of 100 m on a current meter array located over the 150 m isobath

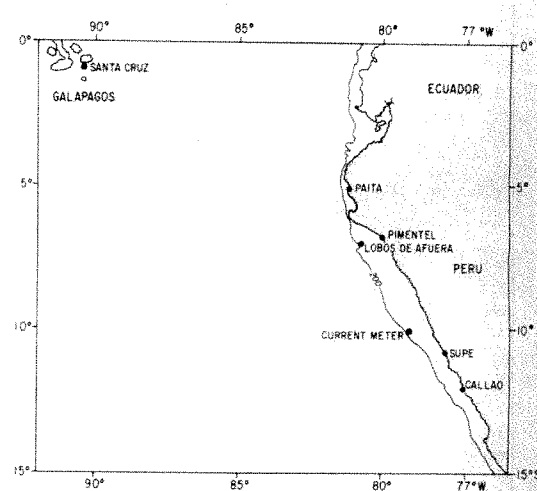

Fig. 1 Chart of the eastern equatorial Pacific showing the locations that provided observations for this article. The 200 fathom contour is included to show the position of the shelf break.

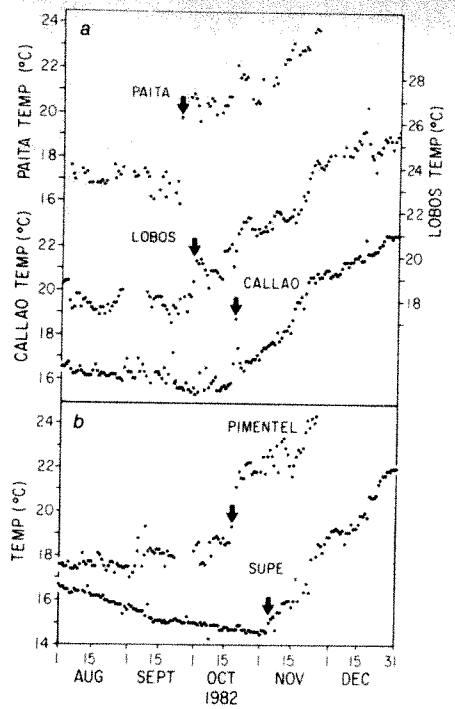

Fig. 2 Daily sea surface temperature observations made from piers at *a*, Paita (5° S), Lobos de Afuera (7° S) and Callao (12° S); and *b*, Pimentel (7° S) and Supe (11° S) during onset of the 1982–83 El Niño. Arrows indicate beginning of the temperature rise used to calculate propagation speeds.

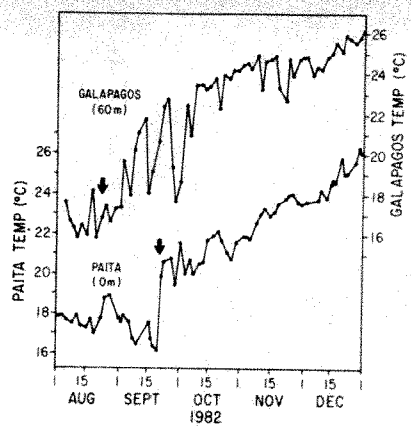

Fig. 3 Tri-weekly temperature observations from 60 m at Paita (5°05′ S, 81°16′ W) and Puerto Ayora, Santa Cruz Island, Galapagos Islands (0°47′ S, 90°17′ W). These locations are over the 100 m isobath. Arrows indicate beginning of the temperature rise used to calculate propagation speeds.

at 10° S showed the beginning of a change in temperature on 7 October. The temperature rise at the surface at a station offshore of Paita which is occupied tri-weekly over the 100 m isobath was first detected on 22 September (no observation made on 21 September). The propagating speed between the Paita offshore station and the 100 m current meter at 10° S is either 43.9 or 46.8 cm s^{-1}. Interestingly the poleward current at 100 m increased in speed from 19 to 36 cm s^{-1} between 6 and 7 October[11], a velocity similar to our calculations of the speed at which the onset of the temperature increase propagated.

Figure 3 shows the temperature time series from the Paita offshore station at 5° S and 81°17′ W and a parallel station maintained at Santa Cruz island at 0°47′ S and 90°17′ W in the Galapagos. The beginning of the temperature rise at 60 m in the Galapagos occurs on 23 August, in agreement with other reports from the islands that warming there began in mid August[12]. Assuming a straight line path directly from Santa Cruz to Paita (Fig. 1), the speed of travel of the temperature rise is 42.4 cm s^{-1}; assuming a maximum distance path along the Equator to the coast and then poleward down the coast the speed of travel is 60 cm s^{-1}, a speed used to describe the eastward propagation of the equatorial zonal SST gradient[13].

A second feature of the SST records from the Peru coast is that the increase in temperature at Pimentel (7° S) and Supe (11° S) (Fig. 2*b*) lag the other coastal stations. The calculated speed of travel from Lobos de Afuera to Pimentel (Fig. 1) is 5.1 cm s^{-1}. Mean onshore currents of 5.0 cm s^{-1} have been measured on the coast of Peru[14]; this velocity is surprisingly close to the calculated speed for the cross-shelf travel from Lobos de Afuera to Pimentel. Upwelling favourable winds along the coast of Peru remained strong throughout December 1982[11], so it is appropriate to assume that a typical cross-shelf upwelling circulation was maintained. Additional evidence for cross-shelf propagation of the temperature changes comes from the Paita offshore station which is 7 km from the coast. At the station the rise led the rise at the Paita pier; however, the tri-weekly sampling does not permit a precise calculation of travel speed over this short distance.

The lag in the temperature rise at Supe (11° S) is difficult to account for. If we assume that a route directly across the shelf from the 200 fathom contour (Fig. 1) then the speed of travel of the rise is calculated to be 4.6 cm s^{-1}. However, there is no reason to restrict the poleward undercurrent to the shelf break as observations during 1977[15] showed the undercurrent was on the shelf at 10° S and 12° S. The lag observed at Supe suggests that the local circulation must have shielded this location.

The mean SST field for this region in September[16] shows that there is a relatively small offshore gradient of SST (17 to 19° C in 100 km) so anomalous onshore surface transport would not result in a significant temperature signal, but there is a strong (17 to 25° C in 100 km) gradient in the alongshore dimension equatorward of Paita. The September 1982 rise in temperature at Paita shows an increase in temperature in a period of a few weeks which is similar to the mean alongshore gradient in that region. Large-scale horizontal temperature distributions[17] for the latter part of 1982 do not show significant changes until November, well after the temperature increases were observed at the shore stations. Our interpretation of this large-scale temperature increase in November 1982 is that it results from movement of the equatorial front southward; temperature, salinity and nutrient observations[18] support this interpretation.

The speed and spatial extent of the decrease in SST and subsurface temperatures associated with recovery from the

Table 1 Travel speeds of the appearance of the anomalous warming between locations shown in Fig. 1

From	On	To	On	Distance (km)	Time (days)	Speed (km day^{-1})	Speed (cm s^{-1})
Paita pier	23 September	Lobos pier	29 September	226	6	37.7	43.6

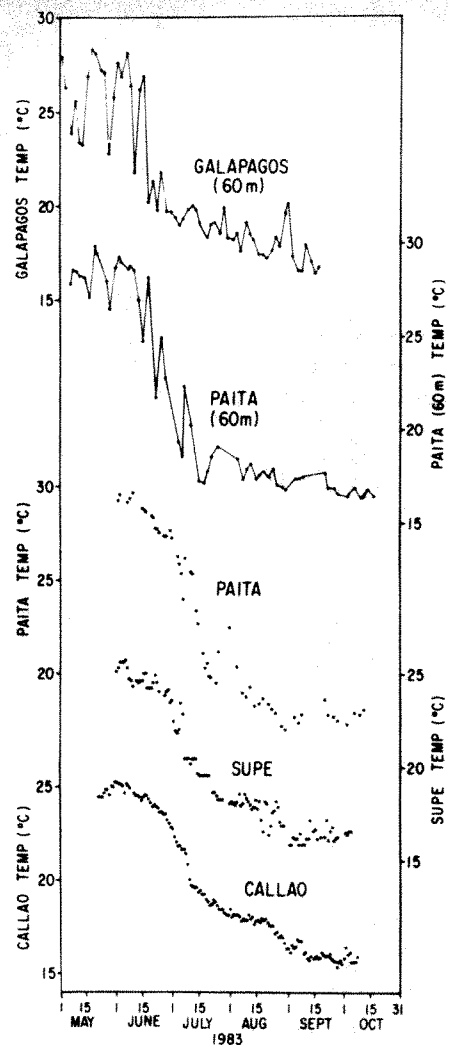

Fig. 4 Tri-weekly temperature observations from 60 m at Paita (5°05′ S, 81°16′ W) and Puerto Ayora, Santa Cruz Island, Galapagos Islands (0°47′ S, 90°17′ W) and daily sea surface temperature observations made from piers at Paita (5° S), Supe (11° S), and Callao (12° S) during recovery of the 1982–83 El Niño.

1982–83 El Niño are impressive. Figure 4 shows time series of temperatures from Galapagos (60 m), Paita (60 m), Paita, Supe and Callao during the recovery. Temperatures at 60 m in the Galapagos and Paita and SST from Paita, Supe and Callao drop almost simultaneously. From Fig. 4 it appears that recovery at 60 m in the Galapagos leads the Peru coast recovery and that recovery at 60 m at Paita leads the surface recovery at Paita. From 15 to 17 June there is a 6 °C temperature drop at 60 m at the Galapagos, and a similar drop (6 °C) is observed at the Paita 60 m station between the 17 and 22 June. Assuming a minimum distance path a propagating speed of 254 cm s^{-1} is calculated; assuming a maximum distance path following the coast and Equator the speed is 345 cm s^{-1}. This velocity domain is suggestive of Kelvin wave dynamics.

The 1982–83 El Niño differed from the canonical event described by Rasmusson and Carpenter[4] in that onset was some 6 months later in the year, so that during 1982 the anomalies in temperature along the coast of Peru appeared in September as opposed to February; this is important because the temperature fields off the Peru coast during September and February[16] are very different. The remotely forced perturbation in 1982 was, therefore, 'received' by a different thermal regime than the canonical event. Analysis of the day-to-day temperatures changes from previous El Niño events may help elucidate the mechanisms responsible for El Niño SST anomalies.

This research was supported in part by NSF grant OCE-8110702. The data for all Peru coastal stations, except Paita, were collected by the Direccion de Hidrografia y Navegacion de la Marina del Peru.

A wetter climate in eastern Sudan 2,000 years ago?

R. Mawson & M. A. J. Williams

School of Earth Sciences and Quaternary Research Unit, Macquarie University, North Ryde, New South Wales, 2113 Australia

Within the past 15 years accurate radiocarbon dating and plant microfossil analysis of tropical lake sediments in Africa and elsewhere have revealed that the early Holocene (11–7 kyr) was generally wetter than today throughout the tropics[1–4], in contrast to last glacial maximum (18 ± 2 kyr), which was cool, dry and windy[5,6]. Desiccation beginning ~4.5 kyr ago forced Neolithic herders to abandon previously habitable Old World deserts[7–9]. Less well known is the climate of proto-historic times (~2 kyr ago), when iron-smelting became important in Africa[10]. Here we present the first evidence that the Red Sea Hills were somewhat wetter at this time and suggest that this was also true of much of northern Africa.

Prompted by an early report of sub-fossil land and pond snails at Erkowit[11] in the arid Red Sea Hills of Sudan, we have collected, identified and dated freshwater molluscs from the alluvial clays which line the main valley near the original site. The mollusc and ostracod assemblage in all our samples is consistent with perennial stream flow some 2,000 years ago in an area now devoid of permanent rivers. The Erkowit plateau lies at 18°5′ N, 37°10′ E in the Red Sea Hills of eastern Sudan (Fig. 1). It rises over 1,200 m above the Red Sea, from which come frequent winter mists that help sustain sporadic *Euphorbia candelabra* and other evergreen Ethiopian upland plants[12,13]. Annual rainfall at Erkowit is ~300 mm, with twin peaks in January and August[14,15]. The surrounding country is much drier[15].

Up to 6 m of shell-bearing, alluvial clays are exposed in ephemeral stream channels like Khor Harasab where they overlie coarse angular gravels (Fig. 2). In nearby tributary gullies the clays sit unconformably on Basement Complex bedrock. Mantling the clays are sands up to 2 m thick, which are still being laid down. Over-grazing has led to gully erosion since the 1920s[11], with exposure of the fossiliferous clays.

In addition to the freshwater molluscs *Melanoides tuberculata* and *Bulinus truncatus*, both of which are common in the White Nile, Tothill[11] collected two other species of aquatic molluscs from the Erkowit clays (Table 1*a*). We have identified five species of aquatic snails scattered through the clays (Fig. 2 and Table 1*b*), but no land snails, in contrast to Tothill, who collected further from the valley bottom[11]. The ostracod assemblage

found in association with the freshwater mollusc assemblage (Fig. 2) indicates that the clays were laid down in permanent water.

We found shells scattered through the upper 4 m of alluvium, with rather more *Melanoides* and *Biomphalaria* near the top and bottom of the deposit (Fig. 2). The two ^{14}C dates were from these two levels, and do not differ significantly in age at one standard deviation. After cleaning in an ultrasonic bath and etching with dilute hydrochloric acid, SUA-1794 was counted for 1,760 min, and SUA-1795 for 5,000 min. Only *Melanoides* shells were dated. Each sample was tested by X-ray diffraction for recrystallization, using known proportions of powdered calcite and aragonite as standards. As a further check, we also tested shells of *Melanoides* collected alive from the lower White Nile and from Lake Lyadu in the southern Afar Rift. Despite the unavoidably small samples used for dating, we consider the ages reliable. The lower shell bed dates to 1,710 ± 160 yr BP (SUA-1794), the upper to 1,900 ± 110 yr BP (SUA-1795).

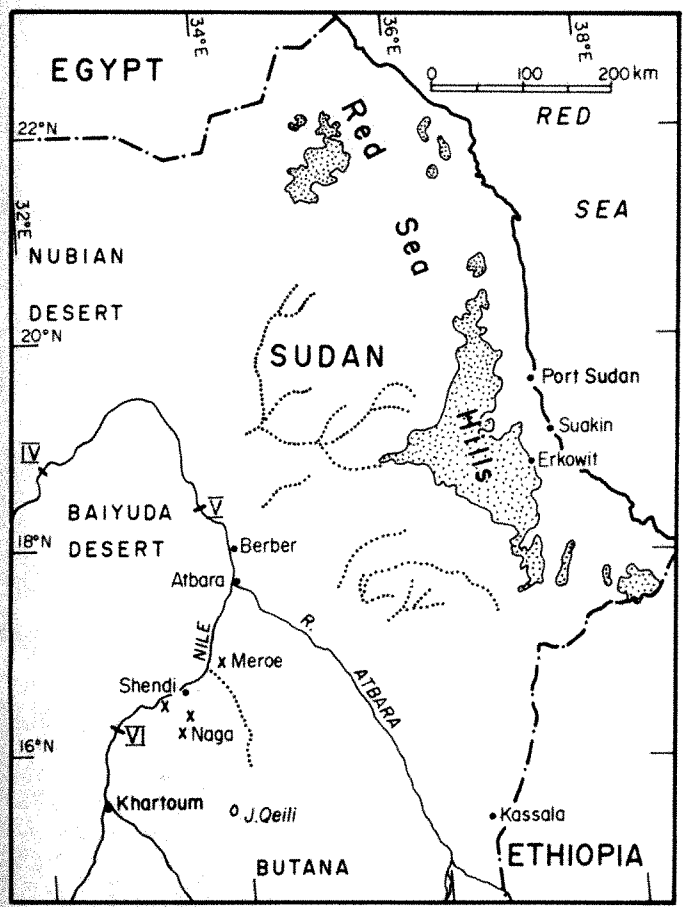

Fig. 1 Map of the northeastern Sudan showing location of Erkowit at the eastern margin of the Red Sea Hills. Crosses denote Meroitic sites (~2,000 yr BP), dotted lines are major ephemeral stream channels; land above 1,000 m is dotted; Roman numerals are Nile cataracts.

Of our ostracod assemblage, most species of *Cyprinotus* and *Darwinula* live in fresh water, but some are found in oligohaline to mesohaline water; *Canodopsis* is a freshwater form; and most *Ilyocypris* species are mud-dwellers[16].

Living non-marine charophytes inhabit fresh and brackish water[17]. They usually grow submerged in fresh standing water upon a muddy or sandy bottom, and often form extensive subaquatic meadows that may extend to depths of at least 10 m[18].

Of the molluscs, *Lymnaea* produces gelatinous eggs which dry up when removed from water. Adults can move outside water, but they are essentially aquatic as reproduction is impossible except in water. Modern habitats range from muddy or stagnant ponds and marshes to shallow, fast-flowing streams and lakes[20,21]. *Melanoides* is a wholly aquatic river or lake bottom species[21–24], but can survive in very shallow brackish water, albeit in dwarfed form, as in the eastern Afar desert. *Lentorbis junodi* lives in slow-flowing streams and marshes[24]. *Gyraulus connollyi* occurs today in stony or vegetated streams in the temperate uplands of southern Africa[24]. *Biomphalaria pfeifferi* inhabits stony and vegetated streams[24], seems intolerant of very high temperatures[25,26] and, unlike *B. sudanica*[27,28] is not found living in small seasonal pools or large swamps.

From the fossil evidence we infer that there was sufficient water on the Erkowit plateau towards 1,700–1,900 yr BP to sustain permanent stream flow in a landscape more densely vegetated than today, with flat-floored swampy meadows in the valley bottoms flanking mixed-load streams that were actively aggrading their channels with sandy or silty muds. More enduring rains during both winter and summer may have raised groundwater levels to the point where perennial base flow became possible.

Was the wetter climate at Erkowit a purely local phenomenon? We think not, as several independent lines of

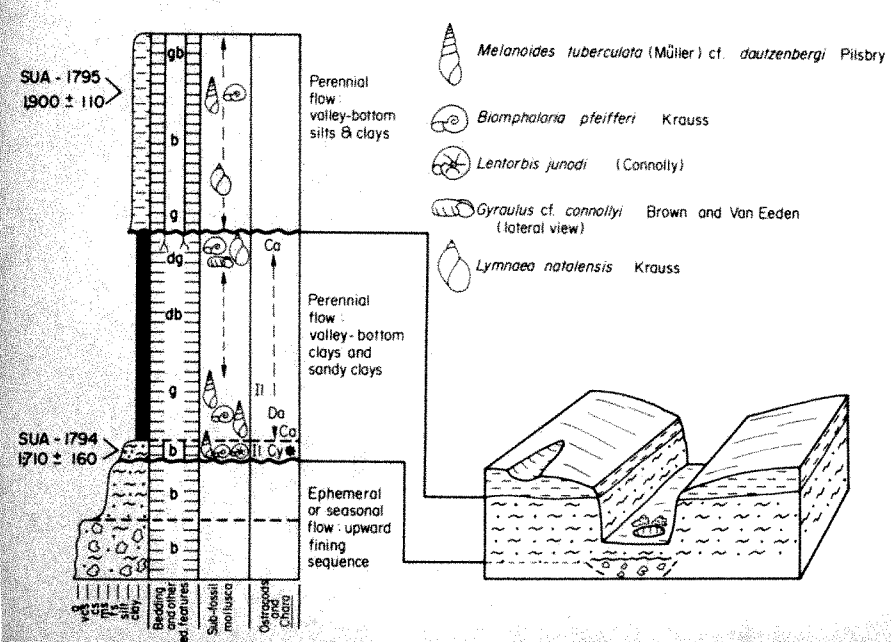

Fig. 2 Stratigraphy and local geomorphic context of the Erkowit shell-bearing clays. The ostracods are *Ilyocypris* sp. (Il), *Cyprinotus* sp. (Cy), *Canodopsis* sp. (Ca) and *Darwinula* sp. (Da). Broken arrows denote scattered distribution. The star denotes *Chara* sp. A and B. Bedding is massive (open dashes) or flat (closed dashes). Colour symbols denote brown (b), grey (g) and dark (d). The lithological symbols are clay as black, silt as dashes, sand as dots, and clay–sand mixtures as dots and wavy lines.

evidence point to a regionally wetter climate at about this time.

Short-lived lake transgressions are apparent at Lake Bosumtwi in Ghana soon after 2,400 BP[29], at Lake Abhe and other lakes in the Afar desert[30,31] towards 2,000–1,500 BP, and in the Ziway–Shala basin[32] of the Ethiopian Rift at ~1,600 BP. In the Chad basin several small interdune lakes are dated at 2,400 BP and 1,750 BP, at which time the Bahr el Ghazal had started to flow again[33,34]. There are also signs of reduced aridity in southern Libya between 1,930 and 1,435 BP, coeval with runoff from Tibesti[35] and with alluviation in the Hoggar[36].

In the Sudan, swamps reached to the foot of Jebel et Tomat on the lower White Nile during 1,930–1,600 BP[37]. The twin hills are now over 12 km from the closest riparian swamps[38]. The two centurions sent by Nero about AD 60 to find the sources of the White Nile reported that their way was blocked by vast swamps—the present Sudd. If the two rock outcrops that they saw within the swamp are indeed Jebel Ahmed Agha, as seems plausible, these are now 200 km beyond the northern edge of the Sudd[39]. The extensive iron smelting at Meroe (Fig. 1) presupposes abundant fuel for charcoal[40], and out in the Butana present runoff is not enough to fill the large Meroitic earth dams[39], nor to sustain much settlement[40–42]. Diodorus Siculus[39] wrote soon after 60 BC of cave-dwelling cattle herders in the Red Sea Hills who fought each other for pasture and retreated into swampy places. There are no such swamps today. In Alexandria at about this time Ptolemy recorded rare summer rains from southerly winds[39], suggesting that the Inter-Tropical Convergence Zone on occasion reached further north than it does today.

Taken together, the limnological, archaeological and archival evidence from Sudan, Egypt, Ethiopia, Chad, Libya and Ghana is entirely consistent with a regional climate somewhat wetter than today at about the time that freshwater molluscs were able to live in the now arid Red Sea Hills of eastern Sudan some 2,000 years ago.

We thank Dr Mike Barbetti and staff of Sydney University Radiocarbon Laboratory for dating difficult samples, Grant McTainsh and David Bell for the XRD analysis, John Cleasby for drawing the figures, and the Erkowit folk for their help.

Nutrient depletion indicates high primary productivity in the Weddell Sea

Joe C. Jennings Jr, Louis I. Gordon & David M. Nelson

College of Oceanography, Oregon State University, Corvallis, Oregon 97331, USA

The Southern Ocean, and in particular the Weddell Sea, have long been considered areas of high biological productivity[1], but recent isotopic measurements of primary productivity have not confirmed this view[2,3]. Because the large zooplankton and marine mammal populations of the Southern Ocean depend ultimately on phytoplankton as the base of the food web, accurate knowledge of primary productivity is essential to our understanding of the Antarctic ecosystem. Oceanographic data collected aboard the Soviet icebreaker *Mikhail Somov* have allowed us to derive a new productivity estimate, based on the seasonal depletion of nitrate, phosphate and silicic acid in the surface layer. From these depletions and data on the elemental composition of Southern Ocean phytoplankton, we estimate average primary productivity in the Weddell Sea in the spring-time to be 220–420 mg C m^{-2} day^{-1}. Our most conservative estimate is 1.5–4 times higher than recently reported measurements of productivity in the open ocean areas of the Southern Ocean[2–5]. Our estimates are inherently averages over time and space, including the effects of brief, intense spring blooms of phytoplankton which may occur near the receding ice edge[6–8]. Studies of primary productivity based on isotope uptake experiments, particularly in the austral summer, may fail to account for the significance of such blooms.

In October and November 1981, the joint US–Soviet Weddell Polynya Expedition aboard *Mikhail Somov* penetrated several hundred kilometres into the seasonal pack ice covering the eastern Weddell Sea, roughly along the Greenwich meridian. Preliminary results, including a description of the hydrographic regime and sea ice conditions, have been reported elsewhere[9–12].

The sub-ice surface waters comprised a very homogeneous mixed layer some 60–110 m thick in which dissolved nutrient concentrations were highest at the northernmost stations, decreasing slightly in the Weddell gyre proper. Because ice conditions restricted *Somov* to a relatively small sector of the northeastern Weddell gyre, it was necessary to examine the data set in the context of data from other cruises in the same area. Comparison of the nutrient data with austral summer data from GEOSECS and *Islas Orcadas* revealed that the austral summer data exhibited evidence of marked surface layer nutrient depletions. It was also apparent that virtually unaltered remnants of winter surface waters were present at several of the austral summer stations[12]. The existence of this unaltered winter water[13] (WW) at GEOSECS station 89, near the *Somov* track, with nutrient concentrations very similar to those in the winter surface layer, led us to derive an estimate of phytoplankton productivity from the net depletion of nutrients in the overlying surface waters.

Several assumptions are implicit in this approach to the estimation of seasonal nutrient depletion: (1) the separate summer and winter data sets (that is, different cruises) are quantitatively compatible; (2) little or no vertical or lateral mixing takes place to alter nutrient concentrations in either the surface layer or the WW layer beneath it; (3) a realistic time frame can be assigned over which the depletion of nutrients occurs; (4) vertical homogeneity in the surface layer under the ice is characteristic of late winter conditions in all years.

The hydrographic data used here were collected on the GEOSECS Atlantic cruise in 1972–73, *Islas Orcadas* cruise 12 in 1977 and the *Somov* cruise in 1981. The nutrient data from the GEOSECS and *Somov* cruises were obtained using the same automated techniques[14]; on *Islas Orcadas* manual techniques were used[15]. Intercomparisons of the nutrient chemical data on deep potential temperature and density surfaces confirm the comparability of the GEOSECS and *Somov* data, but the *Islas Orcadas* data appear to be systematically lower in dissolved silicic acid and higher in phosphate. In our calculations, we have used the *Islas Orcadas* data solely to illustrate the spatial extent of the nutrient depletion. Table 1 presents the temperature, salinity and dissolved nutrient data (phosphate, nitrate and silicic acid) we used.

Table 1 and Fig. 1 illustrate the evidence for stating that minimal vertical diffusion has occurred to alter the dissolved nutrient concentrations in either the surface layer or the WW. The *Somov* data show the temperature of the entire surface mixed layer beneath the ice to be almost at the freezing point. It is underlain by warmer, more saline water and would be heated from above by insolation as the ice recedes; thus, any substantial vertical mixing across the WW layer would cause an increase in its temperature. No such increase was observed (Fig. 1). Instead, a cold lens of remnant WW exists in the Weddell Sea. This was first noted half a century ago[16] but very few chemical observations have been available until recently. For the depletion calculations discussed here, we have used only the GEOSECS station at which the WW properties were demonstrably identical to those in the wintertime mixed layer (Fig. 1).

Generally, horizontal advection and mixing could also modify nutrient concentrations in surface waters above the remnant WW layer, but in the Weddell gyre lateral transport would do little to alter the apparent depletion of the surface waters relative to the underlying WW. There is a high degree of lateral homogeneity in the Weddell Sea, particularly in the zonal direction in which the major circulation occurs[16]. Additionally, circulation within the gyre is quite weak[9,17], and vertical shear between the surface and WW is not sufficient for the surface waters observed in the austral summer to have originated very far away from the underlying WW.

Dilution of the surface layer by melt water from the receding ice pack (mean thickness = 1 m) would cause an apparent depletion of nutrients in the surface layer. Adding 1 m of melt water to a surface layer 40 m thick (that is, a dilution of 2.5%) would account for ~7% of the observed nutrient depletion. Some of the *Islas Orcadas* stations we examined had surface salinities which were diluted by as much as 5% relative to the WW, which could account for 15–20% of the apparent nutrient depletion. At the austral summer GEOSECS station used in our calculations, the surface salinity is within 1% of the salinity of the WW layer, indicating that dilution effects were negligible.

The assignment of a time frame during which the observed nutrient depletion took place is somewhat problematical. The timing of the retreat of the pack ice is highly variable from year to year, usually beginning in mid-November[18,19]. November 1972 had the greatest extent of pack ice for the decade 1966–76[19], and it is thus unlikely that the GEOSECS station location was ice free until late November or early December. (The November ice extent data are the best indication of maximum annual ice extent available for the pre-microwave satellite era[19].) The GEOSECS observations were made during January 1973; therefore, we have assigned a 60–90 day time frame to the observed nutrient depletion.

The annual cooling of the surface layer at the onset of the austral winter results in the formation of a homogeneous surface layer before ice formation[16]. The *Somov* data indicate that this layer remains homogeneous in all properties throughout the winter; therefore little or no primary production occurs below the ice to alter the nutrient concentrations. Observations of very low levels of chlorophyll *a* and extremely limited light penetration of the pack ice during the *Somov* cruise[20] support the conclusion that primary productivity under the ice pack is minimal. Thus, the homogeneity of nutrient concentrations in the surface mixed layer at the end of austral winter can be assumed to be typical.

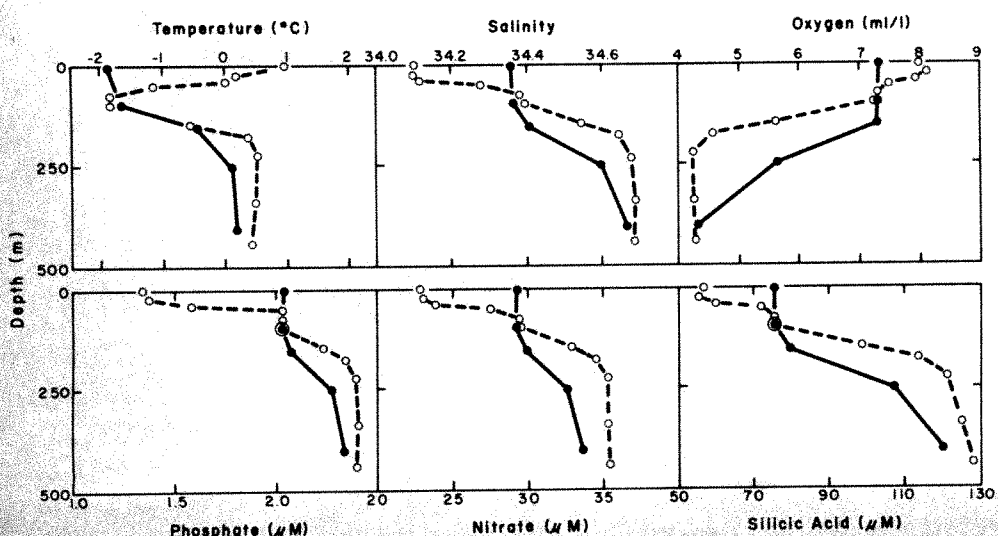

Fig. 1 Hydrographic properties at *Somov* station 35 at 59° 30′ S 0° 30′ E (solid lines) and GEOSECS station 89 at 60° 1.5′ S 0° 1.5′ E (dashed lines). The remnant winter water at the GEOSECS station is at 75–100 m.

Table 1 Winter water at GEOSECS 89 and wintertime surface water at WEPOLEX 35

Station	Pressure (db)	Potential temperature (°C)	Salinity (‰)	Silicate (μM)	Phosphate (μM)	Nitrate (μM)
GEOSECS 89	1	0.965	34.103	56.9	1.34	22.9
22 January 73	75	−1.830	34.383	75.7	2.03	29.4
60° 01′ S/0° 01′ E						
WEPOLEX 35	Entire	−1.858	34.358	75.7	2.04	29.3
12 November 81	surface					
59° 05′ S/0° 40′ E	mixed layer					

Figure 2 illustrates the spatial extent of the summer/winter contrast in dissolved silicic acid and phosphate concentrations in the eastern Weddell Sea. Because we believe the *Islas Orcadas* nutrient data to be systematically offset from the *Somov* data, we have used only the GEOSECS data to quantify the observed nutrient depletion. Taking the seasonal depletion to be the difference between the observed nutrient concentration and the WW nutrient concentration, the vertically integrated depletions at GEOSECS station 89 are 850 mmol m^{-2}, 27 mmol m^{-2} and 300 mmol m^{-2} for silicic acid, phosphate and nitrate, respectively. The average rates of depletion over the 60 and 90 day time frames assigned are shown in Table 2.

Our average nutrient depletion rates can be compared with experimentally determined rates of nitrogen and silicon assimilation by Antarctic phytoplankton. On recent cruises in the Scotia Sea[4,7], vertically integrated nitrate uptake rates were 0.74–2.41 mmol m^{-2} day^{-1} for those stations which were not in close proximity to a land mass. (An 18-h day has been used to convert from reported hourly rates.) Our most conservative estimate of the average daily nitrate depletion (Table 2) is 2.5–4 times the mean rate for these Scotia Sea stations. Similarly, for stations south of 60° S in the Pacific sector of the Southern Ocean, net production of biogenic silica in the euphotic zone was 2.5–4.5 mmol Si m^{-2} day^{-1} (ref. 21), compared with our calculated silicic acid depletion rates of 9.4–14.2 mmol m^{-2} day^{-1}. Therefore, the seasonal average depletion rates of both nitrate and silicic acid exceed by a factor of 1.5–5 the few available directly measured rates in the Southern Ocean.

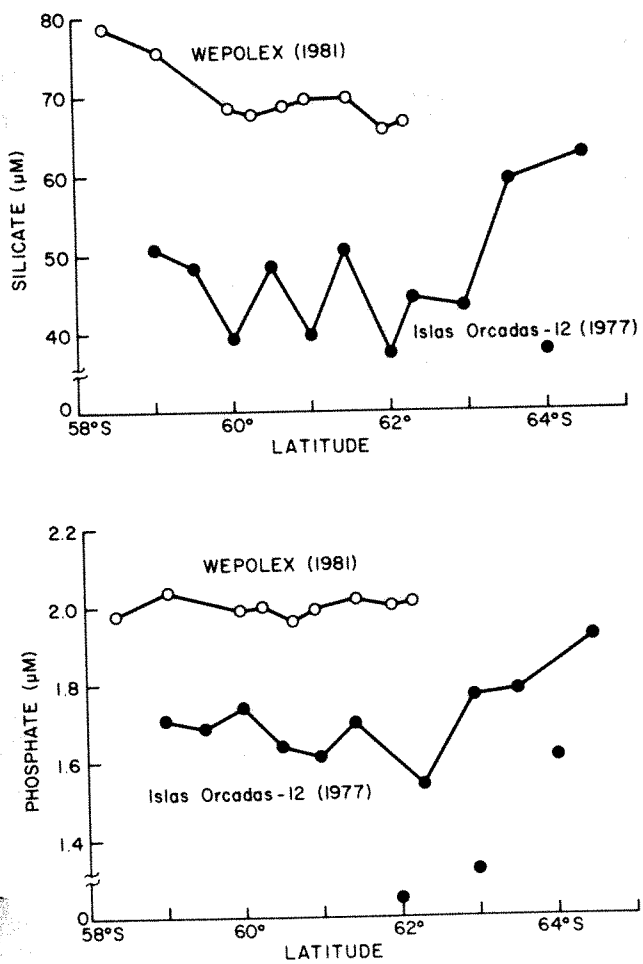

Fig. 2 Meridional distribution of dissolved silicic acid and phosphate in surface waters of the eastern Weddell Sea. *Islas Orcadas* data from summer 1977 are contrasted with *Somov* data from winter 1981 to illustrate the north–south extent of the apparent seasonal depletion.

The estimation of primary productivity from nutrient depletion requires knowledge of the stoichiometry of nutrient assimilation and carbon fixation by phytoplankton. The average composition of marine phytoplankton is often taken to be C/N/P = 106/16/1 (ref. 22), but lower C/N and C/P ratios have been reported for Southern Ocean phytoplankton[23]. Similarly, C/Si ratios for diatoms in the Southern Ocean are apparently lower than those for most marine diatoms[23]. We have used C/N/P = 62/11/1 and C/Si = 2.5 as representative of Antarctic phytoplankton[23]. Our estimates of average primary productivity are shown in Table 2. They range from ~220 mg C m^{-2} day^{-1} to 420 mg C m^{-2} day^{-1}.

Our lowest estimates of average primary productivity are based on phosphate and nitrate depletion occurring over a 90-day period. Because particulate nitrogen and phosphorus are remineralized more rapidly than is biogenic silica, they are more likely to be recycled within the euphotic zone. One aspect of this recycling is that some nitrogen is returned to the euphotic zone as ammonium by zooplankton excretion and microbial regeneration (see, for example, ref. 4). This ammonium is utilized preferentially by phytoplankton[4], so our nitrate-based estimate of primary productivity is inherently an underestimate. The estimate of primary productivity from nitrate depletion is considered to be that fraction of the total which is available for net transport up the food chain[4,7]. Available data on ammonium and nitrate uptake by Southern Ocean phytoplankton suggest that ammonium utilization supports 40–70% of the total productivity[4,7], so our estimate of nitrate utilization probably accounts for no more than half of the total. As only direct measurements of biogenic silica dissolution made in the Southern Ocean indicate that about one-third of the assimilated silicic acid dissolves in the upper 100 m[21], our silicic acid-based calculation may well be low by that amount. If our nitrate- and silicic acid-based

Table 2 Primary productivity estimated from nutrient depletion

Nutrient	Observed depletion (mmol m^{-2})	Depletion rate (mmol m^{-2} day^{-1}) 90-day interval	60-day interval	Estimated primary production (mg C m^{-2} day^{-1})
Silicic acid	850	9.5	14.2	282–426
Phosphate	27	0.30	0.45	223–335
Nitrate	300	3.4	5.1	223–335

primary productivity estimates are increased accordingly, they agree within 10%.

We believe that our calculations are conservative ones, resulting in estimates of primary productivity that are probably low, yet are 1.5–5 times higher than recent isotopic productivity measurements in the Southern Ocean[2,3,5,24]. Intense phytoplankton blooms have been reported near the edge of the receding seasonal ice pack which could easily account for much of the discrepancy between our calculated rates and those measured isotopically. Primary productivity in these blooms often exceeded 1 g C m^{-2} day^{-1} (refs 6–8, 24). As its seasonal ice cover recedes, most of the Weddell Sea surface is an ice edge zone for some period of the austral spring. A brief (10–15 day) bloom during which productivity was in excess of 1 g C m^{-2} day^{-1}, followed by a longer period of much lower productivity (closer to the ~0.1 g C m^{-2} day^{-1} values of the recent literature[2,3,5,24]), would result in seasonal average rates similar to those we derive. The contribution of such blooms is inherently included in our calculations, but may be missed by discrete measurements which are remote from the ice edge.

We gratefully acknowledge the support of this work by the Division of Polar Programs of the US NSF (DPP80-107620 and DPP82-03529) and by the Arctic and Antarctic Institute of the USSR. We thank A. L. Gordon, leader of the US component of the Weddell Polynya Experiment, for his help; the scientists, officers and crew of *Somov* and our American colleagues for their support; and M. Sparrow and J. Ahern for technical support in our laboratories at Oregon State University.

Bacterial chemolithotrophy in the ocean is associated with sinking particles

D. M. Karl*, G. A. Knauer†, J. H. Martin† & B. B. Ward‡

* Department of Oceanography, University of Hawaii, Honolulu, Hawaii 96822, USA
† Moss Landing Marine Laboratories, Moss Landing, California 95039, USA
‡ Scripps Institution of Oceanography, La Jolla, California 93093, USA

The oceanic carbon cycle has traditionally been viewed as a reversible, one step reduction–oxidation reaction ($CO_2 \rightleftharpoons CH_2O$). Principle pathways were thought to involve eukaryotic photoautotrophy and oxygen-dependent bacterial respiration, respectively. However, prokaryotic (cyanobacterial) photoautotrophy is now well documented and has even been proposed as a major carbon pathway[1–6]. In a previous study of the mesopelagic zone in the North Pacific Ocean[7], the observed downward fluxes of organic carbon, nitrogen, ATP and RNA suggested production *in situ* of new particulate organic carbon at 700–900 m. Here we present evidence that this is indeed the case and that it is mediated by bacterial chemolithotrophy. Energy for this process may be in part provided by detrital NH_4^+ derived from the downward flux of large particles.

In order to reconcile the mesopelagic zone carbon budget, chemolithotrophic production of organic matter was proposed as a possible mechanism[7]. During the Vertex III sediment trap experiment, we had an opportunity to examine the possibility of bacterial chemolithotrophic production at a station, located in the eastern tropical North Pacific Ocean approximately 330 km off Manzanillo, Mexico (15°55′ N; 107°12′ W). The Vertex III free floating sediment trap array, used for 20.6 days, consisted of 168 individual collectors at 14 depths (50–2,000 m). Details of the trap construction are given elsewhere[8]. To test the chemolithotrophy hypothesis, we used five sediment trap collectors at each of five depths (100–750 m). Measurements included: (1) concentration of ATP extracted *in situ*[9] to estimate the biomass of living microorganisms associated with sinking particles, (2) shipboard-extracted ATP concentrations[7] in unpreserved traps to estimate the net *in situ* changes in biomass during the experiment (see Table 2), (3) concentrations of NH_4^+, NO_2^- (see Table 1), (4) organic carbon and nitrogen concentrations[8], (5) rates of microbial DNA synthesis *in situ*[7], (6) microbial incorporation of $^{14}CO_2$ (see Table 2), and (7) microscopic examination of glutaraldehyde-fixed sediment trap samples. The *in situ* ^{14}C-incubation experiments and ATP measurements were performed in paired sediment traps, with and without the addition of a mixture of potential chemolithotrophic substrates (see Table 2).

Several results suggest the activity of chemolithotrophic bacteria at these depths. First, the concentration of NH_4^+ measured in the sediment trap solutions (and hence, the corresponding downward fluxes of particle-associated NH_4^+) increased between 100 and 150 m (Table 1), indicating production of NH_4^+ in association with descending particles, scavenging of NH_4^+ from the water column during descent or horizontal advection of particle-associated NH_4^+. At greater depths both concentration and flux of NH_4^+ consistently decreased. The estimated NH_4^+ fluxes are considered to be minimum values as no attempt was made to remove associated or covalently bound NH_4^+ from the sinking particles. The flux of NH_4^+ thus calculated was 383 and 149 μmol m^{-2} day^{-1} at 150 and 550 m, respectively, indicating a loss of 234 μmol NH_4^+ m^{-2} day^{-1} over this depth interval (Table 1). Since NH_4^+ was undetectable (< 0.05 μmol l^{-1}) in this portion of the water column, we suggest that the NH_4^+ is consumed either in the water column or within the sinking particles at a rate which is equivalent to the measured rates of change (mean rate of 0.59 μmol m^{-3} day^{-1} between 150–550 m). The consumption of NH_4^+ (that is, $-\Delta NH_4^+/\Delta Z$) is associated with the appearance of NO_2^- (Table 1). These data suggest the presence of active bacterial nitrification.

Nitrifying bacteria of the genera *Nitrosomonas* and *Nitrosococcus* were counted using specific immunofluorescence techniques[10,11]. Nitrifiers were detected in high concentrations in all sediment trap collections and the majority were *Nitrosomonas*-type cells. Nitrifiers were frequently observed in clusters of up to 30 cells, but single and paired cells were also common. The mean cell size varied considerably, but large cells, up to 3 μm in diameter, were common.

Table 1 Nutrient concentrations, fluxes and average rates of change over the specified depth intervals

* NH_4^+ and NO_2^- concentrations were measured in 0.22 μm filtrates of the unpreserved sediment trap solutions receiving no chemolithotrophic additions (see Table 2). Samples were analysed by S. Moore within 4 h after sediment trap recovery using a shipboard Technicon Autoanalyzer system.
† Organic C and N were measured in formalin preserved sediment traps as described by Knauer *et al.*[8].

The downward flux of particle-associated nitrifiers was consistently high (1.15 to 3.52×10^8 cells m^{-2} day^{-1}) throughout the depth range of our experiment (100–750 m). Sediment traps pre-charged with chemolithotrophic substrates and incubated *in situ* produced higher cell densities, with values (relative to the control) ranging from 118% (150 m) to 263% (550 m). If we assume a maximum nitrification rate of $1.4–2\times10^{-12}$ mol NH_4^+ per cell per day (refs 12, 13) the particles collected at 550 m are potentially capable of oxidizing between 160–230 μmol NH_4^+ m^{-2} day^{-1}, a value which agrees with the observed loss of NH_4^+ at 150–550 m (Table 1).

The comparison of *in situ* versus shipboard extracted ATP can be used to ascertain the extent to which net microbial growth had occurred in the unpreserved sediment materials during the experiment[7]. It is evident (Table 2) that the two surface traps (100 and 150 m) exhibited post-incubation decreases in total ATP (that is, shipboard ATP < *in situ* ATP) indicating net microbial death. However, for that region of the water column where NH_4^+ was consumed and NO_2^- was produced (550–750 m), there was an increase in total microbial ATP during the incubation period and hence, net carbon production. The greatest increase occurred at 550 m (Table 2). At all three depths where net growth had occurred (550, 650 and 750 m), we observed an increased biomass yield following the addition of potential chemolithotrophic substrates.

The mean total $^{14}CO_2$ incorporation (Table 2) also displayed a mid-depth (550 m) maximum and, at all depths but 750 m, the incorporation rates were stimulated by the addition of inorganic substrates. However, $^{14}CO_2$ incorporation data, by themselves, cannot be extrapolated directly to microbial carbon production without information on the proportion of autotrophic versus heterotrophic processes. Heterotrophic bacteria normally assimilate 2–10% of their total carbon cell quota as CO_2 (refs 14–16), whereas certain chemolithotrophs obtain potentially 100% of their cell carbon requirements from CO_2 (refs 17, 18). By assuming the ^{14}C-incorporation data represent strictly chemolithotrophic growth, the data can be extrapolated and compared with total microbial carbon production derived from estimates of DNA synthesis (Table 3). The DNA synthesis (^3H-adenine) technique does not discriminate between the two major pathways of carbon synthesis and hence provides an estimate of total microbial carbon production. In the surface sediment traps (100 and 150 m), total microbial production greatly exceeds the ^{14}C-derived estimate, indicating that chemoheterotrophic processes predominate (Table 3). This is consistent with the observed loss of organic carbon and production of NH_4^+ associated with the large sinking particles (Table 1). However, between 550 and 750 m chemolithotrophic carbon production was detected with estimates ranging from 7% (650 m) to 90% (550 m) of the total microbial production and may therefore be a significant, if not dominant pathway for carbon and energy flow at certain depths in the mesopelagic zone.

If we assume that nitrification is the dominant pathway we can calculate a minimum amount of energy required to sustain this observed mesopelagic bacterial production. The oxidation of NH_4^+ to NO_2^- proceeds with a ΔG of −66 kcal mol^{-1}, and with typical cell yields of 0.03–0.06 mol C produced per mol N oxidized[19]. Thus at 550 m, the estimated chemolithotrophic microbial production (425 μg C m^{-2} day^{-1}) would require a flux of 787 μmol NH_4^+ m^{-2} day^{-1}, if nitrifiers were exclusively responsible, which is a value approximately three times the

ATP associated with sinking particles was extracted *in situ* by precharging the sediment traps with a high density acid-salt solution (0.5 M H_3PO_4, 1.5 M NaCl $\rho = 1.05$ g cm^{-3}) as described by Fellows *et al.*[9]. For *in situ* incubations paired sediment traps were prepared for each depth by precharging with 2.5 l of an autoclaved high density solution consisting of 0.22 μm filtered seawater containing 33.8 g NaCl, 14.3 g $MgCl_2 \cdot 6H_2O$, 0.93 g KCl and 30 μCi $NaH^{14}Co_3$ (50 m Ci $mmol^{-1}$; New England Nuclear) per litre ($\rho = 1.065$ g cm^{-3}). At each depth, one of the paired traps received the chemolithotrophic mix consisting of NH_4Cl, $Na_2S_2O_3 \cdot 5H_2O$ and $MnCl_2$ to yield final concentrations of 400 μM NH_4^+, 400 μM $S_2O_3^{-2}$ and 100 μM Mn^{+2}. Shipboard ATP concentration refers to the value measured in the unpreserved sediment traps after recovery so as to distinguish it from the *in situ* extracted ATP. Details of the methods are presented by Karl and Knauer[7]. For ^{14}C incorporation, triplicate subsamples (100 ml each) were concentrated onto Whatman GF/F filters acidified with HCl, evaporated to dryness *in vacuo*, reconstituted with 1 ml deionized H_2O, mixed with 10 ml Aquasol (NEN) and radioassayed.
* Calculated as: [(shipboard ATP − *in situ* ATP)/*in situ* ATP] × 100%.

See Table 2 for composition of chemolithotrophic mixture.

* Calculation assumes that CO_2 represents 100% of the carbon cell quota (that is obligately chemolithotrophic) and is based upon the measured initial ^{14}C specific radioactivity of 15 μCi mmol^{-1} of total inorganic C. Values are mean ± 1 s.d.

† Total carbon production extrapolated from *in situ* measurements of rates of DNA synthesis using the conversion factors of Karl and Winn[20]. Values are mean ± 1 s.d.

‡ Calculated from data obtained without chemolithotrophic additions.

minimum *in situ* NH_4^+ consumption rate estimated from the sediment trap data (Table 1). This rate of NH_4^+ oxidation could consume potentially 1.6 mmoles $0_2\ m^-2\ day^{-1}$, if completely oxidized to NO_3^-. Therefore, chemolithotrophy (bacterial reduction of CO_2 and concomitant O_2 consumption) rather than chemoheterotrophic utilization of surface-dervied organic matter may be an important mechanism for the consumption of O_2 in the mesopelagic zone of the ocean. Although we have singled out nitrification as an important metabolic process, other pathways such as the oxidation of CH_4, H_2S, H_2 and other reduced products of anaerobic decomposition may also contribute energy for the observed mesopelagic production.

These results suggest that the oceanic carbon cycle may be more complex than previously described. The flux of energy descending from the euphotic zone may greatly exceed that nominally contained in particulate organic detritus, which has previously been considered to be the principle factor controlling the rates of mesopelagic microbiological activity and O_2 utilization. Although the flux of energy (in the form of reduced products of bacterial decomposition) required to sustain the chemolithotrophic production measured in this study is probably derived from surface primary production and thus cannot exceed it in steady-state conditions, mesopelagic 'primary' production may have a major impact on the trophic organization of localized mid-water food webs and on the production and maintenance of the intermediate depth O_2 minimum.

We thank the officers and crew of the *RV Wecoma* and *RV Cayuse* for their help in sample collection; D. Burns, C. Hunter, S. Fitzwater and S. Moore for technical assistance. Natural killer (NK) activity[1] against tumour and virus-infected target cells is shown by a subpopulation of peripheral blood mononuclear leukocytes with the morphological features of large granular lymphocytes (LGL)[2]. The lineage of human LGL is still controversial, as they display surface markers of both T lymphocytes and myelomonocytic cells[3]. LGL have recently been reported to produce lymphokines such as interleukin-2 (IL-2)[4,5] and α- as well as γ-interferons[6], functions associated mainly with T cells. To determine whether cytokines associated with other cell lineages are also produced by LGL, we examined whether they might produce a myelomonocyte-associated cytokine such as interleukin-1 (IL-1). IL-1 is a 12–18,000 molecular weight (MW) lymphokine produced by a variety of cell types such as monocytes[7], keratinocytes[8] and a human dendritic cell line[9], which plays a crucial role in immunoregulation and inflammation[10,11]. Moreover, IL-1 has recently been reported to act synergistically with IL-2 and interferons in boosting LGL-mediated NK activity[12]. We now show that a subset of highly purified human LGL with NK activity can be stimulated to secrete a soluble factor with the biochemical and biological characteristics of human IL-1.

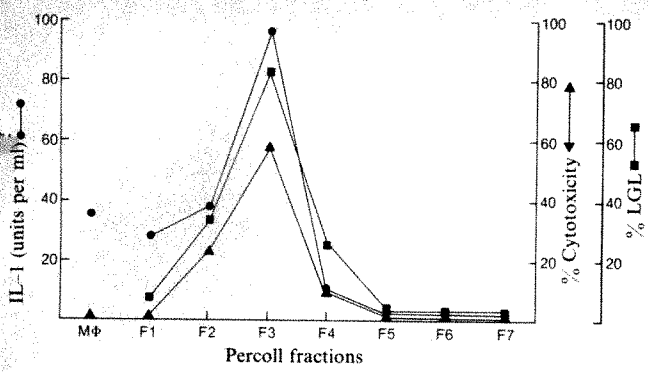
LGL were isolated from healthy volunteers by sequential elutriation, removal of adherent cells on a plastic surface and nylon wool columns, and centrifugation on a discontinuous Percoll density gradient[2]. Cells from the resulting fractions were tested for lysis of NK-susceptible tumour target cells and for

* Present address: Institute of Biological Chemistry, 2nd University Medical School, via S. Pansini 5, Naples, Italy.



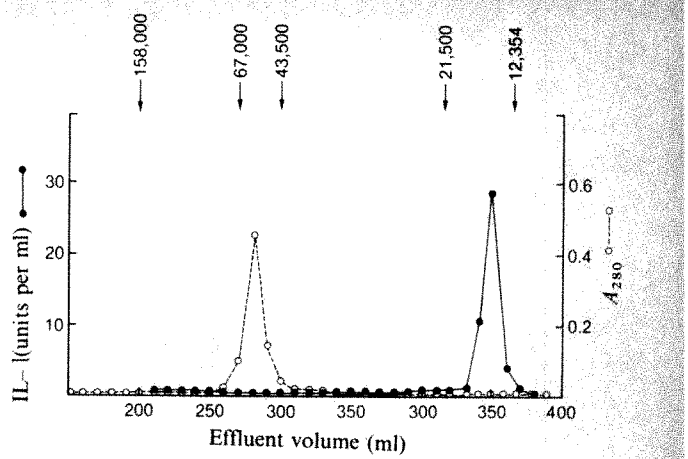


Fig. 1 IL-1 production and NK activity in fractions of peripheral blood lymphocytes separated by discontinuous Percoll density centrifugation. Peripheral blood lymphocytes were isolated and fractionated by centrifugal elutriation and lymphocyte-enriched fractions were depleted of adherent cells first by incubation on autologous serum-coated plastic flasks for 1 h at 37 °C and second, by passage over nylon wool columns. The nonadherent cells were then fractionated on a seven-step discontinuous Percoll (Pharmacia) density gradient[2]. RPMI 1640 medium + 10% fetal calf serum (FCS) and Percoll were adjusted to 285 mosmol per kg H_2O. Seven different concentrations of Percoll in medium were prepared, ranging from 40 to 57% Percoll, each varying from the next by 2.5% concentration steps. 1×10^8 peripheral blood lymphocytes were applied to each gradient and centrifuged at 550*g* for 30 min at 20 °C. The seven fractions were collected and washed. NK activity was measured in a 4 h ^{51}Cr-release assay against K562 at an effector:target ratio of 50:1 (ref. 2). For IL-1 production of 1×10^6 ml^{-1} in RPMI 1640 supplemented with 2 mM glutamine, 2 mg ml^{-1} HSA (American Red Cross) and 50 μg ml^{-1} gentamicin. Adherent monocytes were detached from the surface of plastic flask by flushing with cold PBS containing 10% FCS and resuspended at 1×10^6 ml^{-1} in the same human serum albumin-supplemented medium. Cells were then cultured for 48 h (5% CO_2, 37 °C) in the presence of 25 μg ml^{-1} LPS. Supernatants were collected, dialysed extensively against PBS (0.15 M NaCl, 0.02 M phosphate, *p*H 7.2) containing 0.01% polyethylene glycol (PEG) and 50 μg ml^{-1} gentamicin. The filtered samples (0.22 μm, Millex) were tested for IL-1 activity in a thymocyte co-stimulator assay, as described previously[30]. A single-cell suspension of C3H/HeJ (H-2^k) mouse thymocytes were cultured for 72 h at 1.5×10^6 cells per well in 96-well flat-bottomed plates in the presence of 0.5 μg ml^{-1} concanavalin A and with serial dilutions of the test samples or a standard preparation of IL-1. Results from triplicate cultures were plotted on linear regression against the standard preparation of IL-1 (set up at 100 units ml^{-1}) and expressed in units ml^{-1}. In every IL-1 assay a sample of medium with 25 μg ml^{-1} LPS was tested and was consistently negative (< 1 unit ml^{-1}). Each sample from this and the following experiments was negative for IL-2 activity when tested on the IL-2-dependent CT6 cell line[31] and was found free of contaminating IL-2. This experiment was repated four times with similar results. The percentage of LGL of each fraction of Percoll gradient was determined by morphological examination of Giemsa-stained cytopreps[2]. MΦ, macrophages.

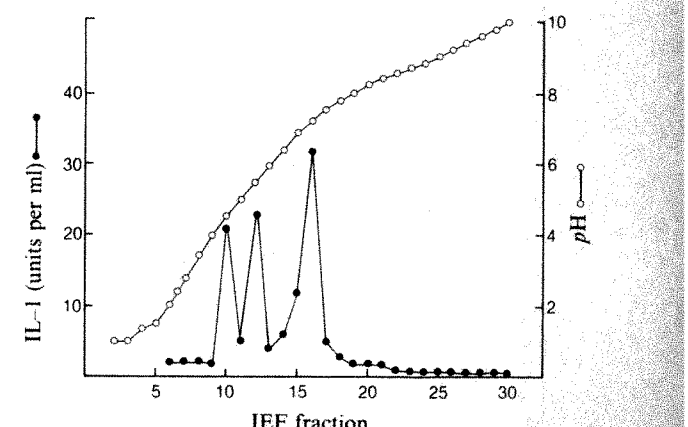

Fig. 2 Biochemical characterization of IL-1 derived from cultured LGL. 6×10^7 LGL, collected after 3 weeks' culture as described in Table 1, were washed three times with RPMI 1640 and cultured for 48 h (5% CO_2, 37 °C) in the presence of 25 μg ml^{-1} LPS at 2×10^6 cell ml^{-1}. Supernatants were collected and 47.6 g $(NH_4)_2SO_4$ per 100 ml supernatant were gradually added under gentle stirring to a final concentration of 75%. The precipitated proteins were collected by centrifugation at 5,000*g* for 10 min, resuspended in PBS and dialysed extensively against PBS (with 0.01% PEG and 50 μg ml^{-1} gentamicin). The sample was concentrated using an Amicon ultrafiltration unit with PM10 Diaflo membrane (Amicon) and dialysed against PBS as above. Aliquots of 2 ml were applied to a Sephacryl S200 (Pharmacia) packed column (2.5 × 90 cm). The column was calibrated with the following markers: aldolase (158,000 MW), bovine serum albumin (67,000 MW), ovalbumin (43,500 MW), soybean trypsin inhibitor (21,500 MW), and cytochrome *c* (12,354 MW). The sample was eluted at a flow rate of 20 ml h^{-1} with PBS (0.01% PEG, 50 μg ml^{-1} gentamicin). Aliquots (3 ml) were collected, filtered and tested for IL-1 activity as described in Fig. 1 legend. The fractions active in the IL-1 assay (Fig. 2, upper panel) were pooled, concentrated by Amicon ultrafiltration unit as described above, and dialysed extensively against 0.01% PEG. The sample was loaded onto a preparative isoelectric focusing column (LKB) in a 100 ml of 5–50% sucrose gradient with 0.01% PEG and 2% *p*H 3.5 to 10 ampholites (LKB). The *p*H gradient was formed over a period of 18 h at 1,600 V. 3-ml fractions were collected and the *p*H was determined (Fig 2, lower panel). Fractions were dialysed extensively against PBS (0.01% PEG, 50 μg ml^{-1} gentamicin), filtered and tested for IL-1 activity as described in Fig. 1 legend.

production of IL-1 upon stimulation with lipopolysaccharide *Escherichia coli* 055 B:55 (LPS) (Fig. 1). Cytochemical and cell surface analysis revealed that fraction 3 contained predominantly LGL (80–85%), enriched in cells with NK-associated markers (67% OKMI$^+$, 62% OKT10$^+$, 75% B73.1$^+$), but depleted of cells with non-NK associated markers (5% OKT3$^+$, < 1% surface Ig$^+$) and contained no detectable monocytes (< 1% esterase-positive cells)[3,13]. LPS stimulated IL-1 secretion by cells in fractions 1 and 2 which contained monocytes (30–40% and 5–10% respectively, other cells being large agranular lymphocytes) and in fractions 3 and 4 which were enriched in LGL but depleted of monocytes (< 5%) (Fig. 1). On a per cell basis, the LGL-enriched fraction 3 produced threefold higher levels of IL-1 than the monocyte-containing populations and substantially more than a purified population of adherent monocytes. Moreover addition of > 5% of autologous adherent monocytes to LGL decreased the production of IL-1 from 164 units per ml to 33 units per ml (data not shown).

LGL-enriched populations from fraction 3 were purified further to remove T cells and macrophages by treatment with the monoclonal antibodies anti-OKT3 (T-cell specific[14]) and anti-Leu-M1 (monocyte–granulocyte specific[15]) + complement (C). After this treatment, LGL (≤ 1% OKT3$^+$, < 0.3% Leu-M1$^+$) showed significantly greater LPS-induced IL-1 activity on a per cell basis than untreated LGL (Table 1).

The data in Table 1 suggested that OKT3$^+$ T cells and Leu-M1$^+$ macrophages might suppress production of IL-1 by LGL.

Expt 1: LGL were isolated by discontinuous Percoll gradient (fraction 3) and washed three times with RPMI 1640. Aliquots were treated with optimal cytotoxic concentrations of the indicated antibody + complement (low Tox-H rabbit complement, Cedarlane) at 1:10 final dilution. Cells were washed 3× with RPMI 1640 and resuspended in human serum albumin (HSA) supplemented medium at 1×10^6 per ml. Adherent monocytes were resuspended with cold phosphate-buffered saline (PBS) containing 10% fetal calf serum (FCS) and treated with the monoclonal antibodies as indicated. Both LGL and macrophages were stimulated with 25 μg ml^{-1} LPS as described in the legend to Fig. 1. The significance level of the data, related to controls, was calculated by Duncan's multiple range analysis of variance. P values of ≥ 0.1 were considered not significant. Data are expressed as the mean of six separate experiments. **Expt 2:** LGL from fraction 3 of Percoll gradient were treated with optimal cytotoxic concentrations of anti-OKT3 and anti-Leu-M1 antibodies + C. The resulting OKT3$^-$ Leu-M1$^-$ LGL were treated with optimal concentrations of the antibodies shown (5–10 μg ml^{-1}) and then labelled with F(ab)$_2$ goat anti-mouse fluoresceinated antibody (Cappel) at 1:10 final concentration. Cells were analysed and sorted in positive and negative fractions by flow cytometry (Ortho Cytofluorograph). When reanalysed, the positive fraction contained more than 98% positive cells. The negative fraction contained less than 2% positive cells. In all the experiments, the negative cell population was further treated with cytotoxic concentrations of the same antibody + C. Cells were stimulated as described in the legend to Fig. 1. This experiment was repeated twice with similar results. **Expt 3:** LGL (fraction 3 of Percoll gradient) and T lymphocytes from Percoll fraction 7 were cultured *in vitro* for 10 generations in medium supplemented with IL-2. Lectin-free human IL-2 (ABS) was used at 10% v/v. After 3 weeks cells were collected. These cultured LGL were treated with anti-Leu-M1 antibody and C as described in Table 1 legend. The cells, free of contaminating LeuM1$^+$ or nonspecific esterase-positive cells, were then stimulated for IL-1 production as described in Fig. 1 legend. IL-1 activity was determined as reported in Fig. 1 legend. This experiment was repeated three times with similar results. ND, not determined.

* NK activity was measured against K562 cell line in a standard 4-h ^{51}Cr-release assay at different effector: target ratios. Lytic units (LU) were calculated at 30% specific lysis per 10^7 effector cells.

Table 2 Enhancing activity of LGL-derived IL-1 on T-lymphocyte response to PHA and on fibroblast proliferation

IL-1 (units per ml)	T-lymphocyte + PHA (mean c.p.m. ± s.e.m.)	CRL 1445 fibroblast (c.p.m. ± s.e.m.)
0	760 ± 88	1,270 ± 90
10	8,571 ± 720	3,819 ± 228
20	14,492 ± 650	4,959 ± 520
40	15,924 ± 790	9,863 ± 454
80	21,038 ± 1,120	10,026 ± 760

OKT3$^-$, LeuM1$^-$ LGL were stimulated with 25 μg ml^{-1} LPS at 2×10^6 cells per ml for 48 h. Supernatants were collected, dialysed extensively and tested for IL-1 activity in C3H/HeJ mouse thymocyte assay as described in the legend to Fig. 1. Monocyte-depleted T lymphocytes from fraction 7 of Percoll density gradient were cultured at 2.5×10^5 cells per well in the presence of PHA 2.5 μg ml^{-1} and the indicated concentrations of LGL-derived IL-1 for 3 days. Cultures were pulsed for the last 8 h with 1 μCi ^{3}H-thymidine (1.9 mCi mmol^{-1}). Results are expressed as mean ± s.e.m. of triplicate cultures. This experiment was repeated twice with similar results. CRL 1445 human dermal fibroblasts (American Type Culture Collection) at third passage were plated in 96-microwell plates at 1×10^4 cells per well in Dulbecco's modified Eagle's medium containing 10% heat-inactivated (56 °C, 30 min) fetal calf serum, 4 mM glutamine, 20 mM HEPES, 50 μg ml^{-1} gentamicin. CLL 1465 fibroblasts were then cultured with LGL-derived IL-1 for 3 days[23]. Cultures were pulsed for the last 16 h with 1 μCi 3H-thymidine (1.9 mCi mM^{-1}). After treatment with trypsin–EDTA solution (0.5 mg ml^{-1} trypsin, 0.2 mg ml^{-1} EDTA, 37 °C, 10 min), cells were collected using an automated device. Results are expressed as the mean ± s.e.m. of triplicate cultures. This experiment was repeated twice with similar results.

To identify the cell subset which was responsible for the observed suppression, we treated LGL with anti-Leu-M1 + C and then either with anti-OKT4 (reactive with a helper T-cell subset[16] and 4–5% of LGL[3]) or anti-OKT8 (reactive with a suppressor T-cell subset[17] and 15–20% of LGL[3]) monoclonal antibodies and C. While removal of OKT4-positive cells had no effect (see Table 1), the IL-1 production was more than doubled by treating LGL with anti-OKT8 monoclonal antibody, suggesting that a population of OKT8$^+$ LGL and OKT8$^+$ lymphocytes may regulate the IL-1 production by LGL.

To identify the subset(s) of LGL producing IL-1, OKT3$^-$, Leu-M1$^-$, LGL were sorted by fluorescence-activated cell sorter (FACS) according to their reactivity with anti-OKT11 (ref. 3), anti-B73.1 (ref. 13), anti-OKM1 (ref. 18) or AF-10 (ref. 19; a monoclonal antibody specific from DR surface molecules on macrophages and B cells) + C. The results (Table 1) showed that the IL-1 production in response to LPS was predominantly attributable to a B73.1$^+$, OKM1$^+$, DR$^+$ subset of LGL, while the B73.1$^-$, OKM1$^-$, DR$^-$ cell subsets produced only a small level of IL-1 activity. The results also showed that both OKT11$^+$ and OKT11$^-$ subsets of LGL produced comparable levels of IL-1 activity.

Human LGL maintaining NK activity can be cultured for several weeks in lectin-depleted IL-2 containing medium[20]. LGL-enriched fraction 3 and T lymphocyte-enriched fraction 7 from discontinuous Percoll density gradients were cultured in IL-2-containing media for about 10 generations. These cultured LGL and T cells were stimulated with LPS, and IL-1 production was determined during a 2-day culture period. LGL cultured for up to 3 weeks maintained their NK activity as previously reported[20], as well as their capacity to produce consistently

significant levels of IL-1 activity in the absence of any contaminating monocytes (Table 1). In contrast, cultured T cells did not produce any detectable IL-1 activity and showed no significant NK activity.

In the LGL subset(s) reactive with anti-B73.1 or anti-OKM1 monoclonal antibodies, NK activity correlated with the levels of IL-1 production. The relationship of NK activity and IL-1 production of cells separated on the basis of reactivity with anti-OKT11 monoclonal antibody was evaluated. Both the $OKT11^+$ and $OKT11^-$ subsets of LGL secreted IL-1 and showed NK activity. In the case of AF-10, however, NK activity was nearly equally distributed in both the DR^- and DR^+ subsets of LGL as reported elsewhere[3], whereas the IL-1 production was limited to the DR^+ subset.

The IL-1 activity of supernatants from cultured LGL ($\sim 6 \times 10^7$) stimulated with LPS for 48 h was characterized biochemically by sequential $(NH_4)_2SO_4$ precipitation, Sephacryl S200 gel filtration and preparative isoelectrofocusing (IEF). IL-1 activity derived from cultured LGL eluted from S200 gel column in the range of 15,000 molecular weight (MW) and was heterogeneous on IEF with a major peak at a *p*I 6.8 and two minor peaks at *p*I 5.5 and 4.5 (Fig. 2). The IL-1 activity in supernatants derived from fresh LGL had almost identical characteristics (data not shown). These data are consistent with those reported for monocyte-derived human IL-1 (ref. 21).

Monocyte-derived human IL-1 has been reported to enhance the T-lymphocyte response to polyclonal stimulants such as phytohaemagglutinin A (PHA) in the apparent absence of macrophage accessory cells[22] and to stimulate human fibroblast proliferation[23]. Similarly, LGL-derived human IL-1 could replace the requirement of T-lymphocyte response to PHA as well as to stimulate the proliferation of CRL 1445 human fibroblasts (see Table 2).

IL-1 promotes the generation of cytotoxic effector cells[24], has a crucial role in T- as well as B-lymphocyte responses to antigens[25,26], stimulates fibroblast proliferation[23] and collagenase production[27], and induces fever[28] and production of acute phase proteins[29]. The evidence that LGL produce considerable IL-1 activity suggests that some immunological function(s) in addition to NK lytic activity may be exerted by a subset(s) of LGL. Indeed, we have obtained data showing that the IL-1-producing subset(s) of LGL, $OKM1^+$, DR^+, can also exert an effective accessory cell function for T-lymphocyte activation (data not shown).

In conclusion, our results show that LGL with NK activity can produce IL-1. They show further that IL-1 was secreted mainly by LGL bearing the $OKM1^+$ or $B73.1^+$ phenotypes, which are those highly associated with NK activity. Furthermore, preliminary studies showed that human LGL-derived clones, with $B73.1^+$ $OKM1^+$ phenotype had NK activity and also secreted IL-1, suggesting that these two functions may be carried out by the same cell. It has been reported that another subset(s) of LGL is capable of producing IL-2[5]. Thus, at least two functionally and phenotypically distinct subsets of LGL have been identified; our data also raise the possibility that a third subset, of $OKT8^+$ LGL, may participate in the negative regulation of IL-1 production by LGL.

We thank C. W. Reynolds and B. J. Mathieson for valuable discussion of the manuscript; J. Conlon and K. McNitt for help in statistical analysis of the data; G. Trinchieri for the gift of anti-B73.1 monoclonal antibody; and the NCI-FCRF Central Clerical Pool for secretarial assistance.

Mouse Ia antigens are receptors for lactate dehydrogenase virus

T. Inada & C. A. Mims

Department of Microbiology, Guy's Hospital Medical School, London SE1 9RT, UK

Infection of mice with lactate dehydrogenase virus (LDV) leads to elevation of plasma lactate dehydrogenase, lifelong viraemia and perturbations of cell-mediated and humoral immune responses. The virus replicates exclusively in a restricted set of macrophages[1,2], but the basis for restricted cell susceptibility is unknown. By immunofluorescence techniques we have found that the per cent infected was the same as the per cent expressing antigens encoded by the *I* region of the major histocompatibility complex (Ia). Infection of CBA strain $I\text{-}A^+$ peritoneal macrophages was blocked when cells were treated simultaneously with monoclonal antibody to I-A and I-E, but not with either antibody separately. LDV infectivity was inactivated when virus was treated with purified rat glycoprotein homologous to mouse I-A and I-E antigens. These results indicate that the receptors for LDV are I-A and I-E antigens. Selective infection of Ia-positive macrophages may have an important effect on the immunological capability of infected mice.

LDV (a strain received from Dr K. E. K. Rowson), in the form of serum taken 24 h after intraperitoneal (i.p.) infection of mice, was added to resident peritoneal macrophages of CD1 mice. Infected (antigen-containing) cells were scored by fluorescent antibody staining 10 h later. As the multiplicity of infection increased to 50 ID_{50}s (50% infectious dose) per cell, 4–10% cells became infected but this did not increase at 10,000 ID_{50}s per cell. Stueckmann *et al.*[3,4] have obtained similar results and also noted that it became progressively more difficult to infect peritoneal macrophages when they were maintained *in vitro* for longer than 24 h. Peritoneal macrophages are known to become Ia-negative after 1–2 days in culture[5].

Macrophages were obtained from various sites in CD1 mice and the percentage of cells supporting LDV replication and the percentage that were Ia-positive were determined (Table 1). Macrophages from all sites tested showed a close correlation between Ia positivity and susceptibility to LDV.

The expression of Ia antigens on macrophages can be regulated by prostaglandins of the E series[6]. Peritoneal macrophages

Table 1 Susceptibility to LDV infection and Ia positivity in macrophages from CD1 mice

Macrophage source	Ia-positive (%)	LDV-positive (%)
Peritoneal	5.5	4.9
Spleen	17.6	14.3
Liver	24.5	24.8
Thymus	65.2	61.0
Peripheral blood	6.7	5.9
Peritoneal macrophages from mice injected with indomethacin	25.8	23.5
Peritoneal macrophages from mice injected intraperitoneally with lymphokines	16.9	16.5

Spleen and thymus macrophages were obtained by mincing with forceps and lysing red cells with 0.83% NH_4Cl buffer. Liver macrophages were obtained by digesting with 0.05% collagenase. Peripheral blood monocytes were separated by Ficoll–Hypaque. Cells were incubated in minimal essential medium containing 10% fetal calf serum in 'ring' cultures at 37 °C with 5% CO_2 in air. After 3 h, cultures were washed vigorously to remove non-adherent cells, fixed for 10 min at 20 °C with 1% paraformaldehyde and the % Ia^+ cells determined by indirect fluorescent antibody staining with monoclonal antibody to I-A (OX6 used at 10 μg ml^{-1}). Other cells were infected with LDV at a multiplicity of infection of 10^4 ID_{50}s per cell. After 10–12 h, cultures were washed, dried, acetone-fixed and stained by the indirect fluorescent antibody technique for LDV antigens using mouse hyperimmune serum. The % of LDV-infected or Ia^+ cells was determined from examination of 20–50 fields, containing 500–1,000 cells, on each of 3–6 ring cultures. Counts on each ring culture varied by less than 20%. Each type of macrophage was obtained from a separate mouse or pool of mice and in repeat experiments the per cent Ia^+ and LDV-positive cells varied by up to twofold. In a given macrophage preparation, however, the % Ia^+ and LDV^+ were very similar.

were taken from mice that had received 50 μg indomethacin i.p. every 12 h for 72 h, and infected with LDV. The proportion of Ia-positive (Ia^+) cells was 25.8% and an equivalent number of cells were infected (Table 1). The percentage of Ia^+ cells was then increased by *in vivo* treatment with 0.1 ml of a 50% dilution of a 24-h supernatant from concanavalin A (Con A)-treated mouse spleen cell cultures; this was injected i.p. into mice every 12 h for 72 h and peritoneal cells were taken 12 h after the last injection. 16.7% of the cells were Ia^+ and 16.5% of the cells were infected. On the other hand, when peritoneal macrophages were maintained for 24 h *in vitro* before infection only 1–3% of the cells were Ia^+ and infectibility decreased likewise. A double labelling experiment was carried out in which peritoneal macrophages from normal CD1 mice were infected with LDV and stained for Ia and LDV antigens with rhodamine- and fluorescein-conjugated antibody after 7 h. The percentage of Ia^+ cells (11.0% at the initiation of infection) had decreased to 5.2% as a result of maintenance *in vitro* for 10 h; 6.1% of LDV-positive cells were now Ia-negative, but 84.6% of the remaining Ia-positive cells were LDV-positive.

The above observations show that the presence of Ia antigens in macrophages is correlated with susceptibility to LDV. This was investigated more directly by blocking infection with antibody to Ia antigens. Peritoneal macrophages from various strains of mice were treated with monoclonal antibodies that react with mouse I-A (OX6 and OX3; refs 7, 8) and with mouse I-E (H10-81.10; ref. 9), before infection with LDV. When antibody to I-A or I-E was used alone there was no influence on the virus-susceptibility of macrophages from CBA mice but there was a reduction in infection when monoclonal antibody OX6 (reacting with I-A on CBA macrophages) and antibody to I-E were added at the same time (Table 2). The monoclonal antibody OX6 does not react with BALB/c I-A, and in BALB/c macrophages the addition of monoclonal antibody to I-E fails to block LDV infectivity. I-E antigens are not expressed in *H-2b*, *H-2f* and *H-2q* mice[10] and in macrophages from C57BL/6 (*H-2b*) mice, monoclonal antibody to I-A (OX3) alone blocked the infectivity of LDV. An experiment with macrophages from I-E-negative congeneic mouse strains (Table 3), showed that the monoclonal antibody to I-A did not block LDV infection unless it reacted with macrophages[7]. As would be expected (data not shown), blocking was found to be less effective when a higher multiplicity of infection (500 ID_{50}s per cell) was used. Blocking of LDV infection was never complete, perhaps because large amounts of antibody are needed to block 100% of virus receptors on cells. Monoclonal antibody to mouse macrophages, or to mouse macrophage Fc receptors, failed to influence the LDV-susceptibility of peritoneal macrophages.

The results above were obtained by fluorescent antibody staining. On one occasion cultures were treated with actinomycin D, pulsed with tritiated uridine, and infected cells counted after

Resident peritoneal macrophages from C57BL/6, CBA and BALB/c mice were cultured in rings for 4–5 h after cell seeding. After removing non-adherent cells, macrophages were pretreated with monoclonal antibody to I-A (OX3, OX6), I-E (H10-81-10) or with a combination of anti-I-A and anti-I-E antibodies for 15 min at 20 °C. As controls, cells were treated in a similar way with rat monoclonal anti-mouse Fc receptor antibody (2-4G2), used as a culture supernatant[17,18] or anti-mouse macrophage antibody (F4/80) used as a concentrated culture supernatant[19]. After three washes with phosphate-buffered saline, the cells were infected with LDV at multiplicity of infection (MOI) = 50 at 37 °C for 40 min. The cultures were re-fed with minimal essential medium supplemented with 10% fetal calf serum and incubated for 8–10 h at 37 °C in 5% CO_2. The slides were then processed as described in Table 1, and LDV antigen-positive cells were counted in 1,000–2,000 cells on each of two rings. Per cent inhibition of infection was calculated as the difference between control and test divided by the control × 100. Each value represents the mean ± 1 s.e. from two experiments. *P* values were calculated by Student's *t*-test. Reactivity pattern of cells from different mouse strains with each monoclonal antibody was checked by indirect immunofluorescence. Anti-I-E antibody was used simultaneously with OX3 or OX6.

Peritoneal macrophages from I-E-negative mouse strains were treated with monoclonal antibody to I-A (OX6), infected with LDV and the results are expressed as % inhibition of infection as shown in Table 2. The reactivity pattern of cells with this antibody is shown as described elsewhere[7] and was confirmed by immunofluorescence staining. Each value is the mean ± 1 s.e. of four ring cultures.

Serial 10-fold dilutions of purified rat Ia antigens (homologous to mouse I-A and I-E antigen) and mouse Thy 1.2 antigen were incubated with LDV ($1\times10^7\ ID_{50}s\ ml^{-1}$) for 1 h at 4 °C, then added to C57BL/6 mouse peritoneal macrophages at a calculated MOI of 20 ID_{50}s per cell. LDV antigen-positive cells were counted in 1,000–2,000 cells for each of four ring cultures 10 h later. The data are presented as described in Table 2. The antigens were prepared by 2% deoxycholate extraction of spleen cells, affinity column purification with monoclonal antibodies, elution, and removal of deoxycholate by ethanol precipitation.

autoradiography[2]. Blocking of infection of CBA macrophages by anti-I-A plus anti-I-E antibody, but not by either antibody alone, was confirmed (data not shown).

In double-labelling experiments with fluorescein- and rhodamine-labelled antibody using rabbit antiserum to I-E and mouse monoclonal antibody to I-A, it was noted that I-A and I-E antigens were present on the same peritoneal macrophages. Rabbit anti-rat I-E antiserum plus complement was therefore used to lyse Ia-positive macrophages. With serum dilutions up to 1:100 there was a 10% reduction in cell numbers and a 90% reduction in susceptibility to LDV (data not shown).

Finally, a non-immunological method was used to show that Ia antigens are receptors for LDV. LDV was pre-treated with purified rat Ia antigens, either E or A type glycoprotein, which are homologous to mouse I-A and I-E antigens[8], then infectivity was assayed in C57BL/6 (I-E-negative) peritoneal macrophages (Table 4). At a calculated multiplicity of 20 ID_{50}s per cell, a dose-dependent significant inhibition of infection of macrophages was seen with dilutions of either antigen down to 1 $\mu g\ ml^{-1}$. Murine cytomegalovirus is another virus that infects only a minority of peritoneal macrophages[11] but this was not influenced by treating macrophages with antibody to Ia antigens, nor by treating the virus with Ia antigens (data not shown).

If Ia antigens function as receptors for LDV, the susceptibility of a subset of macrophages is accounted for. Stueckemann *et al.*[4] suggested that infected macrophages are eliminated, lifelong infection in mice being maintained by continuous production of fresh susceptible macrophages. This is explained if Ia-positive (virus-susceptible) macrophages are constantly generated. We have observed that the proportion of Ia-positive peritoneal macrophages is lower (1–3%) in persistently infected mice, suggesting selective loss of these cells.

Selective infection of Ia-positive, antigen-presenting cells might be expected to lead to perturbation of immune responses. If the cells that present viral antigen are at the same time the source of antigens, and are possibly damaged or destroyed, this could result in impaired immune responses to the infecting virus. Isakov *et al.*[12] reported impaired presentation of antigens by LDV-infected macrophages. Others have described enhanced antibody responses early after infection and depressed responses at a later stage, but the mechanisms are unclear[13]. Defects in cell-mediated responses have been described[14], and there is so far no evidence that mice develop cell-mediated immune responses to LDV.

It might have been expected that ubiquitous antigens encoded by the major histocompatibility complex would, on occasion, be used as receptors by an infecting virus but so far there has been little evidence for this. Mouse H-2 antigens can function as receptors for Semliki Forest virus[15] but these are not the only receptors because H-2-negative mouse cells can be infected with this virus[16]. Perhaps LDV can, on occasion, use non-Ia receptors.

The possibility that other Ia-positive cells, such as Langerhan's cells, B cells, dendritic cells and endothelial cells are also infected by LDV is being investigated.

We thank Dr Alan Williams for his help and gifts of purified rat Ia antigens, OX3 and OX6 monoclonal antibodies, and rabbit anti-Ia antiserum. We also thank Dr M. Pierres for anti-I-E monoclonal (H10-81.10; ref. 9) and Drs J. S. Porterfield and S. Gordon for monoclonal antibody (2.4G2 IgG) to Fc receptor (FcR 11)[17], originating from Dr Unkeless[18], and monoclonal antibody (F4/80) to mouse macrophages[19].

A synthetic peptide that is a bombesin receptor antagonist

R. T. Jensen, S. W. Jones, K. Folkers* & J. D. Gardner

Digestive Diseases Branch, National Institute of Arthritis, Diabetes, and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

The tetradecapeptide bombesin was originally isolated from frog skin[1]. Bombesin-like peptides have since been detected in mammalian gastrointestinal tract[2,3], brain[3,4] and lung[5,6]. These peptides have potent pharmacological effects on the central nervous system[7]; they cause contraction of intestinal, uterine and urinary tract smooth muscle[8]; and stimulate the release of other peptides including gastrin[2,3,9], cholecystokinin[9], motilin[9], pancreatic polypeptide[9], neurotensin[9], insulin[9,10], enteroglucagon[9,10], prolactin[11,12] and growth hormone[11,12]. Specific plasma membrane receptors for bombesin have been

demonstrated on pancreatic acinar cells[13], brain membranes[14] and pituitary cells[15]. Studies defining the physiological importance of bombesin have been impeded by the lack of a bombesin receptor antagonist. Here we describe experiments which demonstrate that a peptide originally described as a substance P receptor antagonist[16], [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]substance P, is also a bombesin receptor antagonist. This peptide competitively inhibits the ability of bombesin to stimulate enzyme secretion from dispersed pancreatic acini, and also inhibits the action of other peptides that interact with the bombesin receptor.

A recent study of the ability of analogues of substance P (SP) to act as specific, competitive substance P receptor antagonists, showed that high concentrations of one analogue, [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP, also inhibited bombesin-stimulated amylase release[17]. Because there are no known competitive inhibitors of bombesin, we investigated this inhibition in more detail, and now report that [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP is a bombesin receptor antagonist.

Dispersed acini from guinea pig pancreas were prepared as described previously[18,19]. Previous studies have shown that these acini possess specific, high-affinity plasma membrane receptors for bombesin[13], substance P[20], muscarinic cholinergic agents[21], cholecystokinin[22], vasoactive intestinal peptide (VIP)[21,23] and secretin[21,23,24]. The bombesin receptor interacts only with bombesin and structurally related peptides[13,21] (litorin, ranatensin, alytesin and gastrin-releasing peptide) and occupation of the bombesin receptor by any of these peptides causes mobilization of cellular calcium and stimulation of enzyme secretion[13,25,26].

Dispersed acini were suspended in a standard incubation solution containing 24.5 mM HEPES (*p*H 7.4), 98 mM NaCl, 6 mM KCl, 2.5 mM NaH_2PO_4, 5 mM sodium pyruvate, 5 mM sodium fumarate, 5 mM sodium glutamate, 2 mM glutamine, 16.5 mM glucose, 0.5 mM $CaCl_2$, 1.0 mM $MgCl_2$, 5 mM theophylline, 1% (w/v) albumin, 0.01% (w/v) trypsin inhibitor, 1% (v/v) amino acid mixture and 1% (v/v) essential vitamin mixture. The incubation solution was equilibrated with 100% O_2 and all incubations were performed with 100% O_2 as the gas phase.

Bombesin caused a 10-fold stimulation of amylase release (Fig. 1*a*). Detectable stimulation occurred with 0.03 nM bombesin, half-maximal stimulation with 0.16 nM bombesin and maximal stimulation with 1 nM bombesin. [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP in concentrations up to 100 μM did not stimulate amylase release but caused a parallel rightward shift in the dose–response curve for bombesin-stimulated amylase release (Fig. 1*a*). With increasing concentrations of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP, the magnitude of the rightward shift was proportional to the concentration of the peptide (Fig. 1*a*). When the data from Fig. 1*a* were plotted in the form of Schild[27], that is, log(dose ratio − 1) versus log antagonist concentration, the values could be described by a single regression line having a slope (and 95% confidence limits) of 1.00 (0.84–1.15) (Fig. 1*b*). These results demonstrate that in addition to being a competitive antagonist of the substance P receptor on these acinar cells[17], [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP is also a competitive antagonist of the bombesin receptor. The apparent affinity (and 95% confidence limits) of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP for the bombesin receptor calculated for bombesin-stimulated amylase release was 2.9 (0.7–12) μM. Previously, studies have demonstrated that bombesin and litorin have affinities for the bombesin receptor of 2 nM and 40 nM, respectively[13]; therefore, the apparent affinity of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP for the bombesin receptor is 1,500-fold lower than that for bombesin and 70-fold lower than that for litorin. The affinity of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP for the substance P receptor on pancreatic acini has been shown to be 0.65 μM[17]; thus, the substance P analogue has four times greater affinity for the substance P receptor than for the bombesin receptor.

[D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP inhibited the stimulation of amylase release by peptides that interact with the bombesin

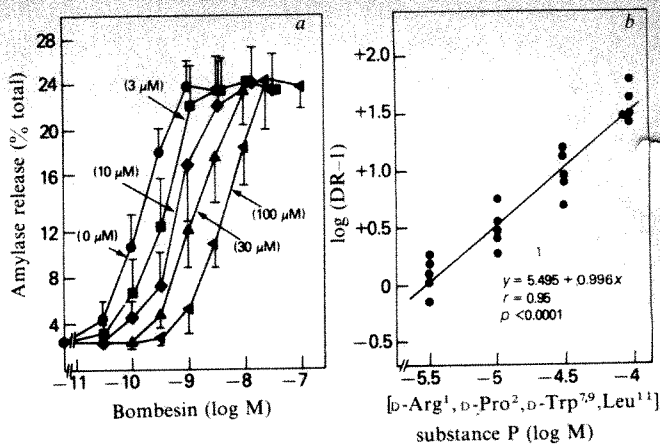

Fig. 1 Effect of various concentrations (shown in parentheses) of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP on bombesin-stimulated amylase release. *a*, Dispersed acini from guinea pig pancreas were incubated with 0, 3, 10, 30 or 100 μM [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP with the indicated concentration of bombesin. Amylase release was measured during a 30-min incubation at 37 °C as described previously[30] and is expressed as the percentage of the amylase in the acini at the beginning of the incubation, that is, the percentage of the total. In each experiment each value was measured in duplicate and results are the means from five separate experiments. Vertical bars represent 1 s.d. Data from the experiments shown in *a* were plotted in the form of Schild[27] (*b*). The best fit to the line was calculated by least-squares analysis. DR, the dose-ratio, which is the ratio of the dose of bombesin required to give half-maximal stimulation in the presence of a given concentration of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP to the dose required to give half-maximal stimulation in the absence of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP.

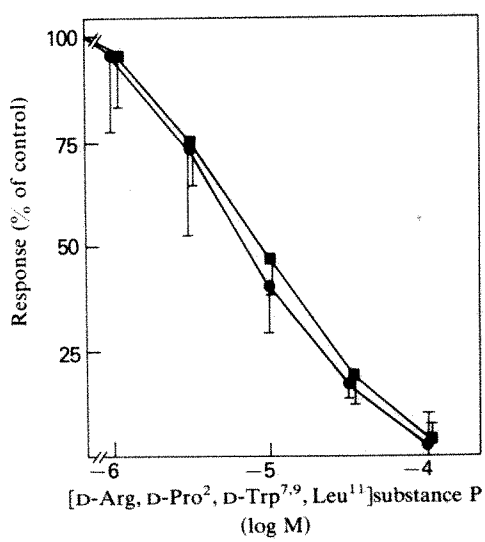

Fig. 2 Effect of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP on bombesin-stimulated amylase release (●) and on binding of ^{125}I-[Tyr[4]]bombesin (■). To measure amylase release, dispersed pancreatic acini were incubated with or without 0.3 nM bombesin plus the indicated concentrations of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP. Values for amylase release were calculated as the percentage of the increase caused by bombesin alone. To measure binding of ^{125}I-[Tyr[4]]bombesin, acini were incubated with 0.3 nM ^{125}I-[Tyr[4]]bombesin plus the indicated concentration of [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP. Saturably bound ^{125}I-[Tyr[4]]bombesin was determined after incubation at 37 °C for 30 min as described previously[12]. Values for ^{125}I-[Tyr[4]]bombesin bound are calculated as the percentage of radioactivity that was saturably bound in the absence of added [D-Arg[1], D-Pro[2], D-Trp[7,9], Leu[11]]SP. In each experiment each value was measured in duplicate and the results are the means of six separate experiments. Vertical bars represent 1 s.d.

receptor (bombesin, ranatensin, gastrin-releasing peptide, litorin and alytesin)[8,13], or by peptides that interact with the substance P receptor (substance P)[20] (Table 1). In contrast, [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP had no effect on stimulation caused by agents that interact with the cholecystokinin receptor (CCK-8), the cholinergic receptor (carbachol) and the vasoactive intestinal peptide receptor (VIP, secretin), or by the secretagogues 8-bromo-cyclic AMP and A23187 (Table 1).

To investigate directly the ability of [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP to interact with bombesin receptors on pancreatic acini, we measured its ability to inhibit binding of ^{125}I-[Tyr^4]bombesin and its ability to inhibit bombesin-stimulated amylase release in identical experimental conditions. For each function, the dose–inhibition curves were superimposable (Fig. 2). For both inhibition of binding of ^{125}I-[Tyr^4]bombesin and inhibition of bombesin-stimulated amylase release, [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP caused detectable inhibition at concentrations greater than 1 μM, half-maximal inhibition at 7.2 μM, and complete inhibition at 100 μM. These results demonstrate directly that [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP interacts with the bombesin receptor and that its ability to inhibit bombesin-stimulated amylase release can be accounted for entirely by its ability to interact with the bombesin receptor.

Table 1 Effect of [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP on the stimulation of amylase release by various pancreatic secretagogues

Secretagogue	Amylase release (% total)	
	Secretagogue alone	[D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP (30 μM)
None	2.6 ± 8.1	2.7 ± 1.2
Bombesin (0.3 nM)	17.5 ± 5.0	3.8 ± 1.2*
Ranatensin (0.3 nM)	20.6 ± 4.3	6.0 ± 2.4*
Gastrin-releasing peptide (1 nM)	18.8 ± 3.0	6.0 ± 2.4*
Litorin (1 nM)	24.6 ± 5.4	5.0 ± 1.9*
Alytesin (1 nM)	17.3 ± 5.2	4.2 ± 2.8*
CCK-8 (0.1 nM)	31.7 ± 4.7	30.0 ± 3.4
Carbachol (10 μM)	31.1 ± 5.0	29.2 ± 2.3
A23187 (5 μM)	14.0 ± 2.5	14.8 ± 1.2
VIP (3 nM)	26.8 ± 2.0	27.2 ± 2.4
Secretin (0.1 μM)	26.0 ± 3.5	26.3 ± 2.7
8-bromo-cyclic AMP (1 mM)	24.0 ± 4.0	25.6 ± 1.2
Substance P (3 nM)	7.4 ± 1.4	2.4 ± 0.6*

Dispersed acini from guinea pig pancreas were incubated for 30 min at 37 °C with various secretagogues alone or with [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP. In each experiment each value was determined in duplicate and results are the means ± 1 s.d. from four separate experiments. CCK-8, the COOH-terminal octapeptide of cholecystokinin.

* Significantly different ($P < 0.01$) from the value obtained with the secretagogue alone by Student's paired t-test.

The apparent affinity of [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP for the bombesin receptor is much greater than that of substance P, because the latter, at concentrations as high as 30 μM, does not interact with bombesin receptors on pancreatic acini (data not shown). In contrast, the affinity of [D-Arg^1, D-Pro^2, D-Trp^{7,9}, Leu^{11}]SP for the substance P receptor on pancreatic acini is 2,500-fold lower than that of substance P[17]. Thus, modifying substance P by substitutions in positions 1, 2, 7, 9 and 11 increases the affinity of the peptide for bombesin receptors but decreases the affinity of the peptide for substance P receptors.

Several different analogues of bombesin have been tested and found not to inhibit the action of bombesin[28,29]. Our present finding that an analogue of substance P can function as a bombesin receptor antagonist raises the possibility that appropriate modifications of the bombesin molecule may give rise to a peptide that will function as a bombesin receptor antagonist without also interacting with the substance P receptor.

We thank Mary O'Shaughnessy for preparing the manuscript for publication and the Robert A. Welch Foundation for partial support of this research.

The second messenger linking receptor activation to internal Ca release in liver

The increase in cytosolic [Ca^{2+}] induced by Ca-mobilizing hormones in liver is mainly due to release of Ca from intracellular stores[1–7]. For Ca to be released from internal sites a messenger must be formed at the plasma membrane which diffuses into the cytosol to signal Ca release from the intracellular organelles[2,3,7,8]. One of the first actions of these hormones is to cause breakdown of the polyphosphoinositides to form soluble inositol phosphates[9–11]. Some evidence for the idea that these substances could be the second messenger[10] has been obtained in pancreatic acinar cells[12]. Here we have found that hormone activation of hepatocytes causes rapid breakdown of phosphatidylinositol 4,5-bisphosphate [PtdIns(4,5)P_2] to form inositol trisphosphate ($InsP_3$). When applied to permeabilized hepatocytes, $InsP_3$ releases Ca from non-mitochondrial ATP-dependent pools. This suggests that $InsP_3$ could be the messenger linking Ca-mobilizing receptor activation to intracellular Ca release in liver.

Isolated hepatocytes were prepared by collagenase digestion of the livers of male guinea pigs and used either intact or after

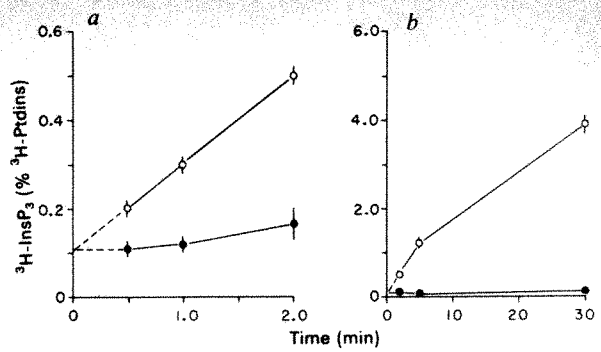

Fig. 1 Formation of ^{3}H-InsP$_3$ in guinea pig hepatocytes over 0–2 min (*a*) or 0–30 min (*b*). Freshly prepared guinea pig hepatocytes[17] were incubated in Eagle's medium with 2% bovine serum albumin (BSA) with 5 μCi ml^{-1} (three experiments) or 20 μCi ml^{-1} (three experiments) of ^{3}H-inositol, and containing 0.1 μM angiotensin II for 60 min. The cells were washed by slow centrifugation and resuspended in Eagle's medium with 2% BSA. After 5 min, 10 mM LiCl was added to block inositol 1-phosphate phosphatase[24]. In two preliminary experiments, LiCl had no discernible effect on ^{3}H-InsP$_3$ accumulation. Five minutes later, adrenaline (0.1 mM, with 10 μM (+)propranolol) was added (○); control, ●. Aliquots of the suspension were taken at various times as indicated, and were rapidly precipitated with 4.5% perchloric acid. The *p*H of the supernatant was adjusted to 8–9 with sodium borate buffer and radioactive fractions associated with specific inositol phosphates were separated by anion exchange as described previously[14,20]. For each experiment, total lipid radioactivity (almost exclusively PtdIns) was determined in two chloroform–methanol extracts, one taken just before the addition of adrenaline and one just after the last sample was taken. The radioactivity in these samples did not change significantly over the course of the experiments, nor did total tissue content of PtdIns, determined as described previously[21]. For each experiment, the cpm of ^{3}H-InsP$_3$ was expressed as a percentage of the c.p.m. of ^{3}H-PtdIns (that is, the chloroform–methanol extract). In the 5 μCi ml^{-1} experiments, samples were taken at 5 and 30 min and PtdIns radioactivity averaged 84,000 ± 9,000 c.p.m. per mg DNA; in the 20 μCi ml^{-1} experiments, samples were taken at 0.5, 1, 2 and 30 min and PtdIns radioactivity averaged 544,000 ± 30,000 c.p.m. per mg DNA. All of the data points in Fig. 1 are thus means (±s.e.m.) of three determinations except at $t = 30$ min which is the mean (±s.e.m.) of six experiments. In the latter case, the three experiments with 5 μCi ml^{-1} ^{3}H-inositol gave a value of 4.1 ± 0.3% while the 20 μCi ml^{-1} experiments gave a value of 3.7 ± 0.3%, the two not differing significantly.

permeabilization of their plasma membranes with saponin, as previously described[13]. The intact hepatocytes were incubated in Eagle's medium, while the permeable cells were incubated in a medium with high [K$^+$], low [Na$^+$], ATP (1.5 mM) and an ATP-regenerating system (see Fig. 2 legend for details). Ca-EGTA buffers were used to give free Ca^{2+} concentrations of either 180 nM or 3.3 μM (ref. 13). Formation of ^{3}H-inositol phosphates by hepatocytes preincubated with ^{3}H-inositol was measured as described previously[14].

Intact guinea pig hepatocytes showed a rapid increase in radioactivity associated with InsP$_3$ on α-adrenoceptor activation (Fig. 1). To test the hypothesis that InsP$_3$ is capable of releasing internal Ca we used a permeabilized hepatocyte preparation the characteristics of which have been described in detail elsewhere[13]. In experiments summarized in Fig. 2*a*, permeable hepatocytes were incubated in a medium with [Ca^{2+}] buffered to 180 nM in the presence of tracer quantities of ^{45}Ca. This value for [Ca^{2+}] was chosen because in these conditions the levels of phosphorylase *a*, the uptake of ^{45}Ca and the content of ^{40}Ca in saponin-treated cells were found to be similar to those in intact hepatocytes. We therefore concluded that the cytosolic [Ca^{2+}] in an intact hepatocyte is close to 180 nM[13]. Recent estimates of intracellular [Ca^{2+}] in rat[15] and guinea pig[13] hepatocytes by using the intracellular Ca-indicator 'quin-2' (ref. 16) confirm this estimate.

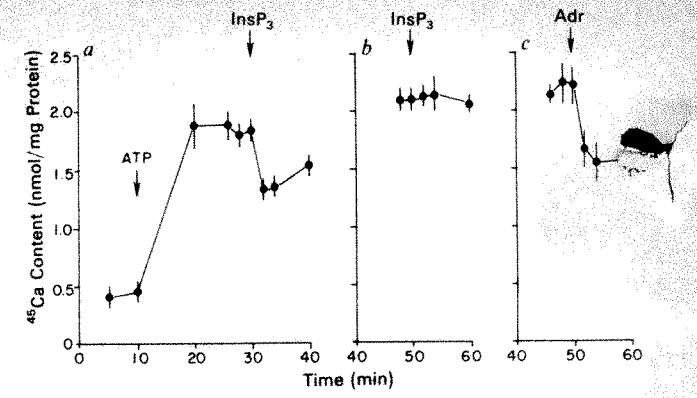

Fig. 2 *a*, The effect of InsP$_3$ (5 μM) on the ^{45}Ca content of saponin-treated hepatocytes. *b*, InsP$_3$ (5 μM) had no effect on the ^{45}Ca content of normal guinea pig hepatocytes; *c*, adrenaline (5 μM in the presence of 10 μM (+)propranolol) caused a net loss of ^{45}Ca from normal hepatocytes. In *b* and *c* the normal hepatocytes were loaded with ^{45}Ca for ~45 min (which is long enough to allow most of the intracellular Ca to exchange[13]).
Methods: At time zero ^{45}Ca was added to a suspension of saponin-treated hepatocytes incubated in a cytoplasmic-type medium[13] of the following composition (mM): NaCl, 20.0; KCl, 100; $MgSO_4$, 5.0; NaH_2PO_4, 0.96; $NaHCO_3$, 25; EGTA, 1.0, at *p*H 7.2 and 37 °C. The medium also contained albumin (2%), antimycin (10 μM) and an ATP-regenerating system consisting of creatine phosphate (5 mM) and creatine phosphokinase (5 U ml^{-1}). The [Ca^{2+}] was set at 180 nM which is believed to be [Ca^{2+}]$_i$ in a normal unstimulated guinea pig hepatocyte[13]. At 10 min, ATP (1.5 mM) was added and there was a rapid uptake of ^{45}Ca by the cells, which reached steady state by 20 min. At this [Ca^{2+}] the ATP-dependent ^{45}Ca uptake into the saponin-treated cells was insensitive to a combination of the mitochondrial poisons 2,4-dinitrophenol (0.5 mM) and oligomycin (10 μM) and is believed to be taken up mainly into the endoplasmic reticulum[13]. At 30 min, InsP$_3$ (5 μM in H_2O) was added and there was a loss of ~25% or ~0.5 nmol per mg protein of the cell ^{45}Ca content. An equivalent volume of H_2O alone had no effect on the ^{45}Ca content (not shown). ^{45}Ca content was determined in all experiments by centrifugation through ice-cold sucrose and EGTA as described previously[25]. Data were averaged ($n = 5$ in *a*, 3 in *b* and 4 in *c*) and the bars represent the s.e.m. InsP$_3$ (specifically inositol(1,4,5)trisphosphate) was prepared from human red blood cell ghosts essentially by the method of Downes *et al.*[26], the only major modification being that the rejuvenation of the red blood cells before lysis was carried out in a chloride-free medium (the chloride being replaced by citrate[26,27]). InsP$_3$ was separated on Dowex formate columns[14], and desalted by elution from a Dowex chloride column by 1 M LiCl. After addition of 100 μg mannitol, the extract was dried *in vacuo*, before removal of the LiCl with ethanol. Some of the InsP$_3$ was further purified by high-voltage ionophoresis in pyridine/acetic acid (*p*H 3.6) for 1.5 h at 40 V cm^{-1}. The InsP$_3$ was eluted from the paper, and the adjacent strip of paper was also eluted as a control. For experiments not shown here, but described in the text, inositol 1,4-bisphosphate [Ins(1,4)P$_2$] was prepared from ox brain phosphatidylinositol 4-phosphate by strong alkaline hydrolysis, and purified by paper chromatography[14]. Inositol 1-phosphate (Ins1P) and inositol 1,2-cyclic phosphate were prepared enzymatically from yeast phosphatidylinositol and purified by ionophoresis[28,29].

On addition of ATP, the permeable cells accumulated ^{45}Ca rapidly to a level of about 2 nmol per mg protein (Fig. 2*a*). Once a steady state had been achieved the addition of 5 μM InsP$_3$ to these permeable cells caused a rapid (<2 min) net release of about 0.5 nmol per mg protein of cell-associated ^{45}Ca. This fairly closely approximates the quantity of Ca initially released from intact guinea pig hepatocytes by α-adrenergic stimuli (Fig. 2*c* and ref. 17). In two experiments (not shown), 5 μM of the InsP$_3$ which was purified by high-voltage ionophoresis (see Fig. 2 legend) induced a similar release of ^{45}Ca from the saponin-treated cells, but the eluate from the adjacent strip of paper had no effect. However, 5 μM InsP$_3$ did not cause ^{45}Ca release from intact hepatocytes (Fig. 2*b*), nor

did Ca-mobilizing hormones release Ca from permeable cells (not shown). $InsP_3$ had no effect on the ATP-independent ^{45}Ca associated with the permeable cells. Inositol 1,2-cyclic phosphate (5 μM) (previously proposed as a second messenger[18]), $Ins(1,4)P_2$ (up to 10 μM), Ins1P(5 μM) and inositol (5 μM) had no effect on the ^{45}Ca accumulated in an ATP-dependent manner by permeable hepatocytes (not shown).

Figure 3 shows the concentration dependence of the response of the permeable cells to $InsP_3$ in causing the net release of ^{45}Ca which had been accumulated in an ATP-dependent manner. The EC_{50} value for this effect was 0.22 μM, and it was maximal at 5 μM.

It has previously been demonstrated that with $[Ca^{2+}]$ in the medium buffered to 180 nM, uptake of ^{45}Ca and cellular content of total Ca in permeable hepatocytes are unaffected by the mitochondrial poisons 2,4-dinitrophenol and oligomycin[13]. The ^{45}Ca released by $InsP_3$ (Fig. 2*a*) must therefore come from ATP-dependent stores other than the mitochondria, the predominant component of which is likely to be the endoplasmic reticulum[3]. To determine whether $InsP_3$ is also capable of releasing Ca from the mitochondria, the experiment in Fig. 2*a* was repeated but with the permeable cells suspended in a medium with $[Ca^{2+}]$ buffered to 3.3 μM. In these conditions a considerably larger quantity of ^{45}Ca accumulates (Fig. 4). The uptake of this ^{45}Ca can be largely blocked by dinitrophenol and oligomycin and is therefore presumed to be primarily mitochondrial[13]. As shown in Fig. 4, 5 μM $InsP_3$ produced no significant release of ^{45}Ca from the cells when $[Ca^{2+}]$ in the medium was 3.3 μM, and we conclude that mitochondrial Ca is not released by $InsP_3$, at least in these conditions and with these concentrations of Ca^{2+} and $InsP_3$. The release of the 0.5 nmol per mg protein of ^{45}Ca from the endoplasmic reticulum pool by $InsP_3$, observed at 180 nM $[Ca^{2+}]$ (Fig. 2*a*), would not be statistically detectable here because of the higher ^{45}Ca content.

These findings comprise strong evidence that $InsP_3$ could function as a second messenger linking hormone receptor activation to internal calcium release in the liver. An important question is whether the intracellular level of $InsP_3$ is elevated sufficiently during hormonal activation for it to perform this Ca-mobilizing function. Although there is no adequately sensitive and specific method for measuring the chemical levels of inositol phosphates, they can be estimated if an assumption is made regarding specific radioactivities. Since the monoester phosphates of the polyphosphoinositides turn over much more rapidly than other parts of the molecules (refs 8, 19 and unpublished observations), it is reasonable to assume that in cells labelled with ^3H-inositol the specific radioactivities of the three phosphoinositides and thus also their breakdown products, the inositol phosphates, will all be similar[20]. In each of the experiments shown in Fig. 1, therefore, the radioactivity associated with phosphatidylinositol (PtdIns) (which did not change appreciably during the experiments and was not significantly altered by hormones) was measured and the radioactivity associated with $InsP_3$ expressed as a percentage of that value. From these data, and the knowledge that guinea pig hepatocytes contain 37.1 ± 2.7 ($n = 5$) nmol per mg protein (assayed as described previously[21]) of PtdIns, the cellular content of $InsP_3$ could be calculated. Assuming that hepatocytes contain 2.2 μl cell water per mg protein[6], the net increase in cellular $InsP_3$ induced by a maximal concentration of adrenaline was estimated to be about 16 μM at 30 s, 32 μM at 1 min and 53 μM at 2 min. As the α-adrenoceptor-induced release of ^{45}Ca from isolated intact guinea pig hepatocytes is not maximal until 2 min (see Fig. 2 and ref. 17), the $InsP_3$ would seem to be formed rapidly enough to act as a second messenger.

When applied to permeable cells in concentrations even lower than these estimated values, and with free $[Ca^{2+}]$ buffered to a level similar to that in the cytosol, $InsP_3$ induced the release of Ca from an intracellular store. Further, the quantity of Ca was similar to that released from the intracellular stores of intact hepatocytes by hormones. These results also support the view[13] that the primary source of hormone-sensitive Ca in the liver is a non-mitochondrial pool, perhaps the endoplasmic reticulum.

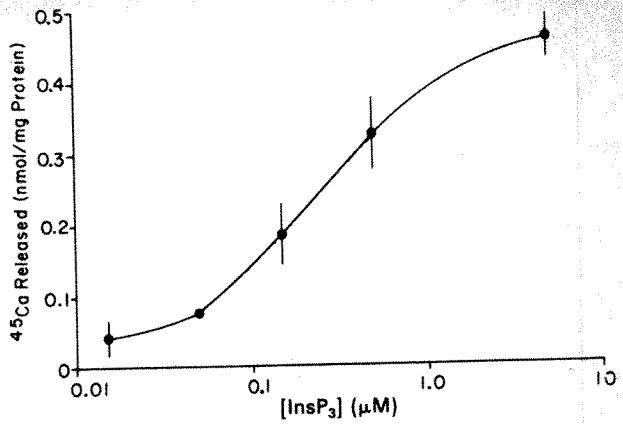

Fig. 3 The concentration–effect relationship for the ability of $InsP_3$ to release ^{45}Ca from permeable hepatocytes. Experiments were carried out as described for Fig. 2*a* and the amount of ^{45}Ca released was determined at 2 min by which time the effect was maximal. ^{45}Ca contents were determined by the rapid dilution of 100-μl aliquots of cell suspension in 10 ml of ice-cold isotonic sucrose containing 4 mM EGTA and tracer amounts of ^3H-sucrose for determination of trapped volume. The sample was then filtered rapidly through GF/C filters, washed with 10 ml of ice-cold isotonic sucrose, and the filters were counted for radioactivity. Data were averaged and the bars indicate s.e.m. for between three and five observations except at 5 μM where $n = 13$ and which includes data for which the ^{45}Ca content was determined by centrifugation[25] (from Fig. 2*a*).

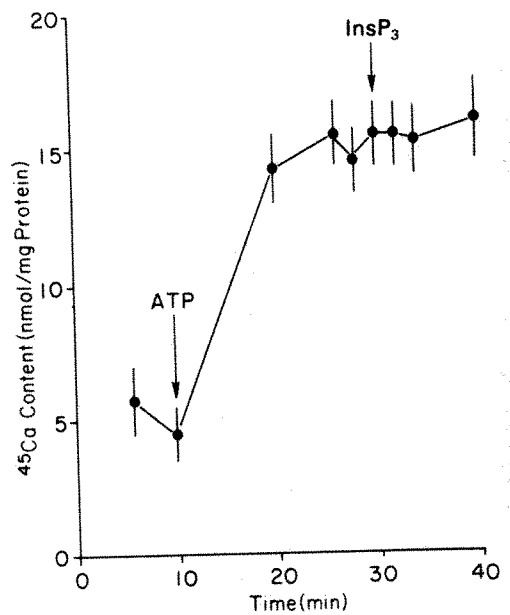

Fig. 4 Effect of $InsP_3$ (5 μM) on the ^{45}Ca content of saponin-treated guinea pig hepatocytes. The saponin-treated hepatocytes were incubated as described for Fig. 2*a* except that the $[Ca^{2+}]$ of the cytoplasmic-type medium was increased to 3.3 μM, a concentration at which there is substantial 2,4-dinitrophenol (0.5 mM)-and oligomycin (10 μM)-sensitive ^{45}Ca uptake, presumably by the mitochondria[13]. The ATP-dependent ^{45}Ca uptake was much greater than in Fig. 2*a* and as the endoplasmic reticulum mechanism saturates at about 3 nmol per mg protein[13], most of the uptake is ATP-dependent uptake into mitochondria. Application of $InsP_3$ had no effect on the ^{45}Ca content of the cells. Data were averaged and the bars indicate s.e.m. of three observations.

In the liver, as in many other tissues, agonist-induced release of intracellular Ca is accompanied by an increased membrane permeability to Ca (ref. 6). Following inositol lipid breakdown, the resulting diacylglycerol is rapidly phosphorylated to phosphatidic acid which it has been suggested may mediate Ca entry by functioning as a Ca-ionophore (ref. 22 but see ref. 23).

Although not addressed specifically by these studies, the possibility must now be considered that $InsP_3$ could also regulate plasma membrane permeability to Ca by the same, as yet unknown, mechanism involved in the release of intracellular Ca.

Cyclic nucleotides control a system which regulates Ca^{2+} sensitivity of platelet secretion

D. E. Knight* & M. C. Scrutton

Departments of Physiology* and Biochemistry, Kings College, The Strand, London WC2 2LS, UK

Cellular responses to extracellular signals are mediated by changes in the intracellular concentrations of one or more second messengers[1]. In platelets, inhibitory agonists increase intracellular cyclic-3′,5′-AMP ([cyclic AMP]$_i$ (refs 2, 3)) whereas excitatory agonists increase [Ca^{2+}]$_i$ and/or [1,2-diacylglycerol]$_i$ (refs 4–9), and in some cases decrease [cyclic AMP]$_i$ (refs 10, 11). Both activation and inhibition of platelet responses have been attributed to an increase in [cyclic-3′,5′-GMP]$_i$ (refs 8, 12). The activity of protein kinase C, which is associated with the platelet secretory response, is increased by both 1,2-diacylglycerol and Ca^{2+} (refs 4, 7, 8). The role of cyclic AMP may involve either inhibition of Ca^{2+} mobilization to the cytosol[13] or stimulation of intracellular Ca^{2+} uptake[14], and in addition inhibition of 1,2-diacylglycerol formation[15,16]. The relationship between cyclic-3′,5′-GMP (cyclic GMP) and other second messengers in platelet activation has not been defined. Using platelets made permeable by exposure to an intense electric field[17,18], we demonstrate here modulation of the Ca^{2+} sensitivity of platelet secretion by thrombin, and by 12-*O*-tetradecanoylphorbol-13-acetate (TPA) and 1-oleyl-2-acetylglycerol (OAG), both potent activators of protein kinase C. The effect of thrombin is selectively modified by cyclic GMP and cyclic AMP. The response to OAG and TPA is also modulated by cyclic AMP but to a much lesser extent.

An increase in [Ca^{2+}]$_i$ has previously been shown to induce ^{14}C-serotonin secretion from permeabilized platelets[19]. Addition of thrombin or a synthetic activator of protein kinase C such as OAG[20] or TPA[21,22], increases the sensitivity of the secretory response to Ca^{2+} by shifting the dose–response curve to the left (Fig. 1). In addition, thrombin, TPA and OAG cause a small increase in the extent of secretion at 1 nM Ca^{2+}. Although this increase could indicate the existence of a secretory mechanism which is not controlled by Ca^{2+} (refs 6, 7), its contribution to the overall secretory response is minimal in the conditions used here. Since both TPA and OAG mimic the effect of thrombin (Fig. 1), these data strongly support the proposed role of protein kinase C in amine storage granule secretion[7,8]. A similar increase in the sensitivity of the secretory

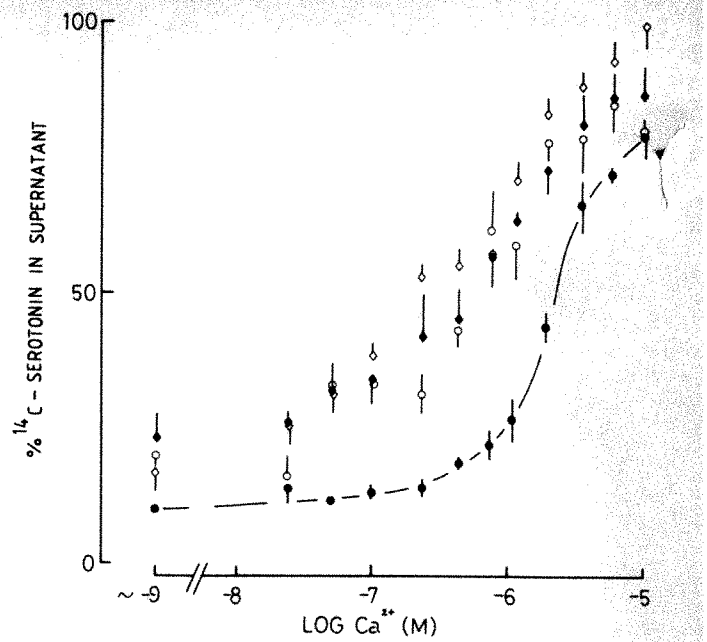

Fig. 1 The Ca^{2+} sensitivity of ^{14}C-serotonin secretion from platelets in the absence (●) and in the presence of thrombin (◇), OAG (○) or TPA (◆). Human platelets were prepared in the presence of 0.1 mM acetysalicylate as described previously[18], and were suspended in medium containing (in mM): glycine, 280; K-glutamate, 10; ATP, 5; Mg-acetate, 7; PIPES, 20; EGTA, 1; *p*H 6.7. The platelets were rendered permeable by 10 exposures to an intense electric field (20 kV cm^{-1}, $\tau \sim 30$ μs)[17]. After incubation for 15 min at 22 °C, 1-ml aliquots of the suspension (~2×10^8 cells ml^{-1}) were added to Ca-EGTA buffers and exactly 40 s later 0.2-ml aliquots of these Ca-challenged cells were added to 0.02 ml of thrombin, OAG, TPA or a control suspending medium. The final concentrations of EGTA, thrombin, OAG and TPA in the cell suspension were 16 mM, 0.5 U ml^{-1}, 30 μg ml^{-1} and 10 ng ml^{-1}, respectively. After incubation for 5 min at 22 °C the platelets were removed by centrifugation at 8,000*g* for 2 min and 0.05-ml aliquots of the supernatant fraction assayed for ^{14}C content by liquid scintillation counting. The time taken to challenge the cells with all the Ca buffers was 10 min, with the order of Ca^{2+} challenges being random. The ordinate shows the amount of ^{14}C in the supernatant fraction expressed as a percentage of the total ^{14}C measured by counting aliquots of the cell suspension. The data points refer to the mean of four determinations with the bar showing the s.e.m. OAG and TPA were prepared as stock solutions (60 mg ml^{-1} and 10 μg ml^{-1}, respectively) in dimethyl sulphoxide (DMSO), dispersed in the suspending medium by sonication under N_2 for 5 s, then diluted appropriately in that medium. The final concentration of DMSO in the cell suspension was 0.1% (v/v); control experiments showed that this level of DMSO had no effect on the secretory response and that addition of thrombin, OAG and TPA caused no significant increase in the extent of cellular lysis as measured by release of lactate dehydrogenase. Ca^{2+} concentrations were calculated using equilibrium constants of $10^{-6.127}$M (Ca-EGTA), $10^{-1.362}$M (Mg-EGTA), $10^{-3.50}$M (Ca-ATP) and $10^{-3.64}$M (Mg-ATP)[34]. The EC_{50} value for Ca^{2+} is 2.0 μM in the absence of other additions and 0.3–0.5 μM in the presence of 0.5 U ml^{-1} thrombin, 10 ng ml^{-1} TPA or 30 μg ml^{-1} OAG.

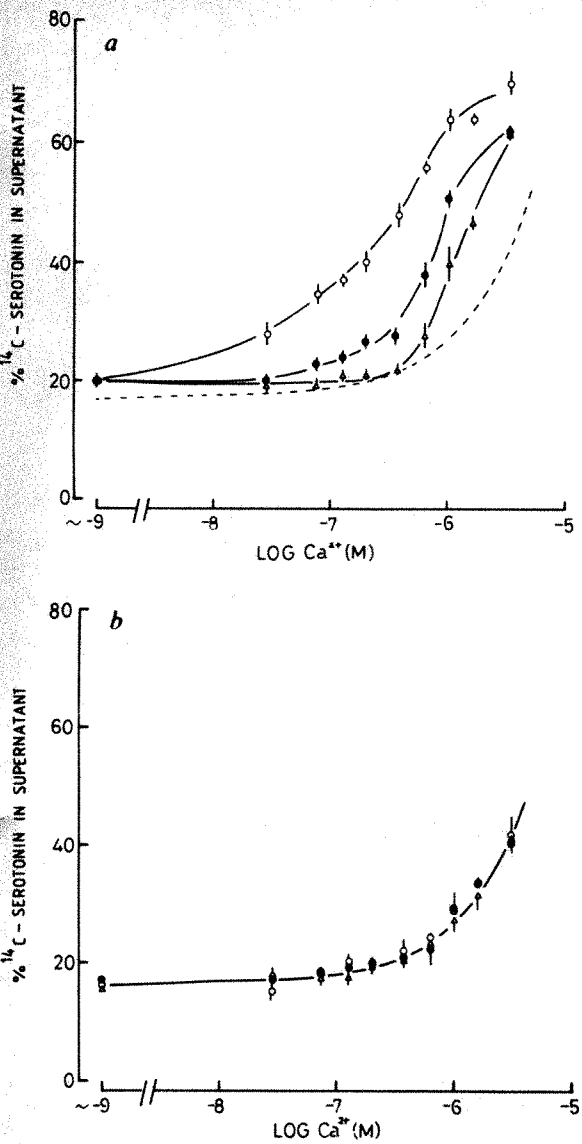

Fig. 2 The effect of cyclic AMP and cyclic GMP on the Ca^{2+} sensitivity of ^{14}C-serotonin release in the presence (*a*) or absence (*b*) of thrombin. Platelets were prepared and rendered permeable as described for Fig. 1 except that the suspending medium contained 1 mM ATP, 3 mM Mg-acetate, 0.5 mM EGTA and at a *p*H of 6.6. After incubation for 25 min at 22 °C, aliquots of the permeabilized suspension ($\sim 4 \times 10^8$ cells ml^{-1}) were incubated for 5 min at 22 °C with 0.2 μM 3-isobutyl-1-methylxanthine (IBMX) and 1 mM bis(*O*-aminophenoxy)ethane-*N*,*N*,*N*′,*N*-tetraacetic acid (BAPTA) either alone (●), in the presence of 20 μM cyclic AMP (△) or in the presence of 20 μM cyclic GMP (○). 0.1-ml aliquots of these suspensions were added to 0.1 ml of the suspending medium containing Ca-EGTA buffers either alone (*b*) or in the presence of thrombin (*a*). The final concentrations of EGTA and thrombin were 20 mM and 0.5 U ml^{-1}, respectively. The system was incubated for 5 min at 22 °C, centrifuged and the supernatant fraction assayed for ^{14}C content as described for Fig. 1. Data points refer to the mean of four determinations with the error bars showing the s.e.m. When Ca-EGTA buffers were added to the cell suspension containing BAPTA, the *p*H increased from 6.6 to 6.7. The Ca^{2+} concentrations stated above were calculated from the Ca-EGTA stability constants at these *p*Hs[34], and from the stability constants for Ca-BAPTA and Mg-BAPTA of $10^{-6.959}$ M and $19^{-1.77}$ M, respectively[35]. The curve drawn through the data points of cells incubated in the absence of thrombin (*b*) is also included as a dashed line in *a* to facilitate comparison with the data obtained in the presence of thrombin ± the cyclic nucleotides. The EC_{50} values for Ca^{2+} obtained from these data are 2.0 μM (no additions), 0.5 μM (in the presence of 0.5 U ml^{-1} thrombin), 1.2 μM (in the presence of 0.5 U ml^{-1} thrombin + 20 μM cyclic AMP) and 0.15 μM (in the presence of 0.5 U ml^{-1} thrombin + 20 μM cyclic GMP).

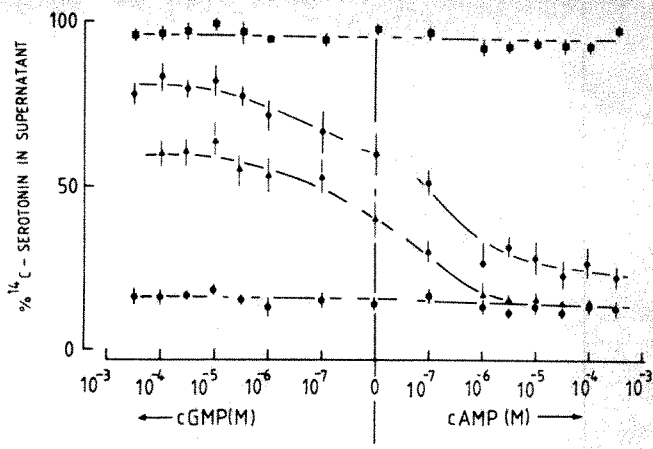

Fig. 3 Dose–response curves for the effects of cyclic AMP and cyclic GMP on ^{14}C-serotonin secretion mediated by thrombin in the presence of four fixed Ca^{2+} concentrations. Platelets were prepared and suspended in the medium described for Fig. 1 except that 1 mM BAPTA was added instead of 1 mM EGTA, and the *p*H of the medium was 6.6. The cells were rendered permeable as described for Fig. 1, then incubated for 8–10 min at 22 °C and at a cell density of 4×10^8 cells ml^{-1} in the presence of 5 μM IBMX and at concentrations of either cyclic AMP or cyclic GMP as shown. 0.1-ml aliquots of these suspensions were then added to 0.1 ml of the suspending medium containing thrombin and Ca-EGTA buffers to give final Ca^{2+} concentrations (calculated) of ~1 nM (●), 0.15 μM (▲), 0.5 μM (◆) and 5.0 μM (■). The final concentrations of thrombin and EGTA were 0.7 U ml^{-1} and 7.7 mM, respectively. After incubation for 5 min at 22 °C the platelets were removed and the supernatant fraction assayed for ^{14}C content as described for Fig. 1. The data points are the mean of four determinations, with error bars showing the s.e.m. The final Ca^{2+} concentrations were calculated as described for Fig. 2. No significant enhancement of the response was observed at 0.15 μM or 0.5 μM Ca^{2+} when 20 μM cyclic-2′3′-GMP was used in place of cyclic-3′5′-GMP.

response to Ca^{2+} has been observed on addition to TPA to permeabilized adrenal medullary cells[23]. The data also explain the previously reported[24] difference in secretory behaviour between intact and permeabilized platelets, and implicate 1,2-diacylglycerol as the factor responsible for the enhancement by thrombin of ^{14}C-serotonin secretion[25]. Production of 1,2-diacylglycerol on stimulation by thrombin has been observed in both intact[9] and permeabilized (R. J. Haslam, personal communication) platelets, although in the latter preparation the expected phosphoinositide breakdown[26] has not yet been demonstrated[27].

Addition of 20 μM cyclic AMP or cyclic GMP has no significant effect on the dose–response curve for ^{14}C-serotonin secretion induced by addition of Ca^{2+} when added alone (Fig. 2*b*). However, in the presence of thrombin (Fig. 2*a*), addition of 20 μM cyclic AMP depresses the response to a level approaching that observed in the presence of Ca^{2+} alone by shifting the dose–response curve to the right, whereas addition of 20 μM cyclic GMP enhances the response to Ca^{2+} by shifting the dose–response curve to the left (Fig. 2*a*). Dose–response curves obtained for the effects of cyclic AMP and cyclic GMP determined in the presence of thrombin and at four fixed calculated Ca^{2+} concentrations (Fig. 3) provide further evidence for specificity. Neither cyclic nucleotide has any significant effect at very low or saturating Ca^{2+} concentration where addition of thrombin causes little, if any, increment in ^{14}C-serotonin secretion (Figs 1, 3). At intermediate Ca^{2+} concentrations the presence of cyclic AMP markedly inhibits ^{14}C-serotonin secretion, with half-maximal inhibition obtained at or below 10^{-6} M (Fig. 3) whereas addition of cyclic GMP enhances ^{14}C-serotonin secretion with an EC_{50} in the micromolar range (Fig. 3). This effect of cyclic-3′5′-GMP is not mimicked by addition of cyclic-2′3′-GMP (Fig. 3 legend).

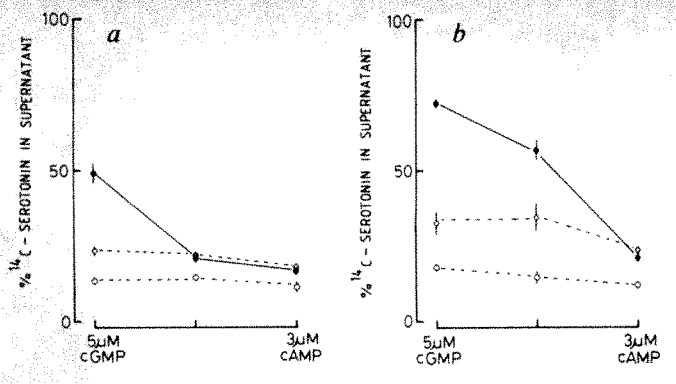

Fig. 4 Effect of raising the OAG and thrombin concentrations at fixed calculated Ca^{2+} concentrations of 0.17 μM (*a*) and 0.4 μM (*b*) in the presence and absence of cyclic AMP and cyclic GMP. Platelets were prepared and rendered permeable as described for Fig. 2. After incubation for 25 min at 22 °C the permeabilized platelet preparations ($\sim 3 \times 10^8$ cells ml^{-1}) were incubated for a further 5 min at 22 °C with 20 mM Ca-EGTA buffers corresponding to 0.17 μM Ca^{2+} (*a*) and 0.4 μM Ca^{2+} (*b*). 1.2-ml aliquots of the cell suspensions were then incubated for a further 5 min at 22 °C with 0.2 μM IBMX in the absence or presence of 3 μM cyclic AMP or 5 μM cyclic GMP. 0.1-ml aliquots of these suspensions were then added to 0.05 ml of a cell suspension medium containing the same Ca-EGTA buffers, in the absence of other additions (○) or in the presence of OAG (◇) or thrombin (◆). The final concentrations of thrombin and OAG were 0.6 U ml^{-1} and 7.5 μg ml^{-1}, respectively. The cell suspensions were incubated for 5 min at 22 °C before being centrifuged, and the supernatant fraction was assayed for ^{14}C content as described for Fig. 1. Data points refer to the mean of four determinations, with the error bars showing the s.e.m. The difference in the relative extents of the responses to thrombin and OAG as compared with their similarity in Fig. 1 results from the use of different OAG concentrations in these two experiments.

Studies similar to those shown in Fig. 2 have been performed using OAG instead of thrombin. Addition of cyclic AMP (20 μM) reduces the extent to which OAG shifts the dose–response curve for activation by Ca^{2+} to the left. However, the effect of cyclic AMP on the Ca^{2+}-dependent response to OAG or TPA occurs at a much higher concentration ($IC_{50} > 10$ μM) than that which inhibits the response to thrombin ($IC_{50} = 0.3$ μM) (data not shown but see Fig. 4). The effect of these cyclic nucleotides on the secretory response to thrombin or OAG has also been examined in conditions which partially simulate conditions in the intact cell. At a Ca^{2+} concentration of 0.17 μM, which approaches that typical of unstimulated intact platelets[5], addition of thrombin or OAG causes little increase in the secretory response. This small response is not obviously inhibited by 3 μM cyclic AMP. The response to thrombin, but not to OAG, is enhanced by addition of 5 μM cyclic GMP (Fig. 4*a*), in accord with the ability of cyclic GMP to enhance only the increase in the Ca^{2+} sensitivity of thrombin-induced secretion (Fig. 2 and data not shown). At a higher Ca^{2+} concentration (0.4 μM) which is still below the threshold for induction of shape change by ionomycin[5], a significant secretory response results from addition of either thrombin or OAG (Fig. 4*b*). At this higher Ca^{2+} concentration the response to thrombin is further enhanced in the presence of 5 μM cyclic GMP but is clearly inhibited in the presence of 3 μM cyclic AMP. The response to OAG is, in contrast, unaffected by the presence of cyclic GMP and is only slightly reduced by cyclic AMP (Fig. 4*b*).

These data therefore suggest that cyclic nucleotide control is primarily, although not exclusively, exerted before the formation of 1,2-diacylglycerol. Our data provide strong support for inhibition of phospholipase C by cyclic AMP, which has previously been proposed on the basis of data obtained using dibutyryl cyclic AMP and intact platelets[15,16]. This inhibitory effect may be exerted directly on phospholipase C or on a factor which regulates the supply of substrate to this enzyme. However, another inhibitory site for cyclic AMP lies beyond phospholipase C, on the stimulus–response coupling pathway, but becomes important only at higher cyclic AMP concentrations. The effect of cyclic GMP is, in contrast, restricted to enhancement of the secretory response induced by thrombin at submaximal levels of Ca^{2+} (Figs 2–4), and may therefore result wholly from direct or indirect activation of phospholipase C. Such an effect is inconsistent with results obtained using intact platelets in which an increase in [cyclic GMP]$_i$ has been reported to inhibit secretion and 1,2-diacylglycerol formation[8,28,29] but accords with a study in which addition of dibutyryl cyclic GMP enhanced platelet aggregation and secretion[12]. The reason for the discrepancy with the former studies is unclear, although the *p*H and temperature used here differ substantially from the conditions in which the response of the intact cell is usually measured. However, the intact cell data may be equivocal as certain agents, for example, sodium nitroprusside, which increase [cyclic GMP]$_i$, also less effectively raise [cyclic AMP]$_i$ (ref. 28), while others, such as ascorbic acid, fail to inhibit the aggregatory response[30]. Furthermore, inhibition of responses by 8-bromo-cyclic GMP[8,28,29] is not definitive because in other systems the effects of membrane-permeant cyclic nucleotide derivatives on intact cells have not always been consistent with results obtained by direct introduction of cyclic nucleotides into the cytosol[31].

Finally, if inositol-1,4,5-trisphosphate, another product of the breakdown of triphosphoinositide by phospholipase C, causes mobilization of Ca^{2+} to the cytosol as described for the pancreatic acinar cell[32,33], control of this enzyme by cyclic nucleotides could provide coordinate regulation of Ca^{2+} mobiliza[illegible] and 1,2-diacylglycerol formation in the platelet.

We thank Professor P. F. Baker for the provision of fa[illegible]s and for helpful discussion, and Dr Y. Nishizuka for the generous gift of OAG. D.E.K. acknowledges the support of a project grant from the MRC.

Dihydropyridine BAY-K-8644 activates chromaffin cell calcium channels

Douglas and Rubin[1] suggested that "the role of acetylcholine as a transmitter at the adrenal medulla is to cause some brief change in medullary cells which allows Ca ions to penetrate them and trigger the catecholamine ejection process". The Ca^{2+}-channel blocking agents, verapamil, nifedipine and nitrendipine, have been used widely to investigate the properties of slow Ca^{2+} channels in a variety of tissues[2], including the adrenomedullary chromaffin cell[3,4]. Recently, small modifications to the nifedipine molecule produced a derivative, BAY-K-8644 (methyl-1,4-dihydro-2,6-dimethyl-3-nitro-4-(2-trifluoromethylphenyl)-pyridine-5-carboxylate), that in contrast to the Ca^{2+}-channel blocking agents, stimulated cardiac and vascular smooth muscle contractility[5]. We have tested whether this compound behaves as a Ca^{2+}-channel activator at the chromaffin cell membrane as shown by Schramm *et al.*[5] in smooth muscle cells. The experiments described here strongly suggest that it does so.

Cat adrenal glands were isolated and prepared for retrograde perfusion with Krebs-bicarbonate solution at room temperature[6]. After 1 h initial perfusion with oxygenated Krebs-bicarbonate solution, spontaneous catecholamine outputs from cat adrenal glands amounted to 187 ± 24 ng per 10 min ($N = 75$). When the glands were subsequently stimulated for 2 min, at 30-min intervals, with isotonic solutions containing increasing concentrations of K^+, the net release of catecholamines was directly proportional to the concentration of K^+ used up to 59 mM. BAY-K-8644 at concentrations of 10^{-8}–10^{-4} M did not affect spontaneous catecholamine output; in the presence of BAY-K-8644 (1 μM), the release was 145 ± 28 ng per 10 min ($N = 42$). A drug concentration of 1 μM markedly increased catecholamine release evoked by 17.7 mM K^+; while evoked net release by K^+ was 2.93 ± 0.38 μg per 8 min ($N = 27$), in the presence of 1 μM BAY-K-8644 it was 10.1 ± 1.51 μg per 8 min ($N = 14$). Secretory responses to 59 mM K^+ were not affected by the drug. These results suggest that BAY-K-8644 is not acting on quiescent chromaffin cells and that a moderate depolarizing stimulus is required for the drug to manifest its potentiating effects on secretion. If this agent were acting on Ca^{2+} channels, the lack of potentiation of the secretory responses to higher K^+ concentrations might indicate that in these conditions, all channels are in their maximal state of activation or their most inactivated form.

Since the potentiation by BAY-K-8644 was greater at moderately depolarizing stimuli, 17.7 mM K^+ solutions were used to test the effects of varying concentrations of the drug on K^+-evoked catecholamine release. Six 2-min pulses of K^+ were given to perfused cat adrenal glands at 20-min intervals; moderate catecholamine release rates were obtained. The release was slowly decaying from the first to the sixth pulse, the amount of catecholamines found in S_6 being about 50% of that obtained in S_1 (Fig. 1*a*). In the contralateral paired gland, BAY-K-8644 started to potentiate catecholamine release at 10^{-8} M, and had already reached maximum potentiation at 10^{-7} M (Fig. 1*a*); at 10^{-6} and 10^{-5} M the potentiating effect was similar, but at 10^{-4} M the secretory response to K^+ fell abruptly, probably because at these high concentrations the drug behaves as a Ca^{2+}-channel blocking agent. The great potentiation obtained with low concentrations of BAY-K-8644 suggests a highly selective effect; since high K^+ is presumed to activate catecholamine secretion by directly depolarizing the chromaffin cell and opening voltage-sensitive Ca^{2+} channels[3,7,8], it seems feasible to assume that the target receptor for the drug is the slow Ca^{2+} channel. The fact that nitrendipine (a Ca^{2+}-channel blocking agent that potently inhibits catecholamine release evoked by nicotine or high K^+)[3] antagonizes the potentiating effect of BAY-K-8644 on K^+-evoked secretion (Fig. 1*b*), is consistent with this conjecture.

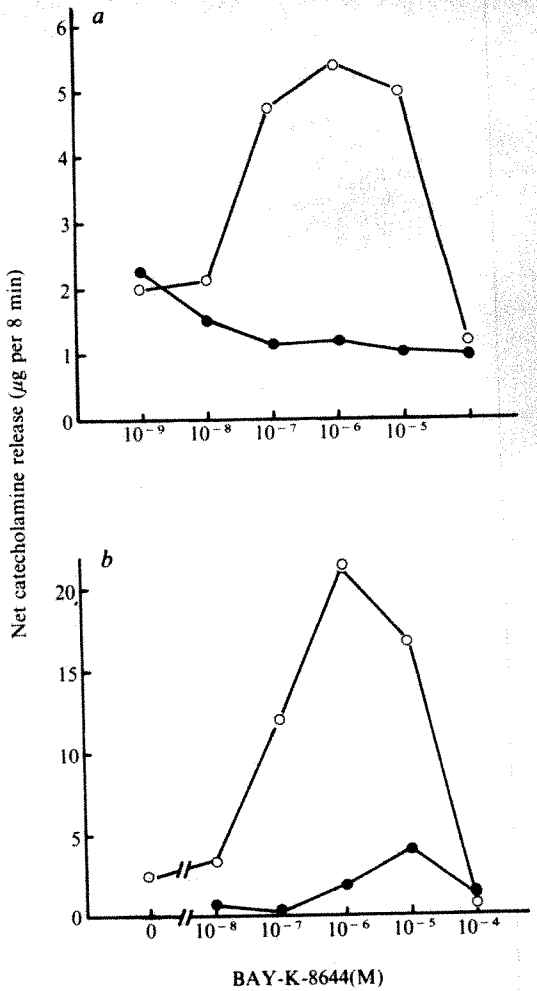

Fig. 1 Effects of increasing concentrations of BAY-K-8644 on the net release of catecholamines evoked by repeated 2-min pulses of 17.7 mM K^+ (NaCl substituted by equiosmolar amounts of KCl), given to perfused cat adrenal glands at 30-min intervals. *a*, Six pulses of K^+ were given in the absence or presence of increasing concentrations (abscissa) of BAY-K-8644. These are the results of a paired typical experiment (out of four) in which one gland was free of drug (●) and the contralateral gland was perfused with 10^{-9}–10^{-4} M BAY-K-8644 in a cumulative manner (○); each concentration of drug was added 10 min before, during the K^+ pulse and until the following concentration was introduced. *b*, A paired experiment; one gland was perfused with BAY-K-8644 at the concentrations shown on the abscissa (○); the contralateral gland was perfused in addition to this drug, with the Ca^{2+} channel antagonist nitrendipine (10^{-6} M present 10 min before the first K^+ pulse and during the rest of the experiment) (●). Total catecholamine content of perfusate samples (noradrenaline plus adrenaline) was determined without further purification on alumina[18]. Net catecholamine release during high K^+ was calculated by subtracting the basal, spontaneous release from the release obtained in the 2-min high-K^+ sample plus that obtained in three additional 2-min samples and expressed as μg per 8 min.

If BAY-K-8644 activates Ca^{2+} channels, it should favour the influx of ^{45}Ca by the chromaffin cell; this was certainly the case, as shown in the experiments of Fig. 2. The uptake of ^{45}Ca by acutely isolated chromaffin cells suspended in oxygenated Krebs-bicarbonate solution was substantially increased in the

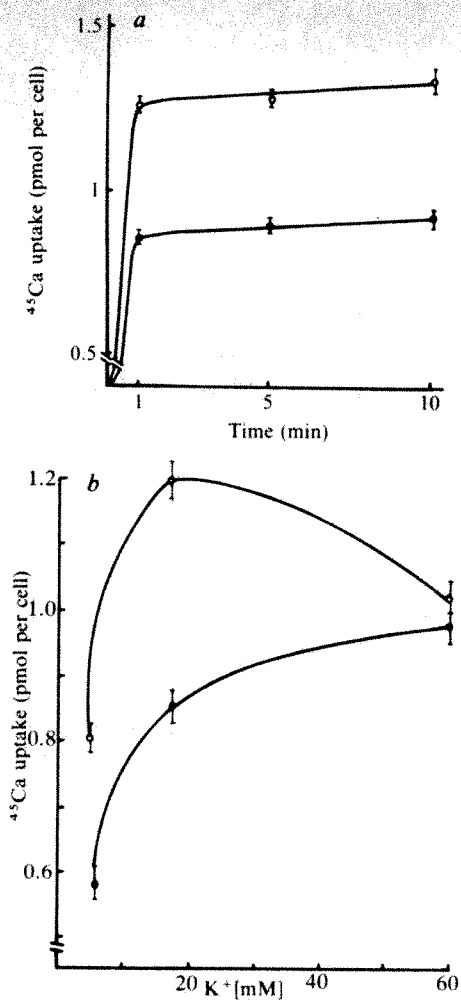

Fig. 2 BAY-K-8644 increases ^{45}Ca uptake into acutely isolated bovine adrenal chromaffin cells prepared as previously described[19] (○, BAY-K-8644; ●, control). *a*, Time course of the uptake of ^{45}Ca by chromaffin cells exposed to high K^+ (17.7 mM) solution in the absence (control) or the presence of BAY-K-8644 (1 μM). Inmediately after isolation and washing, cells were incubated in oxygenated Krebs-bicarbonate solution at 37 °C for 15 min; then aliquots of the cell suspension containing 5×10^5 cells were added to 1 ml Krebs solution with 17.7 mM K^+ (NaCl reduced equiosmotically) and 3×10^6 c.p.m. ^{45}Ca per assay (Amersham; specific activity 20.1 mCi mg^{-1}). In BAY-K-8644-treated cells, the drug (1 μM) was present 15 min before adding K^+ and ^{45}Ca. One, five or ten minutes after adding ^{45}Ca and K^+, 3 ml Krebs solution (with or without BAY-K-8644) were added and the cells centrifuged at 2,000 r.p.m. for 10 min; cells were resuspended and washed four times in the above solution. Finally, they were vigorously resuspended in 2 ml of 0.4 M perchloric acid and centrifuged at 2,000 r.p.m. for 10 min; 0.5 ml of the supernatants were added to 5 ml Instagel (Packard) and the radioactivity was counted in a LS2800 Beckman scintillation counter. ^{45}Ca taken up and retained by cells was expressed as pmol per cell (ordinate). Data are means ± s.e. of eight experiments. *b*, Effects of BAY-K-8644 on ^{45}Ca uptake by chromaffin cells suspended in solutions containing 5.9 (normal Krebs), 17.7 or 59 mM K^+. BAY-K-8644 (1 μM) was present 15 min before and during K^+ stimulation. Conditions were as above. Results are means ± s.e. of eight experiments.

presence of 17.7 mM K^+, in relation to the uptake observed in non-stimulated cells; uptake was almost complete after 1 min incubation, although it continued to rise slightly after 5 or 10 min incubation (Fig. 2*a*). When cells were suspended in the presence of BAY-K-8644 at a concentration (10^{-6} M) which maximally potentiated K^+-evoked catecholamine release (Fig. 1*a*), ^{45}Ca uptake–retention in the presence of 17.7 mM K^+ was enhanced at all incubation times studied (Fig. 2*a*). Figure 2*b* shows the uptake of ^{45}Ca in the presence of 17.7 or 59 mM K^+; BAY-K-8644 increased ^{45}Ca influx significantly ($P < 0.001$, $N = 8$) at

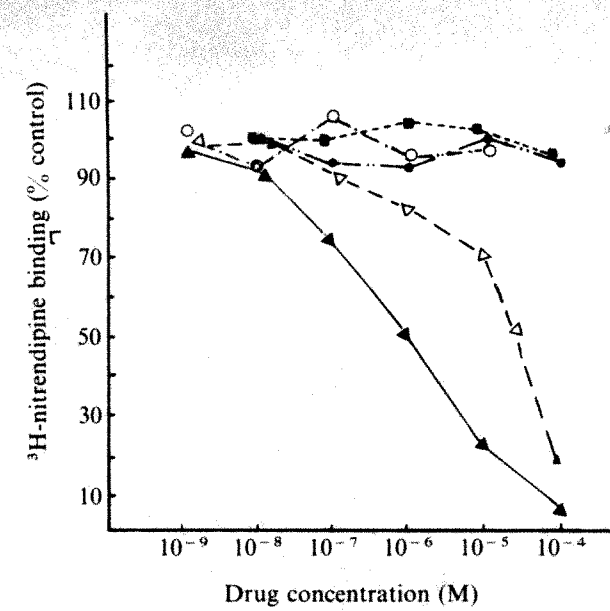

Fig. 3 Specific binding of ^{3}H-nitrendipine to bovine adrenomedullary membrane fragments and its displacement by BAY-K-8644. A crude microsomal fraction isolated from bovine adrenal medulla homogenates (0.3 M sucrose containing 10 mM Tris buffer, *p*H 7.4) was used as the source of membranes. The reaction mixture consisted of 300 μg membrane protein, 50 mM Tris buffer *p*H 7.4, 1 nM ^{3}H-nitrendipine and increasing concentrations of displacing agent (abscissa). Incubation was at 37 °C under a sodium lamp for 30 min. The ordinate shows ^{3}H-nitrendipine specifically bound to membranes as % of maximal binding in the absence of displacing agent. IC_{50} values for nitrendipine and BAY-K-8644 were, respectively, 1 and 50 nM. Data are means ± s.e. of three to six experiments. ○, Imipramine; ●, cocaine; ■, nicotine; △, BAY-K-8644; ▲, nitrendipine.

the lower K^+ concentration but not when 59 mM K^+ was used, suggesting once more that at higher K^+ concentrations, Ca^{2+} channels might be fully activated and that ^{45}Ca entry through them cannot be further increased. Note that BAY-K-8644 also slightly but significantly enhanced the ^{45}Ca taken up by quiescent cells ($P < 0.01$, $N = 8$); this finding contrasts with the lack of effect of the drug on spontaneous catecholamine release or rabbit aorta contractility[5]. Even so, these experiments support the suggestion that this agent is promoting Ca^{2+} uptake thr specific voltage-sensitive Ca^{2+} channels.

^{3}H-nitrendipine has been used as a specific radioliga characterize the dihydropyridine receptor probably asso with the Ca^{2+} channel in various tissues[9] including the a medulla[10]. Since nitrendipine antagonized the potentiating effects of BAY-K-8644 on catecholamine release evoked by high K^+, the possible modification of ^{3}H-nitrendipine binding to membranes could help to define further its presumed binding site on the chromaffin cell membrane and potentiation of K^+-evoked catecholamine release. Measurements of ^{3}H-nitrendipine-specific binding to membrane fragments from bovine adrenal medulla demonstrate a saturable binding with an apparent K_D of 1.18 ± 0.32 nM and a B_{max} of 325.4 ± 136 fmol per mg protein ($N = 4$). These values are compatible with the presence in the chromaffin cell membrane of a high-affinity binding site probably associated with the voltage-dependent Ca^{2+} channel. The specificity of the radioligand for the Ca^{2+} channel is further corroborated by the fact that agents which bind to the acetylcholine site (nicotine) or to the ionophoric site (imipramine, cocaine)[3] of the nicotinic cholinoceptor did not affect ^{3}H-nitrendipine binding (Fig. 3). In contrast, BAY-K-8644 fully displaced ^{3}H-nitrendipine bound to membranes, suggesting once more that this drug is acting on the voltage-sensitive Ca^{2+} channel.

Studies involving measurements of catecholamine release

evoked by depolarizing agents[3,11–13], and monitoring of ^{45}Ca transmembrane fluxes[14–16] or electrical recordings using patch-clamp techniques[17] have indicated the presence in the chromaffin cell membrane of slow Ca^{2+} channels which are sensitive to voltage changes. The potency of nitrendipine in inhibiting[3] and that of BAY-K-8644 in enhancing K^+-evoked catecholamine release suggests that the chromaffin cell membrane might contain a 'dihydropyridine' receptor closely related to this voltage-sensitive slow Ca^{2+} channel; if so, it is likely that an endogenous modulator for such a receptor might be manufactured by the cell to control the activation and inactivation of Ca^{2+} channels either from the cytosol or from the cell exterior after its exocytotic release, as suggested for smooth muscle cells[5]. In any case, the dihydropyridine BAY-K-8644 might be the first compound available to manipulate pharmacologically the rates of activation or inactivation of Ca^{2+} channels; if so, it will prove a useful tool for studying the properties of such channels as well as their functional dynamics during the secretory cycle for catecholamines and other neurotransmitters and hormones.

We thank Professor F. Hoffmeister (Bayer AG) for the generous supply of nitrendipine and BAY-K-8644. This work was supported by grants from CAICYT (Ministerio de Educación y Ciencia) and FISS (Ministerio de Sanidad y Consumo), Spain. We thank Mrs Julia Romeo for typing the manuscript.

A haemoglobin switching activity modulates hereditary persistence of fetal haemoglobin

Thalia Papayannopoulou*, Basil Tatsis†, Sumiko Kurachi*, Betty Nakamoto* & George Stamatoyannopoulos*

During human development there is a switch from fetal to adult haemoglobin formation, reflecting the differential expression of fetal ($^G\gamma$ and $^A\gamma$) and adult (β and δ) globin genes. Mutations that inhibit this switch produce variants of the syndrome of hereditary persistence of fetal haemoglobin (HPFH). Adult heterozygotes for these mutants produce 15–30% fetal haemoglobin (HbF) in their red cells[1]. The general assumption is that the mutations result in a permanent switching on of γ-globin genes. Here, however, we show that fetal globin expression can be turned off in cultures of HPFH cells by an uncharacterized factor in fetal sheep serum. This is the first demonstration that mutations affecting the developmental expression of globin genes can be modulated by exogenous factors. The findings raise the possibility that the phenotype of HPFH is not simply the direct result of mutations in or around globin genes but the consequence of the mutations on the interaction of globin genes with *trans*-acting regulatory factors.

The studies described here followed the observation that an activity (named haemoglobin switching activity[2–4]) present in sera from sheep fetuses has profound effects on HbF expression in cultures of human erythroid cells. This activity (the nature of which remains unknown) turns off HbF synthesis in cultures of erythroid progenitors from normal adults, from persons with activated HbF synthesis *in vivo*, and from patients with sickle cell anaemia or a β-thalassaemia syndrome[2–4]. The activity induces switching of HbF to HbA synthesis in neonatal erythroid progenitor cultures, but fails to induce HbF to HbA switching in cultures of fetal burst-forming units (BFU-E)[2–4]. *In vitro* studies suggest that haemoglobin switching occurs through a direct interaction with early as well as late erythroid progenitors[3].

The availability of culture conditions that can modify HbF expression has enabled us to study HPFH mutations. HPFH mutations with *cis* $^G\gamma$ and $^A\gamma$ but not β and δ ($^G\gamma^A\gamma$ HPFH) globin expression or *cis* $^G\gamma$ ($^G\gamma$ HPFH) or $^A\gamma$ ($^A\gamma$ HPFH) chain synthesis are known[1]. Previous structural analyses have revealed various deletions in the β-globin genomic regions of $^G\gamma^A\gamma$ HPFH mutants but no globin gene abnormalities in the $^G\gamma$ or $^A\gamma$ HPFH mutants[5–15]. How these mutations continue to express HbF in the adult and whether the structural anomalies of the $^G\gamma^A\gamma$ HPFH mutations affect the normal mechanism that controls haemoglobin switching, remain unknown.

In the present study, erythroid progenitors (BFU-E) were cultured in the conditions described in Fig. 1 legend. Cells were grown in semisolid media and mature erythroid clones collected after 15–17 days in culture, incubated with ^3H-leucine and used to measure the incorporation of radioactivity into the globin chains as described previously[16,17]. Media in control cultures contained fetal calf serum (FCS). In the experimental cultures, FCS was substituted by a preparation of fetal sheep serum (FSS) which potently induced HbF to HbA switching in cultures of neonatal BFU-E and BFU-E from persons with an acquired HbF elevation.

As shown in Fig. 1, cultures of cells from two $^G\gamma^A\gamma$ HPFH heterozygotes (having a mutation that deletes part of the $^A\gamma$ to δ flanking region, the δ and β genes and several kilobases 3′ of the β gene) produced 25–40% HbF in the control FCS cultures. In FSS cultures, however, HbF synthesis ranged from barely detectable to a maximum of 2%. Cells from two other $^G\gamma^A\gamma$ HPFH carriers, in whom the molecular lesion has not been defined, showed a similar degree of abrogation of HbF synthesis in FSS cultures. To test the response of non-deletion HPFH variants, we cultured erythroid cells from a heterozygote for the Greek $^A\gamma$ HPFH and a heterozygote for the African $^G\gamma$ HPFH. These cells produced 20–35% HbF in FCS cultures, but barely measurable amounts in FSS cultures (Fig. 1).

Several experiments were done to determine the reason for the inhibition of HPFH expression in FSS cultures. It is known that γ and β globins are produced asynchronously during erythroblast maturation, γ globin and γ mRNA accumulating in immature erythroblasts, with β-globin expression increasing in mature erythroblasts[18,19]. To test whether FSS decreased HbF through this maturational mechanism, deletion HPFH BFU-E were cultured and immature clones (composed of proerythroblasts and basophilic erythroblasts) or mature clones (composed of polychromatophilic and orthochromatic erythroblasts) were collected separately and used to assess globin biosynthesis. We found that the immature HPFH erythroblasts had the low γ-globin synthesis characteristic of FSS cultures, a result eliminating the possibility of maturational modulation and suggesting

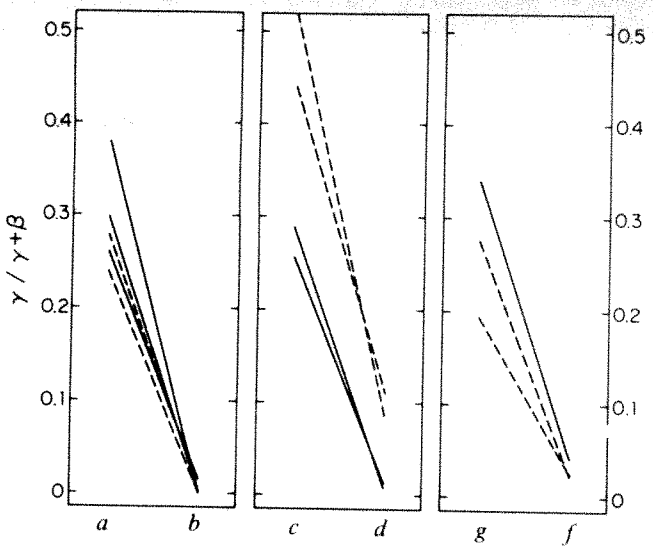

Fig. 1 Globin chain biosynthesis (expressed as $\gamma/\gamma+\beta$ ratio) in cultures of erythroid cells from humans heterozygous for hereditary persistence of fetal haemoglobin. *a*, Cultures performed in FCS. *b*, Cultures performed with FSS containing haemoglobin switching activity. Each line represents the results of a separate experiment. Left panel: results with cells of two $^{G}\gamma^{A}\gamma$ HPFH heterozygotes who, by globin gene restriction endonuclease mapping, were found to carry the Ghana type deletion HPFH mutation[11,15]. Middle panel: results from cultures of two $^{G}\gamma^{A}\gamma$ HPFH heterozygotes whose mutation has not been molecularly characterized. Right panel: findings in two non-deletion mutations, $^{G}\gamma$ HPFH (—) and Greek $^{A}\gamma$ HPFH (---). Note in all panels the striking reduction of γ-globin synthesis in *b*. In addition to the striking differences in $\gamma/\gamma+\beta$ ratios, the α/non-α ratios differed between FCS and FSS cultures (being 10–20% higher in the latter). This is expected, as turning off the γ-chain, synthesis in the mutant HPFH chromosome will result in α/non-α chain imbalance.
Methods: Peripheral blood was used as a source of erythroid progenitors. After Hypaque–Ficoll centrifugation interphase cells were collected, washed and adhered to plastic surfaces to remove the majority of adherent cells. Non-adherent cells were inoculated at appropriate concentrations ($1–3\times10^{5}$ ml^{-1}) in methylcellulose in the presence of erythropoietin, T-cell-derived conditioned medium and either FCS or a FSS preparation known to contain Hb switching activity. In these conditions erythroid progenitors (burst forming units, BFU-E) produce large, multi-lobed erythroid colonies (erythroid bursts) that mature in culture during days 13–20. Mature erythroid bursts were lifted from the plates, pooled according to experimental category and used to measure globin chain synthesis.

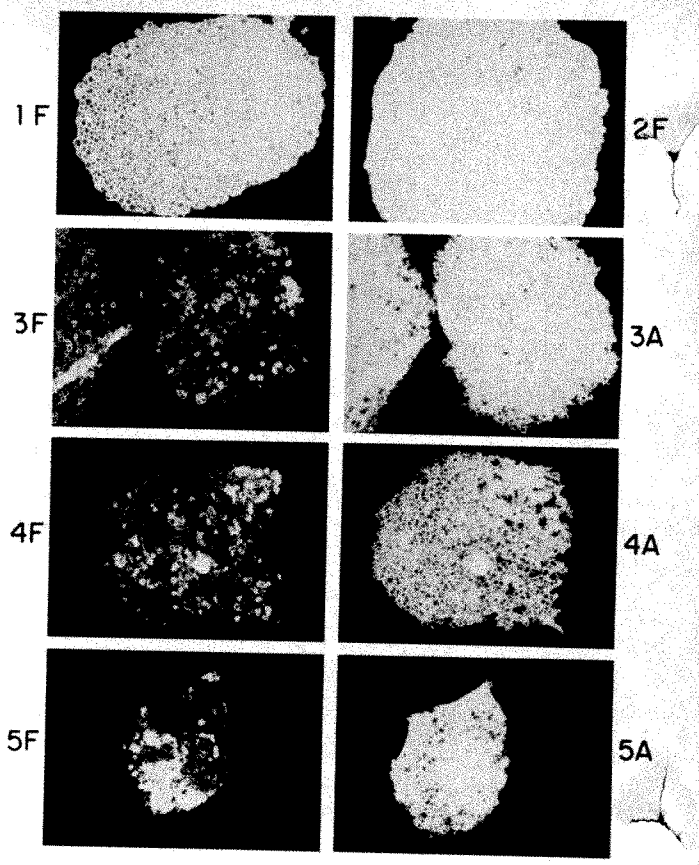

Fig. 2 Immunofluorescent labelling of HPFH clones. Mature clones were lifted from the cultures, fixed and labelled with an anti-γ chain monoclonal antibody and rabbit anti-mouse F(ab)$_2$-fluorescein isothiocyanate (FITC) and counter-labelled with an anti-β globin chain monoclonal antibody conjugated to rhodamine. This double-labelling approach allows detection of both γ and β globins in each cell of a clone. 1F and 2F show two FCS-grown clones labelled with the anti-γ globin–FITC. Note the strong labelling of all the cells. 3, 4 and 5 are FSS-grown clones labelled with anti-γ FITC (3F, 4F, 5F) and anti-β rhodamine (3A, 4A, 5A). Note that in 3F, 4F and 5F the majority of cells either fail to be labelled by the anti-γ-chain antibody or are labelled very faintly, showing the reduced total accumulation of HbF in the cells of FSS-grown clones.

that the FSS-grown immature HPFH erythroblasts already have been programmed to produce low amounts of HbF. To test whether our findings reflected an absolute reduction of γ-globin chain production, we performed experiments using fluorescent anti-globin chain monoclonal antibodies. A double-labelling procedure (described in Fig. 2 legend) was used and over 50 clones (per experiment) were analysed for γ- and β-globin expression. Clones grown in FCS displayed the pancellular expression of HbF characteristic of HPFH mutations (Fig. 2) whereas in most FSS-grown HPFH clones, γ globin was barely detectable. In other experiments, some cells from FSS-grown clones expressed HbF (Fig. 2). These results showed that culture in FSS results in a marked reduction of γ-chain expression in the HPFH erythroblasts.

To test directly whether HbF was turned off through an interaction between HPFH cells and the switching activity in FSS cultures, experiments were performed using split clones. Deletion HPFH BFU-E were cultured in either FCS or FSS. When the clones had reached a size of about 50 cells (five to six progenitor cell divisions), each clone was divided into two almost equal parts, one part being transferred to a plate containing FCS, the other part to a plate containig FSS. The clones were left to grow and mature (five to six cell divisions) and then used for globin analysis. As shown in Table 1, there are striking differences in HbF production between the parts of a clone transferred to FSS or to FCS, showing directly that the progeny of the same HPFH progenitor can produce high or low HbF depending on the environment. Of special significance are the low HbF levels observed in the FSS to FCS transfers (Table 1); they show that the expression of the HPFH mutation can be altered even when the cells forming a clone are exposed to the inductive environment only during the initial stages of their *in vitro* differentiation.

The present findings in HPFH cultures are identical to findings in normal and haemoglobinopathic cell cultures reported by us previously[2–4]. The fact that the HPFH cells return to the normal pattern for adult cells (that is, turning off HbF expression) when cultured in FSS suggests that the HPFH mutations can be modulated by exogenous factors. Previously, the phenotypic consequences of HPFH mutations have been interpreted to mean that in the deletion mutations, a *cis*-acting regulatory element which usually turns off the γ genes is deleted, while the non-deletion HPFH are mutations of *cis*-acting elements that regulate the individual $^{G}\gamma$ or $^{A}\gamma$ genes. The results presented here are compatible with an alternative postulate: in HPFH, the response of the mutant globin genomic regions to normal

Table 1 Synthesis of fetal haemoglobin in divided HPFH clones

Clone no.	Initial growth in	$\gamma/\gamma+\beta$ in part of clone grown in FCS	FSS
1	FCS	0.26	0.01
2	FCS	0.35	0.03
3	FCS	0.22	0.01
4	FCS	0.33	0.02
5	FCS	0.24	0.03
6	FCS	0.59	0.02
7	FCS	0.33	0.06
8	FSS	0.18	0.02
9	FSS	0.13	0.01
10	FSS	0.12	0.02
11	FSS	0.07	0.01
12	FSS	0.15	0.03
13	FSS	0.19	0.02
14	FSS	0.15	0.01

Clones were grown in FCS or FSS. At the 30–50-cell stage the clone was divided into two parts by *in situ* micromanipulation. Using an ultrathin pipette, one part of the clone was lifted and implanted in a cell-free methylcellulose plate containing FCS; the other part of the clone was lifted and implanted in a cell-free methylcellulose plate containing FSS. The transferred parts of the clones were left to grow and mature. At maturation the two parts were of similar sizes (as shown by surface counting). The mature clones were plucked out of the plates, and each part was incubated with ^{3}H-leucine separately and used for globin chain isoelectric focusing to measure the $\gamma/\gamma+\beta$ globin chain synthesis ratio.

trans-acting regulatory elements that control haemoglobin switching may be altered, so that higher levels of *trans*-acting regulatory elements are required to turn off the expression of HbF in the mutant adult cells. The differences in the degree of inhibition of HbF noted in the split clone transfers (Table 1) and in the studies of single clones by immunofluorescence support this postulate. The hypothesis can also explain the paradox that HbF can be turned off *in vitro* in mutants that express this haemoglobin *in vivo* in conditions of normal erythropoiesis.

Previous work has shown that adult erythroid progenitors have an inherent potential to form progeny which express fetal haemoglobin[20]. This HbF potential is presumably lost during downstream differentiation through interactions between progenitors and the inductive environment of adult haematopioesis[2,3,20]. In HPFH mutations, the structural anomalies in the globin genomic region are expected to augment the HbF potential of erythroid progenitors. In the conditions of haematopoietic differentiation that prevail in the marrow of HPFH heterozygotes, the normal level of the inductive environment is not enough to modulate the augmented HbF potential of HPFH progenitors, and terminal cells expressing HbF are formed. In FSS cultures, haemoglobin switching activity is present in excess throughout erythroid cell development, allowing a degree of cell–environment interaction that can turn off the augmented HbF potential of HPFH progenitors; as a result, erythroblasts lacking HbF are produced.

These studies were supported by NIH grants HL 20899 and AM 20233.

Contribution of human $V_{\kappa II}$ germ-line genes to light-chain diversity

H.-G. Klobeck*, A. Solomon† & H. G. Zachau*

* Institut für Physiologische Chemie, Physikalische Biochemie und Zellbiologie der Universität München, FRG
† Department of Medicine, University of Tennessee Memorial Research Center and Hospital, Knoxville, Tennessee 37920, USA

The genetic basis of the antibody repertoire—estimated to exceed 10^6 different immunoglobulin molecules—is a major unanswered problem[1,2]. The number of germ-line V_κ genes in the mouse genome is probably several hundred[3,4] while the corresponding number for three out of four human V_κ subgroups ($V_{\kappa I}$, $V_{\kappa III}$ and $V_{\kappa IV}$) is probably altogether only 15–20 (ref. 5). The κII proteins differ significantly in sequence from the other κ-chain proteins[6]. To determine the contribution of $V_{\kappa II}$ genes to κ-chain diversity, we searched for a human lymphoid cell line which produces a κII chain and report here for the first time the sequence of a $V_{\kappa II}$ gene. According to blot hybridizations with this V_κ gene as a probe, subgroup II contributes about half as many genes to the V_κ gene repertoire as are detected by a $V_{\kappa I}$ probe. Therefore the repertoire is rather small which implies that somatic mutations[7–9] or other mechanisms must play an important role in the generation of light-chain diversity in humans.

Subgroups I–III (refs 10, 11), and IV (ref. 12) were defined on the basis of the amino acid sequences of κ-type Bence–Jones and myeloma proteins. All human κ chains now known fit into this classification[6]. Recently, it has become clear that both a number of germ-line V_κ genes and somatic processes, including somatic point mutations, contribute to the sequence variation among light chains[1,2]. Recent advances in molecular cloning have made it possible to estimate the relative contribution of germ-line V_κ genes to the light-chain diversity. $V_{\kappa I}$ and $V_{\kappa III}$ probes hybridized not only with each other but also detected, in blot experiments with digests of total human DNA, essentially the same bands corresponding probably to the same 15–20 V_κ genes[5]. Since subgroup I and III proteins are more closely related to subgroup IV proteins than to one another, it was suggested[5] that these 15–20 genes may also contain the $V_{\kappa IV}$ genes.

The development of subgroup specific antisera[13] made it possible to assign κ chains to the subgroups without determining the amino acid sequences. Using such antisera in immunodiffusion assays with supernatants from various cell lines we found that the κ chain excreted by the human lymphoblastoid cell line GM 607 belongs to subgroup II. The cell line GM 607 which had been used in a number of studies (see, for example, ref. 14) contains one rearranged and one germ-line C_κ gene. The rearranged V_κ–C_κ region was cloned (Fig. 1) and the V_κ gene region sequenced (Fig. 2). The amino acid sequence which was obtained from the DNA sequence confirms the serological assignment of the GM 607 κ chain to subgroup II. Codons 97–108 are derived from the gene segment J1. The assignment of the sequence to subgroup II is unequivocal since all subgroup specific amino acids were found in the characteristic positions[6] and there is a 98% homology to the published sequence of the

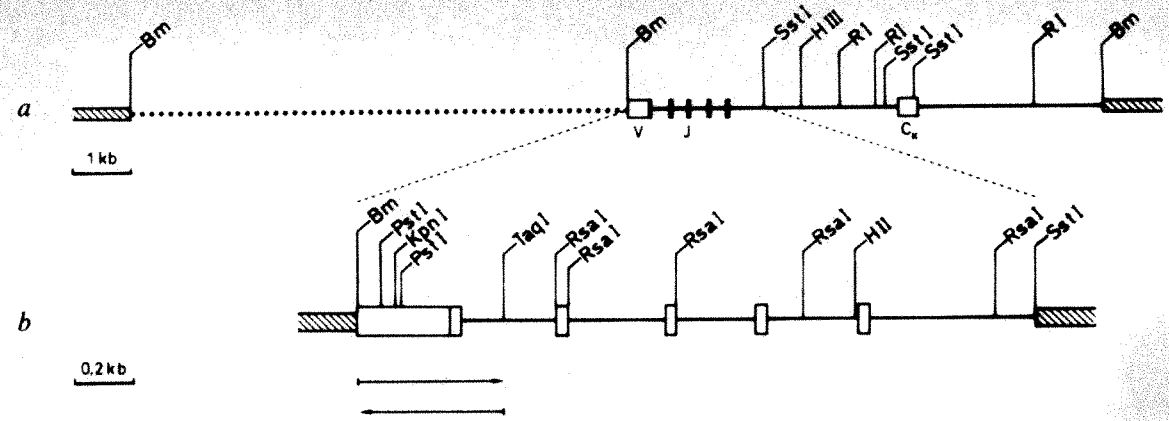

Fig. 1 Restriction map and sequencing strategy of a V_κ gene cloned from DNA of the lymphoblastoid cell line GM 607. The cell line which had been derived from a clinically unaffected person was obtained from the Human Genetic Mutant Cell Repository (Camden, New Jersey). A *Bam*HI digest of GM 607 DNA was electrophoretically separated and the 8-kb region cloned in Charon 30 (ref. 20). This is the region which hybridized with a cloned 2.6-kb *Eco*RI fragment from the human C_κ region[21]. The C_κ clone was derived from a 10.6-kb *Bam*HI clone which in turn had been isolated from human placenta DNA using a mouse J_κ region clone (1.56-kb *Hin*dIII–*Hin*dII; ref. 22). From the GM 607 clone (*a*) which contains an unrelated DNA fragment (.....) in addition to the κ gene, the subclone (*b*) was prepared in a pBR322 derivative which contains a *Sst*I site instead of the *Hin*dIII site. For sequencing, the *Bam*HI–*Taq*I fragment was cloned in M13mp8 and 9 (ref. 23). Bm, *Bam*HI; HII, *Hin*dII; HIII, *Hin*dIII; RI, *Eco*RI.

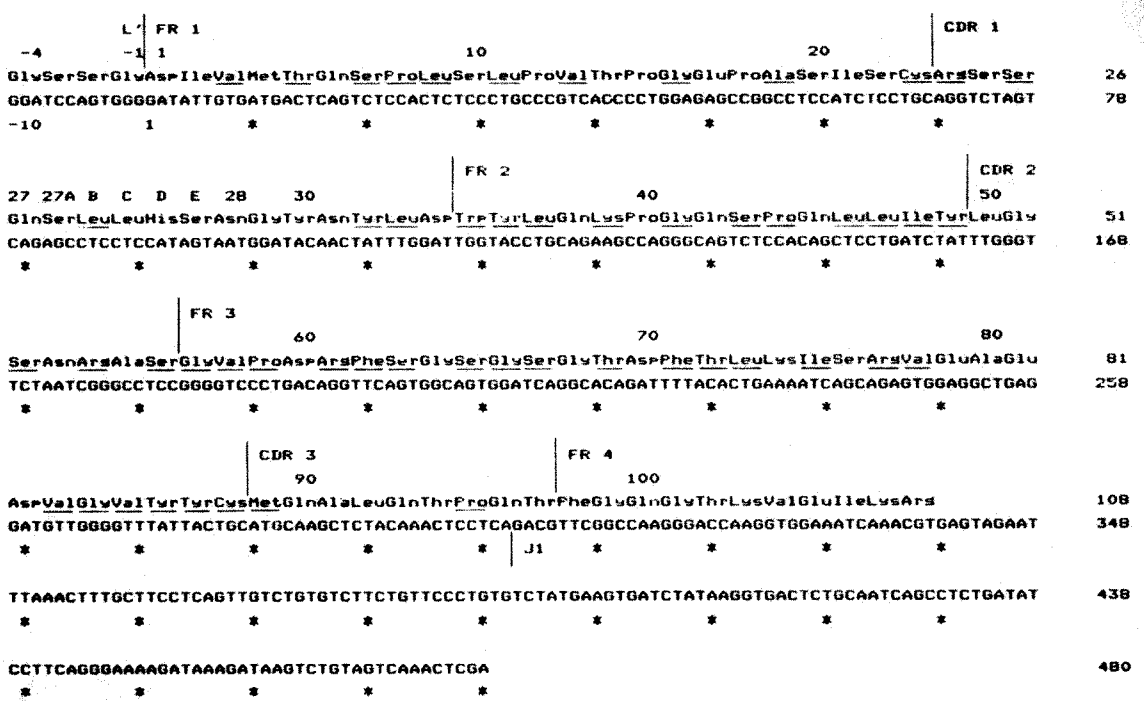

Fig. 2 Sequence of the V_κ–J_κ gene region of the rearranged allele of GM 607. The M13mp8 and mp9 subclones (Fig. 1) were sequenced by the chain terminator method[24] using 1-m long gels (ref. 25 and H. R. Jaenichen *et al.*, manuscript in preparation). Numbering of codons/amino acids is according to Kabat *et al.*[6]. $V_{\kappa II}$ specific amino acids are underlined. The J1 and intron sequence is identical to the sequence of Hieter *et al.*[21] except for a GTG instead of a GTTG and a C instead of a T (positions 401–403 and 436, respectively, in our numbering). Regions: L', leader; FR, framework; CDR, complementarity determining.

Bence–Jones protein TEW[15]; there is 93% homology, if gaps are counted as one mismatch each and amide differences are included. Since our clone does not extend as far in the 5′ direction as the region in which intron and leader sequences would be located, the assignment of codons −1 to −4 to amino acids of the leader remains tentative.

The sequence of the V_κ gene of GM 607 shares 64% homology with the published sequence of the $V_{\kappa I}$ gene HK 102 (ref. 16) which has been confirmed and extended in our laboratory (H. R. Jaenichen *et al.*, manuscript in preparation). In this sequence comparison the 15 base pairs (bp) from position 82 to 96 which are not present in the $V_{\kappa I}$ gene are counted as one mismatch. The homologies between the complementarity determining regions of the $V_{\kappa I}$ and $V_{\kappa II}$ genes were found to be low: CDR1, 55%; CDR2, 33%; CDR3, 29%. Although the framework regions of the two genes show fairly high homologies (FR1, 62%; FR2, 80%; FR3, 76%) the degree of cross-hybridization was very low. In dot blot[17] experiments (Fig. 3) 3% of cross-hybridization were found under stringent and 4–5% under non-stringent conditions. In Southern blot hybridizations[18] cross-hybridization between the subgroup I and II genes was barely detectable.

To estimate the approximate number of germ-line $V_{\kappa II}$ genes restriction nuclease digests of total human DNA were hybridized

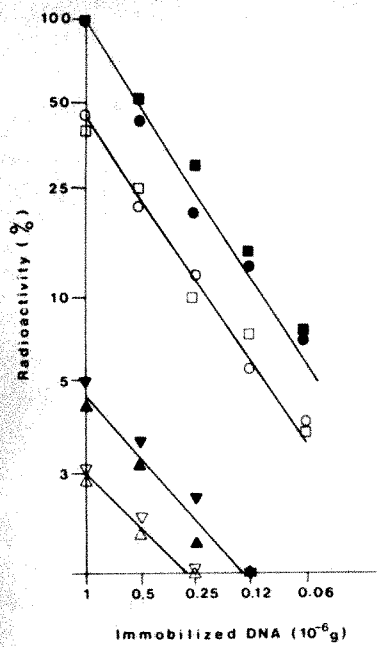

Fig. 3 Cross-hybridization between V_κ genes of subgroups I and II. The DNAs used were derived from the GM 607 subclone in M13mp9 (Fig. 1) ($V_{\kappa II}$) and from a $V_{\kappa I}$ clone in M13 phage. The inserts comprise 492 and 550 bp, respectively, the latter one being identical to the *Pst*I fragment of HK 102 (ref. 16; H. R. Jaenichen *et al.*, manuscript in preparation). The inserts were self-ligated to sizes of at least 5 kb. Approximately 0.06 to 1 μg DNA each of the DNAs were applied to nitrocellulose paper and immobilized[17]. The same DNAs were nick-translated to about equal specific radioactivities with [α-^{32}P]dATP and [α-^{32}P]dCTP[26]. Self- and cross-hybridizations were carried out in 6×SSC at 68 °C; washing was with 6×SSC or down to 0.1×SSC (non-stringent and stringent, respectively). Individual dots were cut out (1 cm^2 each), counted, and the values plotted (after subtraction of blanks); non-stringent self-hybridizations (~4,000 c.p.m.) were taken as 100%. Self-hybridizations with $V_{\kappa I}$ DNA (○, ●) and $V_{\kappa II}$ DNA (□, ■), cross-hybridizations with $V_{\kappa I}$ (△, ▲) and $V_{\kappa II}$ (▽, ▼) DNAs as probes; open and closed symbols represent stringent and non-stringent conditions.

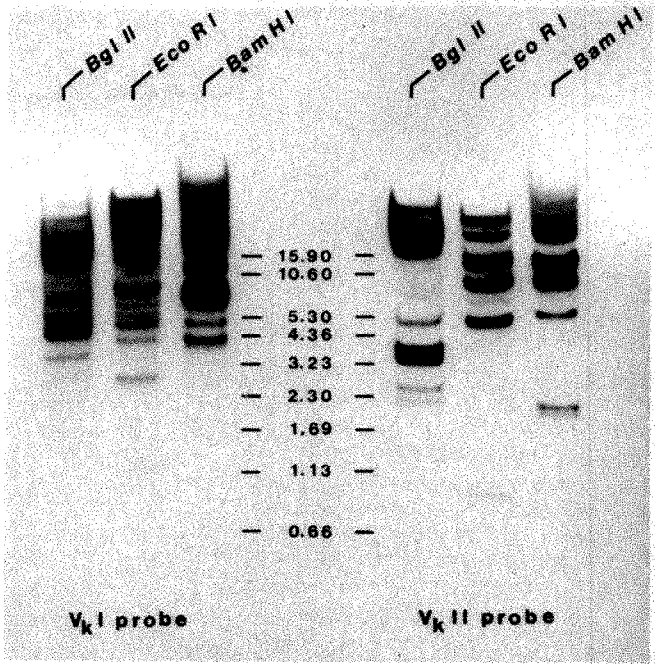

Fig. 4 Hybridization of restriction nuclease digests of total human DNA with $V_{\kappa I}$ and $V_{\kappa II}$ probes. 15 μg each of *Bam*HI, *Eco*RI and *Bgl*II digests of human placenta DNA were separated electrophoretically on 6 mm thick 1% agarose gels in a buffer (similar to ref. 27), 40 mM Tris, 20 mM sodium acetate, 1 mM EDTA, *p*H 7.4. After blotting[18] hybridization with the nick-translated probes (Fig. 3) was in 3×SSC at 68 °C and washing in 2×SSC. Autoradiography was without intensifying screens.

under various conditions with the $V_{\kappa II}$ and, for comparison, the $V_{\kappa I}$ probes (Fig. 4). With the $V_{\kappa I}$ probe we obtained band rns very similar to those of Bentley and Rabbitts[5] who ɔreted them to represent 15–20 V_κ genes. Such an interpretation is possible since the authors found only little polymorphism of restriction sites in the V_κ locus; they also took into account, as far as possible, the different intensities of the bands in the blot hybridization experiments. On the same basis we estimate that the $V_{\kappa II}$ subgroup contains about half as many genes as are detected with the $V_{\kappa I}$ probe. The strong bands of the $V_{\kappa II}$ patterns cannot represent $V_{\kappa I}$ genes because cross-hybridization between the two DNA probes is negligible.

Any figure for the number of different genes in the human V_κ locus which is based on the counting of bands in an electrophoretic separation can be taken only as an estimate. The sequence divergence within the subgroups could be rather high so that a subgroup-specific probe would detect extreme variants only as weak bands. The degree of cross-hybridization between the subgroups, on the other hand, is difficult to predict on the basis of amino acid or even nucleic acid sequences; this may be a source of both possible over- and underestimates of gene numbers. The presence of very homologous genes probably arising from recent gene duplication(s) in the V_κ locus, means that the actual number of V_κ genes detected by a subgroup I probe may be somewhat higher[19] than originally proposed[5]. When several hybridization probes are available for each of the four subgroups it will be possible to make more exact estimates. The number of V_κ genes will be known definitely only after the whole V_κ locus has been cloned. Since only sequencing can distinguish between potentially functional genes and pseudogenes, the exact determination of the functional V_κ gene repertoire is a long-term project. Present estimates, however, clearly indicate that in humans the V_κ gene repertoire is relatively small and that other mechanisms, for example, somatic mutation, must contribute significantly to the generation of the V_κ-sequence diversity.

After submission of the present report, a paper was published[28] describing the sequence and hybridization properties of a $V_{\kappa III}$ cDNA. The results are interpreted to be in agreement with Bentley and Rabbitts[5] and 50 or less germ-line V_κ genes are proposed.

We thank G. Combriato and D. Weiss for assistance, R. Linke for help in the initial serological experiments, H. R. Jaenichen for the $V_{\kappa I}$ probe and for help with sequencing, and P. S. Neumaier for help in the preparation of Fig. 2. The work was supported by Bundesministerium für Forschung und Technologie, Fonds der Chemischen Industrie, and by NCI grant CA 10056.

Isolation of a cDNA clone coding for an SB β-chain

Kenth Gustafsson, Eva Emmoth, Eva Widmark, Jan Böhme, Per A. Peterson & Lars Rask*

Department of Cell Research, The Wallenberg Laboratory, University of Uppsala and *Swedish University for Agricultural Sciences, Box 562, S-751 22 Uppsala, Sweden

Class II antigens of the major histocompatibility complex (MHC) consist of a family of closely related cell surface-expressed glycoproteins. These antigens, which are genetically polymorphic, control important aspects of the immune response[1]. At least three types of human class II antigens, namely, DR, DC and SB (refs 2–4), have been identified. All class II antigens are heterodimers composed of one α- and one β-chain. The genes for both types of subunits are encompassed within the MHC[5,6]. The general features of the DC and DR antigens have recently been elucidated[7–15]. Much less is known, however, about the SB molecules[16]. Here we describe the isolation of a cDNA clone as well as a genomic clone encoding a β-chain whose amino acid sequence is compatible with the partial amino-terminal sequence of SB β-chains[16].

Recent studies have shown that part of the 3′-untranslated regions of DR and DC cDNA clones can be used as locus-specific probes in hybridization experiments[17]. This information prompted us to isolate non-DR, non-DC locus-derived cDNA clones from a previously described library[18]. Colony hybridizations were carried out separately using probes corresponding to the translated and the 3′-untranslated portions of DR and DC β cDNA clones, respectively[12,19]. One cDNA clone, pII-β-7, hybridized to the probes corresponding to the translated portions but did not hybridize to the 3′-untranslated probes. Therefore, pII-β-7 was characterized by restriction mapping and nucleotide sequence analysis. Figure 1 summarizes the results and displays the amino acid sequence predicted from the nucleotide sequence; the data demonstrate that pII-β-7 is truncated in the 5′ region as only three of the four cysteine codons, characteristic for all β-chains sequenced so far[9,10,12,14] are present in the clone (compare Fig. 2).

To deduce the amino-terminal sequence of a β-chain of the same type as that encoded by pII-β-7, we isolated a genomic clone from a DR/Dw 4/4 cosmid library (B. Servenius *et al.*, in preparation) with this cDNA clone as the probe. This cosmid clone, cosII-412, contains a β gene that is related to pII-β-7 according to the following criteria: the 3′-untranslated sequences of the two clones show 90% homology (data not shown). No homology whatsoever is found between the 3′-untranslated portions of these clones and clones encoding DR and DC β-chains. The exon encoding the first domain of cosII-412 is highly homologous to the portion of pII-β-7 available for comparison. Also, the amino acid sequences predicted from the two clones are homologous (Fig. 1*b*). The six nucleotide substitutions between the sequenced portions of cosII-412 and pII-β-7 (derived from a DR 3/w6 library) are not unexpected as the polymorphism of the β-chains is almost exclusively localized in the first domain[10].

pII-β-7 and cosII-412 encode β-chains that are distinct from, but homologous to, DR and DC β-chains (Fig. 2). To obtain maximal homology with the latter sequences, a gap of two residues had to be introduced into the amino acid sequence predicted from cosII-412. Accordingly, the acceptor site of the first splice junction in cosII-412 resides in the same codon (+5) as in DC β (ref. 20) and DR β genes (D. Larhammar *et al.*, in preparation), assuming that the same number of amino acids are encoded by the signal sequence exons. The extracellular portions of the β-chains corresponding to pII-β-7 and cosII-412

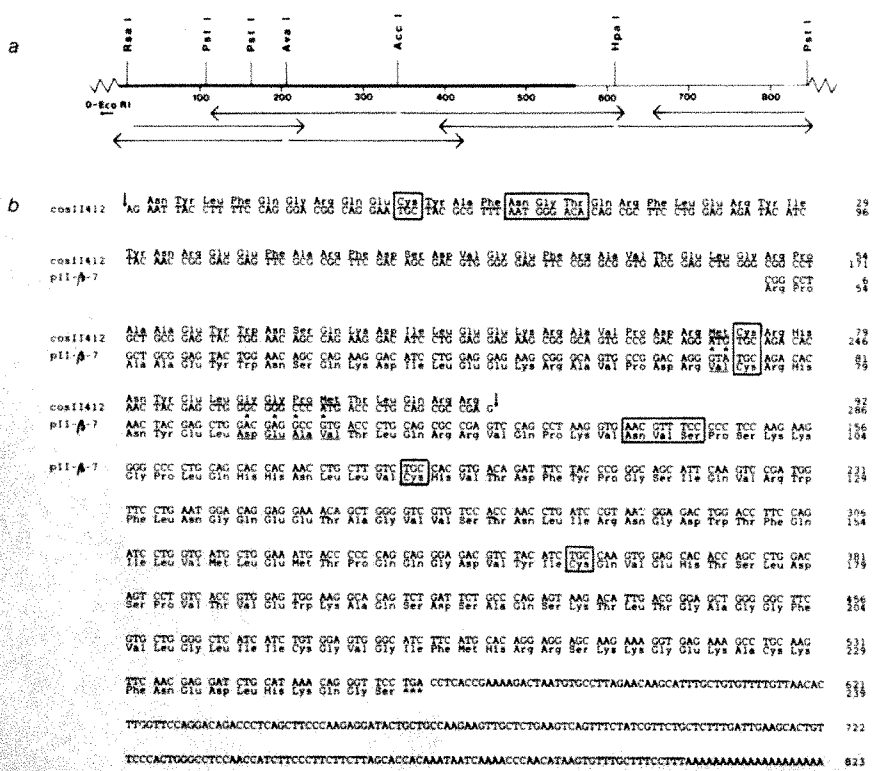

Fig. 1 *a*, Restriction map of the pII-β-7 cDNA insert, with the translated portion indicated by a thick line. The shortest distance from the cloning site (*Pst*I) to the *Eco*RI site at position 0 in pBR322 is indicated. The sequencing strategy is shown by arrows. *b*, The nucleotide and predicted amino acid sequences of the cDNA insert of pII-β-7 and of the first domain exon of cosII-412. Asterisks denote nucleotide substitutions between the two sequences. Amino acid replacements are underlined. The nucleotide sequence was determined according to the procedure of Maxam and Gilbert[22]. Cysteine residues, which by homology to other class II antigen β-chains are disulphide-linked, are boxed, as are two putative attachment sites for *N*-linked oligosaccharides at Asn 19 and Asn 98. The first cysteine residue is numbered 15 in accordance with DR and DC β sequences. cosII-412 was isolated from a genomic library consisting of DNA from an Dw/DR 4/4 individual partially digested with *Mbo*I and inserted into the cosmid vector pHEP (ref. 23). pII-β-7 was used as the probe in colony hybridization. cosII-412, which hybridized strongly to the probe, contained the first domain exon in a 7.3-kb *Hin*dIII fragment, which was subcloned into pUC9 and used for nucleotide sequencing.

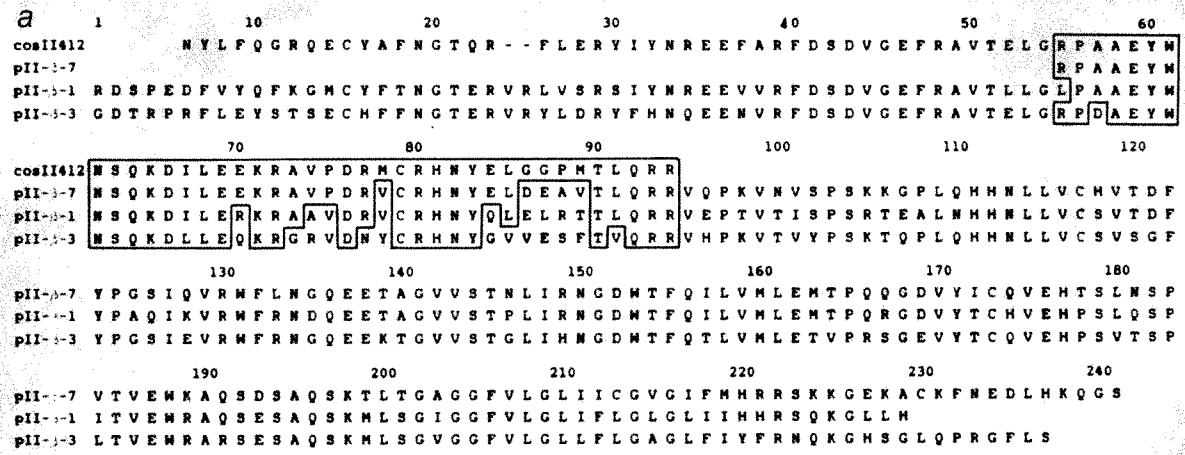

Fig. 2 *a*, Comparison of the amino acid sequences predicted from pII-β-7 and cosII-412 with the corresponding sequences of pII-β-1 (DC)[11] and pII-β-3 (DR)[19]. A gap of two residues was introduced into the sequence predicted from cosII-412 to maximize the homology. Amino acid residues homologous to the cosII-412 β-chain in the portion where this sequence overlaps the pII-β-7 β-chain sequence, are boxed. *b*, Comparison of the partial amino-terminal sequence of an SB β-chain[16] with the predicted amino acid sequences of cosII-412, cosII-102 (ref. 20), pII-β-1 (ref. 12), pII-β-2 (ref. 10), pII-β-3 and -4 (ref. 19) and HLA-DRβ1 (ref. 14). Tyrosine and phenylalanine residues are enclosed in open or shaded boxes. Shaded residues coincide with the tyrosines and phenylalanines present in the SB β sequence.

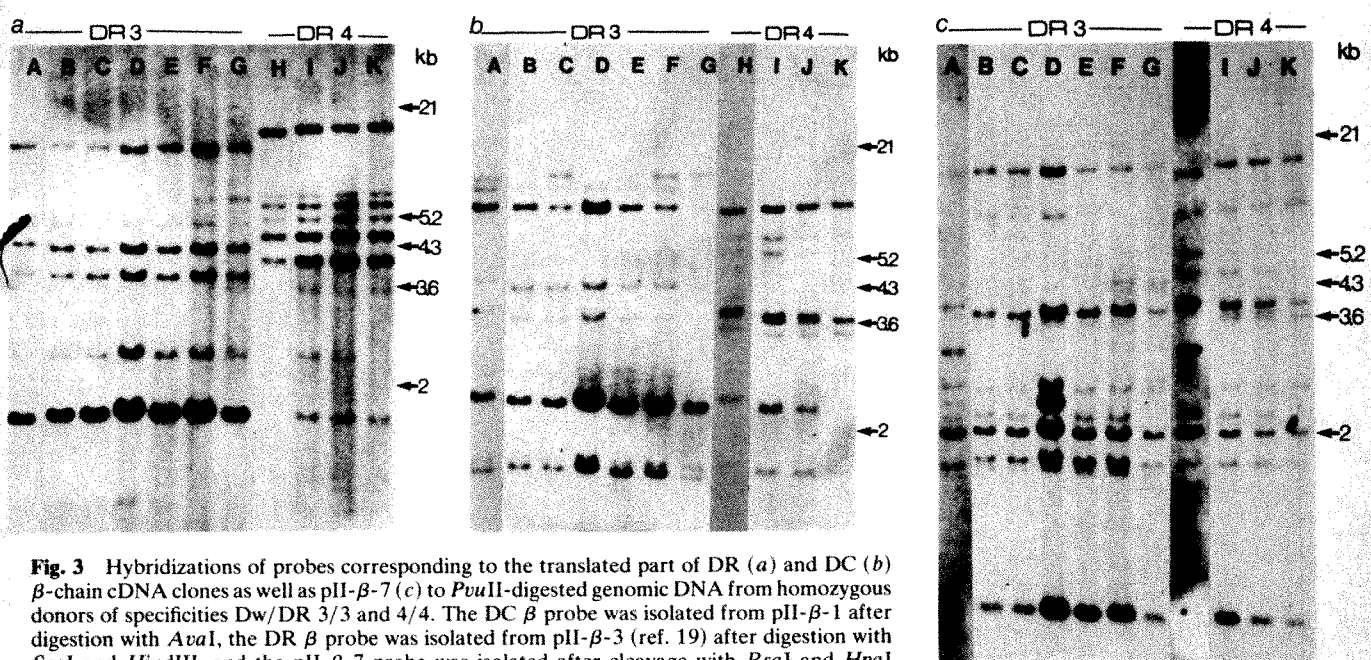

Fig. 3 Hybridizations of probes corresponding to the translated part of DR (*a*) and DC (*b*) β-chain cDNA clones as well as pII-β-7 (*c*) to *Pvu*II-digested genomic DNA from homozygous donors of specificities Dw/DR 3/3 and 4/4. The DC β probe was isolated from pII-β-1 after digestion with *Ava*I, the DR β probe was isolated from pII-β-3 (ref. 19) after digestion with *Sac*I and *Hin*dIII, and the pII-β-7 probe was isolated after cleavage with *Rsa*I and *Hpa*I (Fig. 1). All probes are derived from the translated regions of the three β cDNA clones. The probes were nick-translated (ref. 24) to a specific activity of $5–10 \times 10^7$ c.p.m. μg^{-1}. DNA was isolated from the cells as described previously[25]. DNA samples (10 μg) were digested to completion with *Pvu*II (New England Biolabs) and run on 0.7% agarose gels in 89 mM Tris-borate buffer, *p*H 8.3 containing 2.6 mM EDTA for 600 volt-hours and transferred to nitrocellulose filters[26]. The filters were prehybridized for 3–6 h at 42 °C in 50% formamide, 5 × SSPE buffer (SSPE = 10 mM sodium phosphate *p*H 7.0, containing 1 mM EDTA, 180 mM NaCl), 5 × Denhardt's solution[27], 0.02% of salmon sperm DNA and 0.2% SDS. Radioactively labelled cDNA fragments were added ($1–2 \times 10^6$ c.p.m. ml^{-1}) in a solution of 50% formamide, 5 × SSPE buffer, 1 × Denhardt's solution, 0.02% salmon sperm DNA, 0.2% SDS and 10% dextran sulphate. After hybridization at 42 °C for 16–24 h, the filters were washed twice in 2 × SSPE buffer, 0.2% SDS for 5 min at room temperature and twice in 0.2 × SSPE buffer, 0.2% SDS for 20 min at 55 °C. The filters were then autoradiographed with intensifying screens at −70 °C.

display approximately 67 and 71% homology to DR and DC β-chain, respectively. The latter two types of β-chains are approximately 66% homologous with each other (Fig. 2*a*). Thus, pII-β-7 and cosII-412 encode a new type of class II antigen β-chain. This is also evident from the predicted structure of the cytoplasmic portion of the pII-β-7 β-chain; it consists of 22 amino acids in contrast to the cytoplasmic portions of DR[14] and DC[10,12,20] β-chains, which are composed of 16 and 10 residues, respectively.

A partial amino-terminal sequence of an SB β-chain has been determined, locating the positions of five tyrosine and two phenylalanine residues[16]. Except for one tyrosine, all these residues coincided with tyrosines and phenylalanines in the amino acid sequence predicted from cosII-412 (Fig. 2*b*). Moreover, no additional residues of these types were found in the sequence. In contrast, of the seven residues identified in the SB β-chain, only two (or three) tyrosines coincided with tyrosines in DC β-chains and only one phenylalanine with the corresponding residue in DR β-chains. One DR β-chain sequence also displayed one of the tyrosines found in the SB β-chain. The DC and DR β-chains also contained additional tyrosine and phenylalanine residues at the amino terminus. We suggest, therefore, that cosII-412 and pII-β-7 encode SB β-chains (or chains closely related to SB β).

The SB locus is located at some distance towards the centromere from the DR and DC loci, which are tightly linked[4]. To study the degree of linkage between the gene corresponding to pII-β-7 and the DR locus, we used pII-β-7 as a hybridization probe to genomic DNA of HLA D/DR homozygous individuals. For comparison, hybridizations were also carried out with DR and DC β-chain probes. The DNA samples (seven of which were typed to be Dw/DR 3/3 and four to be Dw/DR 4/4) were digested with *Pvu*II. The experimental conditions chosen for the hybridizations were such that no, or only slight, cross-hybridizations occurred with the three probes. Figure 3 shows that the banding patterns obtained were distinct and different. The probe corresponding to the translated portion of a DR β-chain clone gave rise to virtually identical patterns for all the DR 3/3 homozygous samples (Fig. 3*a*). It should be noted that the faint band of ~6 kilobases (kb) was present in all samples and that the figures are composites from several autoradiograms, thus making perfect alignments of the samples difficult to achieve. The DR 4/4 samples gave a pattern distinct from that of the DR 3/3 samples. However, apart from a weakly hybridizing band of 2.2 kb which was absent from one sample (Fig. 3*a*, lane K) all DR 4/4 homozygous samples appeared identical.

The DC β probe also gave rise to hybridization patterns that conformed well to the typed DR specificity of the sample. Thus, all seven DR 3/3 homozygous samples appeared identical, apart from one sample lacking a 9.2-kb band (Fig. 3*b*, lane D). This result agrees with the observation that the hybridization patterns of DR 4/4 homozygous samples, although different from those of the DR 3/3 samples, were also identical to each other. It is obvious that the 2.2-kb band, absent from lane K of Fig. 3*b*, was the result of cross-hybridization of the DC and DR β-chain probes to the same genomic sequence (compare Fig. 3*a*, lane K).

The hybridization patterns obtained with pII-β-7 as the probe were quite similar for the DR 3/3 and DR 4/4 samples (Fig. 3*c*). In addition, the variability between identical DR samples was of the same magnitude as between the DR 3/3 and DR 4/4 samples. Thus, the hybridization patterns did not correlate well with the DR specificity of the samples. This indicates that the locus corresponding to pII-β-7 and cosII-412 is located at some distance from the DR locus. This finding is perfectly compatible with the structural similarity between the β-chain encoded by cosII-412 and an isolated SB β-chain discussed above. We conclude, therefore, that pII-β-7 and cosII-412 code for SB β-chains (or chains closely related to SB β-chains).

After submission of this manuscript, Roux-Dosseto *et al.* reported the identification and sequence of a cDNA clone suggested to correspond to an SB β-chain[21]. The β-chain predicted from this clone is highly homologous to that deduced from pII-β-7, except in the cytoplasmic portion, which only consists of 12 residues. Whether the clone described by Roux-Dosseto *et al.*[21] is derived from the same gene as the clones described here remains to be investigated.

We thank Ms Anita Morén for technical assistance, Ms Elisabetta Rossi for assistance with the computer analyses and Drs E. Möller, A. Svejgaard and E. Thorsby for providing us with homozygous typing cells. This study was supported by grants from the Swedish Cancer Society, King Gustaf V 80-years fund and the Marcus Borgström fund.

Immortalization of monkey epithelial cells by specific fragments of Epstein–Barr virus DNA

Beverly E. Griffin & Loraine Karran

Imperial Cancer Research Fund, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX, UK

Epstein–Barr virus (EBV) is unique among the DNA tumour viruses by virtue of its association with two human malignancies, Burkitt's lymphoma and nasopharyngeal carcinoma (NPC), the former a tumour of B lymphocytes and the latter encompassing low-differentiated epithelial cells of the nasopharynx[1–4]. A viral gene product has not been definitively linked to these malignant diseases, although an EBV nuclear antigen(s) (EBNA) seems to be ubiquitous in EBV-infected cells; indeed, the detection of EBNA by immunofluorescence is often taken as an indication of the presence of the viral genome[5,6]. As part of a study to investigate which part of the EBV genome is responsible for transformation and whether the same mechanism of cellular transformation is involved in the case of B lymphocytes and epithelial cells, we have tried to establish whether a detectable cellular alteration(s) can be induced in primate epithelial cells by the presence of a specific region of the EBV genome. We report here that it can—the result is immortalization of the cells.

A hybrid cosmid library was made that encompasses the viral genome within six fragments (see Fig. 1), using partially cleaved *Bam*HI fragments from B95-8 virion DNA cloned into the cosmid pHC79 (ref. 7). These recombinants, together with virion and episomal[8] EBV DNAs, and suitable controls, were used to transfect a mixture of cells derived from African green monkey (*Cercopithecus aethiops*) kidneys (AGMK cells). After

~3 months in culture, very small, densely staining cell populations were observed in several of the experiments but the two dishes that contained cells transfected with DNA from cosmid clones designated p13/p33 and p31 were readily distinguishable from the others by the quantity and size of 'foci' in them. Details of the transfection experiments, and data derived from them, are given in Fig. 2. The results illustrated in Fig. 2 were confirmed by examination of unstained dishes under the light microscope.

Individual foci were selected from AGMK cells transfected with p13/p33 and p31 DNAs, as well as from dishes containing cells transfected with either calf thymus (control) or clone p65 DNAs. Foci were transferred manually to fresh dishes (50 mm) and fed weekly. Whereas none of the small foci from the calf thymus or p65 experiments grew, nine cell lines were established from foci (out of the 10 selected from each experiment) derived from the p13/p33 or the p31 dishes. Thus, only AGMK cells exposed to EBV DNA fragments from a specific region of the viral genome could be propagated in culture. Several of the cell lines have been studied further. Five of them subdivided at a 1:10 dilution weekly have been kept for more than a year in culture (corresponding to at least 200 generations) with no apparent change in morphology or growth rate, as determined by regular examination by light microscopy. By morphological and histological examination the cells have been shown to be epithelial in type (see Fig. 3*a–c*). Cells from the 13/33 f4 and the 31 f4 experiments, screened by immunofluorescence, show the presence of intermediate filaments typical of epithelial cells[9,10] (see Fig. 3*d, e*). Whereas microscopic examination of the original AGMK cells revealed cells characteristic of elongated and cuboidal epithelium, and of fibroblasts, the immortalized cells exhibited only the simple cuboidal morphology (Fig. 3*b, c*). Thus, it seems that a subpopulation of monkey epithelial cells has been immortalized by transfection with the EBV DNA fragments.

All cell lines examined proved to be capable of growing for a limited time in low serum. Cell growth in either normal (5%) or low (0.5%) concentrations of fetal calf serum (FCS) was independent of serum concentration during the first month in culture, cells being subdivided at a 1:10 dilution weekly and cell counts determined. After 2 months, the growth rate in low serum slowed to about one-half that of the cells growing in normal serum. Qualitatively similar results were obtained when the cells were plated into semi-solid (agar) media, that is, initially the cells divided and small visible colonies, containing a number of greatly enlarged cells, were observed within 3–4 weeks. These colonies generally then ceased to undergo further division, but ›eing isolated and re-plated onto plastic, they resumed ion and grew normally. In additional experiments, cells ı early passages of a number of the lines, as well as control AGMK cells, were injected intraperitoneally into young nude mice (10^6 cells per animal); no tumours were apparent a year later. (Similar experiments using late passage cells are in progress.) These observations all indicate some dramatic alteration in the growth properties of the cells, effected by specific fragments of EBV DNA, that are not sufficient, however, to produce a malignant phenotype.

As a permanent change seemed to have been produced in the AGMK cells following transfection with either of two defined, partly overlapping fragments of the EBV genome, it remained to be determined whether the continued presence of the virus-derived DNA could be observed. Therefore, total chromosomal DNA from four of the established cell lines was applied directly to nitrocellulose filters and probed with either ^{32}P-labelled B95–8 virion DNA, or cloned fragments of EBV DNA, in order to detect viral DNA sequences. The presence of EBV-related sequences was observed in all four cell lines analysed, but not in the calf thymus DNA used as a control (data not shown). To examine further the nature of EBV DNA sequences in the cell lines, cellular DNA was cleaved with the *Bam*HI restriction enzyme and the resulting fragments were analysed by established methods[11]. Specific fragments that hybridized to viral DNA were observed (Fig. 4); the patterns

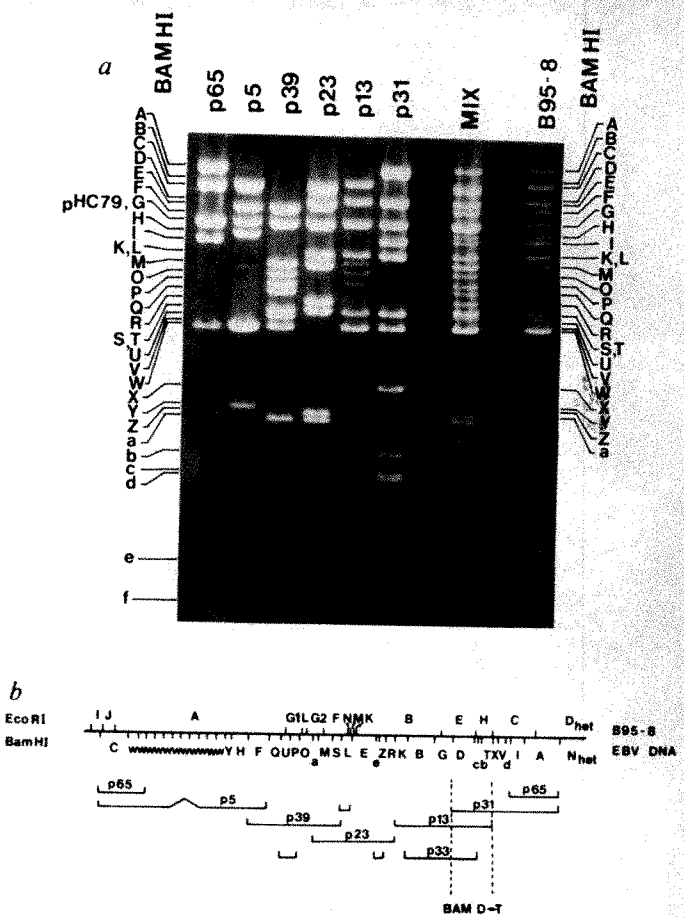

Fig. 1 ***a***, Cloned large fragments of EBV DNA. Virion EB DNA[22] (5 μg) from B95-8 marmoset cells was partially digested with *Bam*HI, and fractionated by neutral sucrose density gradient centrifugation to reduce contamination with small fragments. DNA fragments of ~40 kilobases (kb) were ligated to the *Bam*HI-cleaved cosmid pHC79 DNA (which had been dephosphorylated with alkaline phosphatase), and the resulting hybrid DNAs were cloned according to the procedure of Hohn[23]. Isolated clones were initially analysed by the 'dot-blot' method using individually the large *Eco*RI fragments A to G (ref. 24), radioactively labelled with ^{32}P according to Rigby *et al.*[25], as probes. DNAs from clones that yielded results consistent with the known physical map of EBV DNA were further analysed by electrophoresis on 0.8% agarose gels in Tris-acetate buffer in the presence of ethidium bromide and visualized with UV light, after treatment with *Bam*HI. A 'library' was selected, from among 780 clones analysed, which consisted of six clones designated p65, p5, p39, p23, p13 and p31, as shown. A mixture of the cloned DNAs (MIX) produced a pattern that was qualitatively indistinguishable from the viral (B95-8) DNA. The location of known fragments (A to e) and pHC79, which co-migrates with *Bam*HI G, are indicated; the presence of the latter was confirmed by hybridization against DNA from a clone of *Bam*HI G fragment (data not shown). In addition, a previously unknown fragment, *Bam*HI f, was observed in the clone p23. (The p13 clone, shown here, contained an impurity which was subsequently removed by standard procedures before proceeding to the transfection studies.) ***b***, Schematic diagram showing the location of DNA from cosmid clones p65, p5, p39, p23 and p31 relative to the *Eco*RI and *Bam*HI physical maps of the 170-kb linear EBV virion DNA[26,27]. The location of DNA from another clone, p33, is also indicated. (An original 'mini-prep' analysis of clone p33 mistakenly suggested that it contained *Bam*HI R; it was therefore used in transfection experiments (Fig. 2) together with p13 in order to provide overlap information with p23. Its corrected sequence, based on hybridization analysis, is shown.) The dashed vertical lines indicate the 9-kb sequence (*Bam* D→T) which clones p13 and p31 have in common. Contiguous sequences from these two clones comprise about one-third of the viral genome.

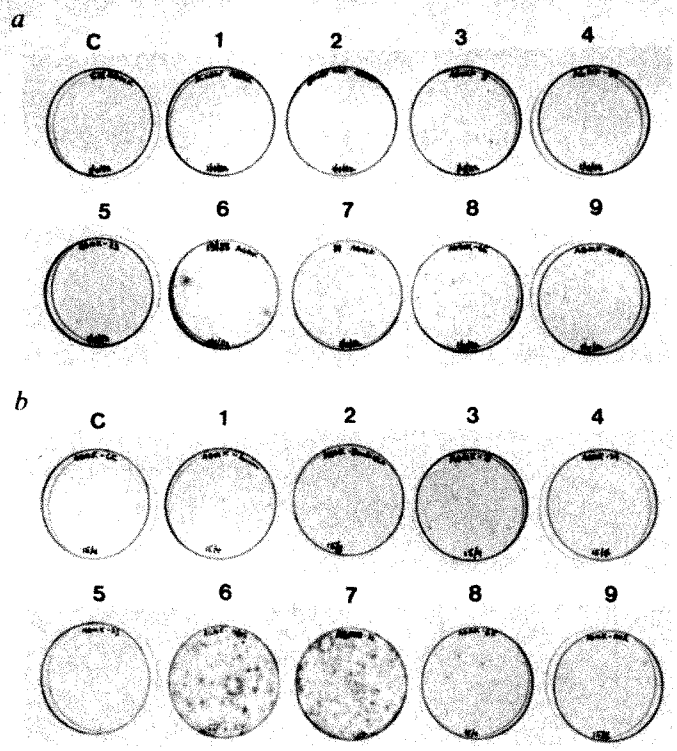

Fig. 2 Dense focus assay of AGMK cells exposed to different fragments of EBV DNA. Subconfluent dishes (50 mm) of early passage AGMK cells were transfected with EBV DNA as indicated below, in the presence of calf thymus carrier DNA (5 μg per dish) and calcium phosphate[28]. Cells were left for 6 h at 37 °C in Dulbecco's modified Eagle's medium (DMEM)–3% glutamine–5% fetal calf serum, then the medium was removed and fresh medium added. After 6 weeks in culture, with weekly changes of medium, cells on each dish were trypsinized and re-plated at a 1:5 dilution onto 50-mm dishes. Thereafter, cells were grown at 37 °C and the media were changed weekly. Individual dishes shown contained AGMK cells transfected with calf thymus (carrier) DNA alone (C) or with linear virion DNA[22] (1); episomal DNA[8] from Daudi cells (2); DNA from clones p5 (3), p39 (4), p23 (5), p13+p33 (6), p31 (7), and p65 (8); and a mixture of cloned DNAs (9). After subculturing, the dishes were left for 4 weeks in culture and 'foci' (*a*) were visualized using Leishman's strain. Whereas aggregations of cells or minor foci were observed at this time in a number of cases, notably among those cells transfected with DNA from the clone p65, p31 or with a mixture of all the cloned DNAs, large distinct foci were observed only in the dish of AGMK cells transfected with the p13/p33 DNA clones. After a further 2 weeks in culture (*b*), large densely growing cell colonies were evident in both the p13/p33 (6) and p31 (7) experiments. EBV DNA was used at a concentration of 5 μg per dish, except in the 'mix' experiment (9), where the total amount of viral DNA was ~25 μg. Failure to form foci in the latter experiment may be a consequence of 'poison sequences' in the cosmid at the concentration used[29].

obtained were not observed when uncleaved material was subjected to similar analyses. In very early passage cultures of 13/33 f4 cells, four bands hybridized to viral DNA (Fig. 4*a*); in later passages of the same cell line, the two largest bands were replaced by a single band having an electrophoretic mobility intermediate between the *Bam*HI co-migrating fragments B/C and D/E (see Fig. 4*b–d*). No further change in the DNA was observed in cells carried for more than a year *in vitro*. These data suggest that some sequence alteration may have occurred between the initial integration event(s) and the establishment of the cells in culture. The two smallest fragments initially observed (Fig. 4*a*) may be derived from monkey DNA as, unlike the larger fragments, their hybridization with EBV DNA could be competitively inhibited by prehybridization with excess cold AGMK DNA. Although cross-hybridization with monkey DNA has not previously been reported, it is well documented that Epstein–Barr virion DNA has regions of homology with a variety of other eukaryotic DNAs[12,13].

Examination of the 13/33 and 31 cell lines for the expression of EBNA proved negative, even though the genetic information for this antigen could at least theoretically have been present in the 13/33 lines (but not in the 31 lines)[14]. Negative results for EBNA were also obtained in the laboratories of G. Klein and D. Crawford (personal communications).

The results of our experiments are consistent with the notion that a specific sub-genomic region of the Epstein–Barr viral

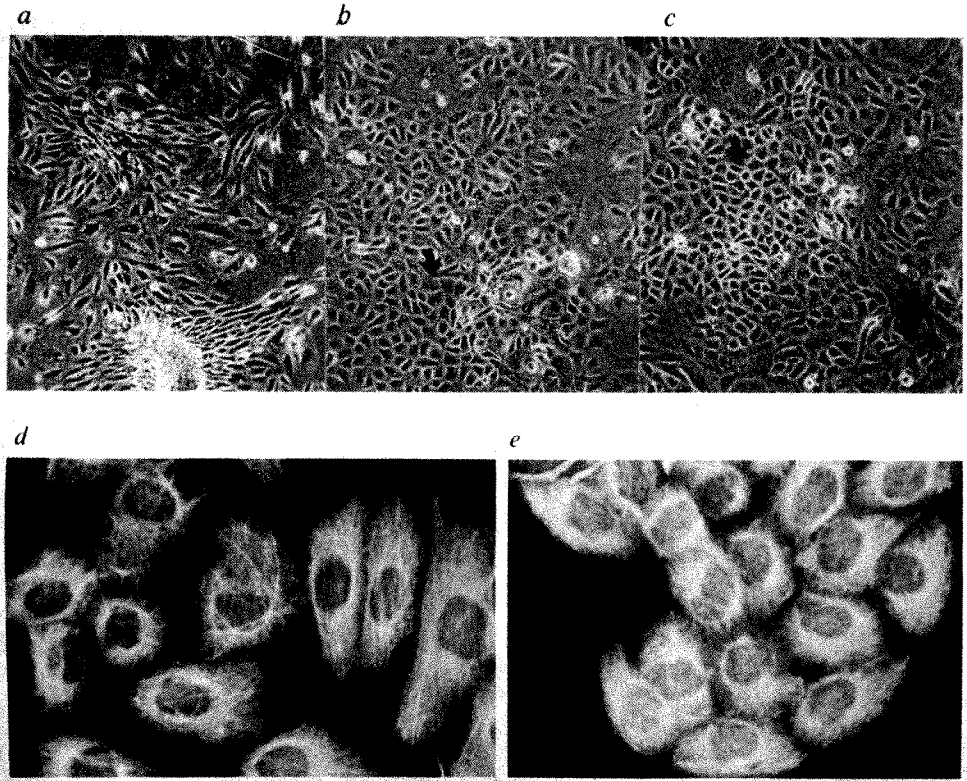

Fig. 3 Morphology of immortalized cells. *a–c*, Light micrographs showing heterogeneous population of cells observed in an early culture of AGMK cells (*a*) and in dishes containing the cuboidal epithelial cells present in the line 13/33 f4 after 14 (*b*) or 34 (*c*) weeks in culture. 13/33 f4 cells examined at an earlier time (4 weeks) showed no obvious morphological differences from the 14- or 34-week cultures. Living cells shown by phase-contrast optics. ×48. *d*, *e*, Immunofluorescent staining with the monoclonal antibody LE61 which recognizes kidney epithelium[9], showing the tonofilament organization of stained cells. Subconfluent cells from the 31 f4 cell line (*d*) are shown, together with the typical close-packing arrangement of rapidly growing cells (*e*), as exemplified by cells from the 13/33 f4 line.

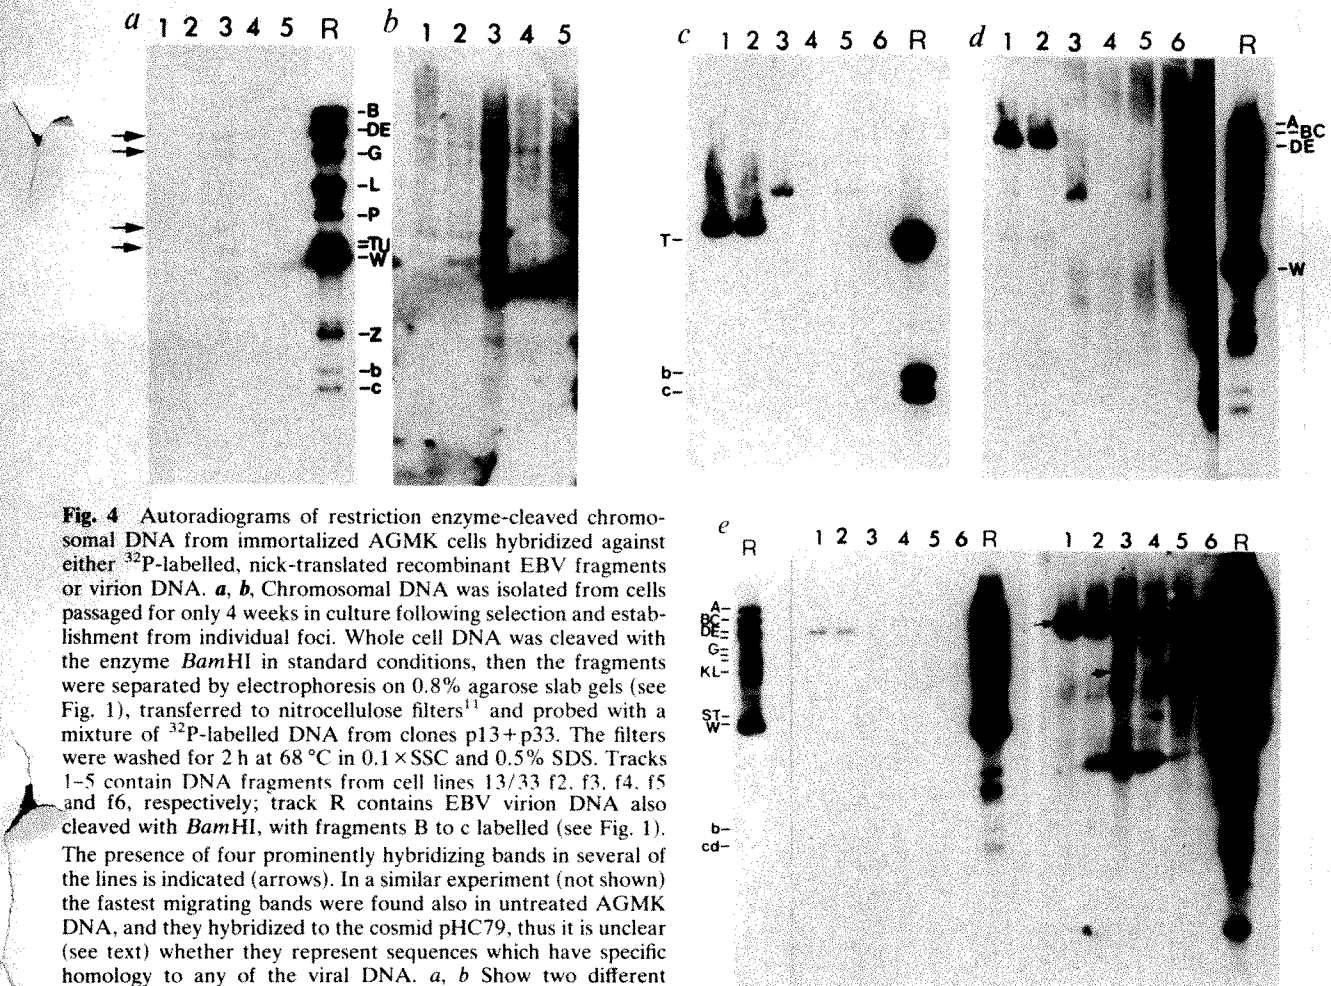

Fig. 4 Autoradiograms of restriction enzyme-cleaved chromosomal DNA from immortalized AGMK cells hybridized against either ^{32}P-labelled, nick-translated recombinant EBV fragments or virion DNA. ***a***, ***b***, Chromosomal DNA was isolated from cells passaged for only 4 weeks in culture following selection and establishment from individual foci. Whole cell DNA was cleaved with the enzyme *Bam*HI in standard conditions, then the fragments were separated by electrophoresis on 0.8% agarose slab gels (see Fig. 1), transferred to nitrocellulose filters[11] and probed with a mixture of ^{32}P-labelled DNA from clones p13+p33. The filters were washed for 2 h at 68 °C in 0.1×SSC and 0.5% SDS. Tracks 1–5 contain DNA fragments from cell lines 13/33 f2, f3, f4, f5 and f6, respectively; track R contains EBV virion DNA also cleaved with *Bam*HI, with fragments B to c labelled (see Fig. 1). The presence of four prominently hybridizing bands in several of the lines is indicated (arrows). In a similar experiment (not shown) the fastest migrating bands were found also in untreated AGMK DNA, and they hybridized to the cosmid pHC79, thus it is unclear (see text) whether they represent sequences which have specific homology to any of the viral DNA. *a*, *b* Show two different time exposures. In the longer exposure (*b*), minor bands can be observed, particularly in track 3 which corresponds to material from the cell line 13/33 f4. ***c***, ***d***, Analysis of DNA from cells passaged continuously for at least 6 months in culture. Tracks 1–5 contain *Bam*HI-cleaved whole cell DNA from lines 13/33 f4, f5 and f6, 31 f4L and 13/33 (uncloned), respectively, and tracks 6 and R contain cleaved DNA from control AGMK cells and EBV virions, respectively. In *c*, the probe was the nick-translated EBV fragment *Eco*RI H, carried on plasmid pAT153 (ref. 24), which hybridized to EBV DNA *Bam*HI fragments T, b and c, as shown (track R). *d*, The results obtained when the blot was washed at 68 °C overnight in low-salt conditions, then re-probed with nick-translated virion DNA and exposed for a longer time. The strongly hybridizing bands in tracks 1 and 2 (in *c*) are essentially no longer visible, whereas the weakly hybridizing bands (see tracks 3 and 5) remain. In addition, in *d*, a new band having a mobility intermediate between *Bam*HI co-migrating fragments B/C and D/E can be seen, especially in tracks 1 and 2. These data suggest that EBV DNA is present but that the strong bands seen in *c* cannot be exclusively correlated with viral DNA. A comparison of *c* and *d* with *a* and *b* further suggests that some change in sequence may have occurred during the passaging of the cells. Most notable is the apparent loss of the two most slowly migrating bands, with their possible replacement by a single, slowly migrating band in lines 13/33 f4 and f5 (tracks 1 and 2), and a faster migrating band in line 13/33 f6 and uncloned 13/33 cells (tracks 3 and 5). ***e***, An experiment analogous to that described for *c* and *d*, but with ^{32}P-labelled nick-translated virion EBV DNA used as the initial probe. Two exposures are shown, and the major hybridizing bands are indicated by arrows. Whole cell DNA isolated from 13/33 f4 cells after more than a year in culture gave a result (not shown) indistinguishable from that found in track 1, indicating sequence stability and the continued presence of the viral DNA during cell propagation.

genome overcomes the senescence observed in untreated AGMK cells and confers the property of unlimited growth on the monkey epithelial cells in culture. Cells immortalized with the overlapping p13/p33 and p31 fragments, following propagation from isolated dense foci, had a finite capacity to grow in soft agar, however, and failed to produce tumours in whole animal (nude mice) experiments. Thus, it seems that of the multi-stage events necessary for the production of malignant cells[15], not all have occurred in these epithelial cells. Note that normal human B lymphocytes, immortalized by EBV infection, initially also fail to produce tumours in nude mice[16]. The most obvious explanation for these data is that EBV *per se* lacks gnant capacity, and additional 'helper' functions, such as e derived from chemical carcinogens or human oncogenes, necessary for inducing a final, transformed state of the cell. Our experiments have produced cell lines which should allow this conclusion to be explored *in vitro*.

The original choice of AGMK cells as an experimental system was based on the fact that expression of Epstein–Barr viral functions has been observed in many non-human primates[17–19] and that transformation efficiency, a possible reflection of stable integration of heterologous information, might be expected to be high[20]. The main cautionary note to be considered in interpreting our data resides in the fact that an endogenous 'EBV-like' virus has been isolated from a lymphoblastoid African green monkey line (AGM-1106) by zur Hausen and colleagues[21]. While this lymphotropic virus would not be expected to be present in kidney cells, as EBV DNA has never been found in human kidney epithelial cells, it is conceivable that AGMK cells might already carry herpesvirus information that predisposes them to immortalization. The EBV sequences from the overlapping p13/p33 and p31 clones were unique, however, among the recombinant and other DNAs introduced during the experimentation protocol in producing immortalization (see Fig. 2). Competition experiments have shown that these sequences are absent from the original AGMK cells and that they survive in the established epithelial lines. Thus, they are undoubtedly important in the immortalization event.

Similar experiments are being done to study the interaction of fragments of EBV with other primate cells. Preliminary data

using primary kidney cells from common marmosets (*Callithrix jacchus*) and primary human breast cells (studies with N. Wedderburn and S. E. Chang) show that at least one of the EBV cloned DNA fragments (p 31) which confers immortality on AGMK cells, also markedly promotes growth in these cells. As these studies are potentially relevant to the human disease, nasopharyngeal carcinoma, the experimental approach should be extended to a variety of human epithelial cells.

We thank Drs S. E. Chang and C. Rowlatt for advice and help in showing the epithelial character of the cell lines described; Dr E. B. Lane for a generous gift of the monoclonal antibody, LE61; Dr D. Crawford and Professor G. Klein for assaying cells for EBNA expression; Ms E. Björck for assistance with molecular cloning; and A. Leigh-Brown for some of the initial cell work. We also thank Drs A. Harris and T. Lindahl for helpful discussions.

Initiation of translation at internal AUG codons in mammalian cells

Chung-Cheng Liu, Christian C. Simonsen & Arthur D. Levinson

Department of Molecular Biology, Genentech Inc., 460 Point San Bruno Blvd, South San Francisco, California 94080, USA

Initiation of translation of eukaryotic mRNAs typically occurs at the first AUG triplet from the 5′ end of the message, although several notable exceptions have been described[1–3]. Using vectors which efficiently express the gene encoding the surface antigen of hepatitis B virus in monkey cells, we have studied the consequences of inserting ATG triplets in all three reading frames upstream of the usual translational initiation codon of this gene. In agreement with the scanning model for eukaryotic translation initiation[1,2], these additional codons can severely depress the initiation of translation at the 'authentic' start codon, although the extent of inhibition depends on sequences flanking the upstream AUG. Such inhibition can, however, be at least partially suppressed by the presence of a translation termination codon in-frame with the upstream AUG. These results raise the possibility that mammalian ribosomes can reinitiate translation at an AUG codon after previously initiating, and terminating, at an upstream site.

We have used a rapid expression assay to quantify levels of the surface antigen of hepatitis B virus (HBsAg) production

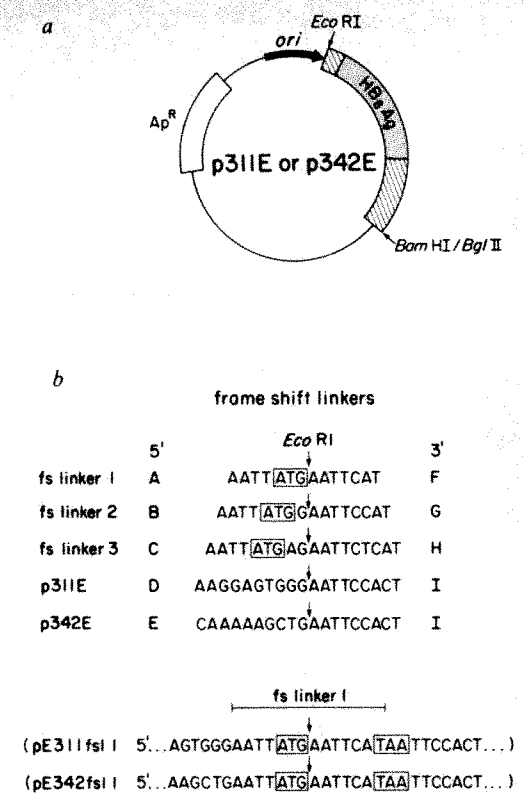

Fig. 1 Construction of pE311fsl and pE342fsl plasmids. The pE311fsl plasmids were derived from p311E (ref. 4), containing the 2,000-bp *Eco*RI–*Bg*III fragment of hepatitis β virus (ref. 9) inserted into plasmid pML (ref. 18) between the *Eco*RI and *Bam*HI sites and following the 311-bp *Eco*RII fragment of SV40 oriented in the early direction. This SV40 fragment spans the replication origin (nucleotides 5,092–160 (ref. 17)) and the early viral promoter[5]. The pE342fsl plasmids were derived from p342E (ref. 4), identical to p311E except that a 342-bp *Pvu*II–*Hin*dIII fragment (nucleotides 5,171–270 (ref. 17)) spanning the SV40 origin was used instead of the 311-bp *Eco*RII fragment. Both plasmids were modified by incompletely digesting with *Eco*RI and filling-in the restriction site using DNA polymerase as described previously (ref. 19). Plasmids were screened for the loss of the *Eco*RI site preceding the SV40 early promoter. Into the single remaining *Eco*RI site immediately following the SV40 promoter were separately inserted the three oligonucleotides, synthesized by the phosphotriester method[20]. These oligonucleotides are bounded by the self-complementary ends of the *Eco*RI site and contain an ATG triplet followed by an *Eco*RI site (*b*). The region spanning the *Eco*RI site used in the construction of every plasmid was directly sequenced using the dideoxynucleotide chain termination method[21] to verify the structure of the linker and the reading frame. *a*, Schematic map of plasmids p311E and p342E. The HBsAg gene is denoted as a shaded box. Nontranslated regions are cross-hatched and the coding region is shown as a stippled box. The position of the SV40 origin/promoter fragment[4,5] is shown. *b*, Sequence of the three oligonucleotide frameshift linkers. The sequences of the oligonucleotide linkers are shown as a 5′ component (A, B, C) and a 3′ component (F, G, H). D, E and I illustrate the sequence at the *Eco*RI site present at the junction of the SV40 and HBV inserts in p311E and p342E (ref. 4). The resulting sequence spanning the *Eco*RI site of pE311fsl-1 and pE342fsl-1 is shown.

directed by mutants of plasmids p342E and pE311 (ref. 4). These pBR322-based plasmids contain the gene encoding HBsAg, positioned behind either of two different, but overlapping, Simian virus 40 (SV40) DNA fragments which contain sequences spanning the viral origin of DNA replication and the early promoter (ref. 5) (Fig. 1*a*). When introduced into COS cells (monkey cells which synthesize SV40 T antigen[6]), plasmid replication ensues with the concomitant synthesis of significant levels of HBsAg mRNA[4,7]. We have previously demonstrated by S_1 nuclease analysis that such mRNA transcribed from both

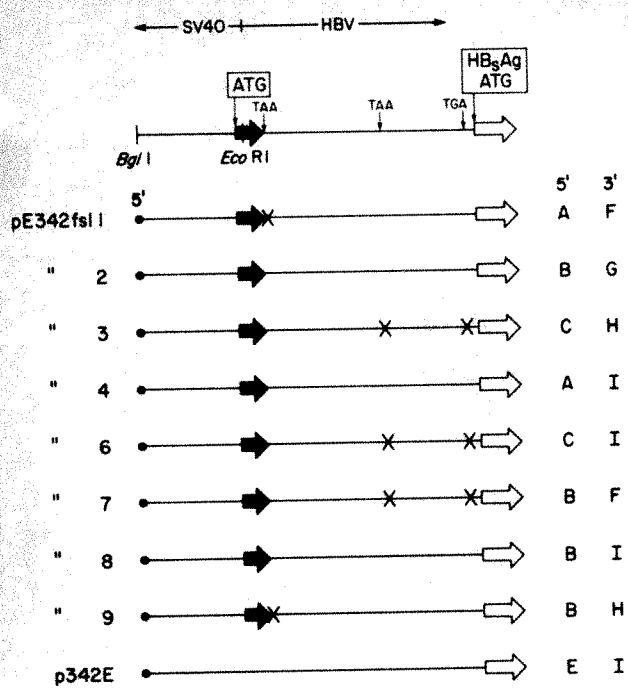

Fig. 2 Structure of the p342E frameshift plasmids. Plasmids p342E, pE342fsl-1, -2 and -3 were digested with *Eco*RI and *Sal*I, the two resulting fragments separated and purified on an acrylamide gel using standard procedures[19]. The additional hybrid plasmids were constructed by ligation of the appropriate fragments. The structure of each was verified by direct determination of the nucleotide sequence across the restored *Eco*RI site[21]. The sequence of the SV40/hepatitis B virus junction is listed as a 5′ and 3′ component. The corresponding nucleotide sequence can be deduced from the information provided in Fig. 1*b*. X, The locations of termination codons in-frame with the linker ATG. The position of the linker ATG and the translation start codon of the HBsAg gene are denoted above the line drawing.

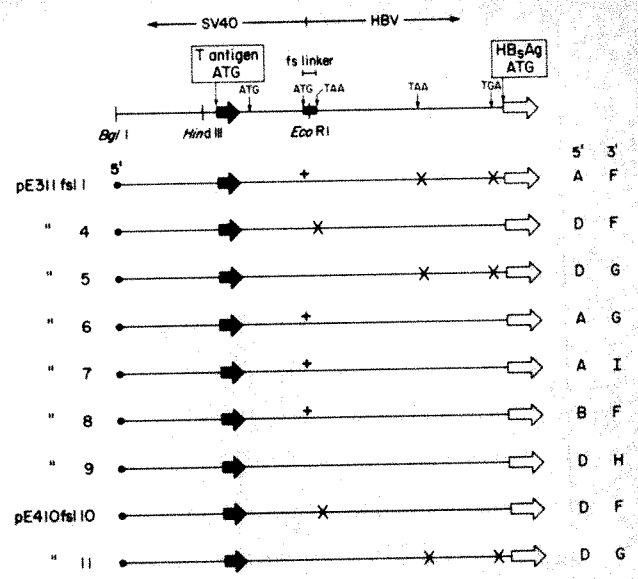

Fig. 3 Structure of the p311E frameshift plasmids. Plasmids p311E and pE311fsl-1, -2, and -3 were treated as described in Fig. 2 and the various combinations constructed as indicated. All junctions at the restored *Eco*RI site were verified by direct sequence analysis. Plasmids pE410fsl-10 and -11 were constructed by digesting p311E with *Bgl*I and *Sal*I, and inserting the 2,400-bp fragment spanning the HBsAg gene between the equivalent sites of p342E (see also Table 2). Symbols are as described in Fig. 2; the presence of an ATG provided by the frameshift linker is indicated by a '+'. The location of the possible termination codons are also shown. The precise structure of the junction can be deduced from the sequences shown in Fig. 1*b*.

plasmids initiates within the SV40 promoter at the expected distance from the TATA box[4] and terminates within HBV sequences 1,100 nucleotides 3′ of the coding region of the HBsAg gene (ref. 7, and C.-C.L., C.C.S. and A.D.L., unpublished data). In pE342, the gene encoding the surface antigen is positioned directly 3′ of SV40 sequences encompassing the complete early promoter[4], such that no AUG triplets precede the translation initiation codon of HBsAg in the mRNA encoding HBsAg (ref. 4 and Fig. 1*a*). COS cells transfected with this plasmid synthesize and secrete significant quantities of HBsAg (ref. 4), a protein of 226 amino acids[8,9] whose synthesis and secretion proceeds without the involvement of a cleavable signal peptide[4,10,11].

To assess directly the effects of upstream AUG triplets on downstream translational initiation, we inserted one of three synthetic *Eco*RI DNA linkers (fsl-1, -2 and -3, Fig. 1*b*), each containing an ATG triplet, into the unique *Eco*RI site of p342E (located at the junction of the SV40 and HBV sequences), to generate pE342fsl-1, pE342fsl-2 and pE342fsl-3. Note that insertion of each of these linkers introduces an upstream ATG triplet in a particular reading frame relative to the 'authentic' translational initiation codon of HBsAg (Fig. 2). These linkers contain the recognition sequence for the restriction endonuclease *Eco*RI; thus after insertion into the vector, a unique *Eco*RI site is restored. This facilitated the construction of hybrid vectors (pE342fsl-4, -6, -7, -8 and -9, Fig. 2), such that the effects of the reading frame of the upstream AUG triplet relative to the 'authentic' HBsAg initiation codon on HBsAg expression could be assessed independently of small sequence differences within the linker (for example, the nucleotide at position +4 relative to the 5′ AUG (ref. 2)) which distinguish the three frameshift linkers (Fig. 1*b*). The effect of these insertions on HBsAg expression was evaluated by transfecting COS cells with the various plasmids and assaying HBsAg in the medium 72 h later. Table 1 illustrates that many of the frameshift plasmids direct the synthesis of HBsAg at levels comparable to p342E, confirming that upstream AUG triplets do not necessarily impair internal initiation[12]. These results extend previous descriptions of this phenomenon[12] since they include AUGs flanked by 'favourable' nucleotides[2,3] at the −3 (A) and +4 position (G) (compare pE342fsl-7 and -9 with p342E). In contrast, plasmids pE342fsl-2, -4 and -8 direct the synthesis and secretion of somewhat lower amounts of HBsAg. As illustrated in Table 1, a common feature of these plasmids with a reduced ability to express HBsAg is the absence of an in-frame translational termination codon intervening between the AUG triplet within the synthetic linker and the AUG triplet defining the start of the HBsAg gene, suggesting that the presence of such a termination codon may enhance internal initiation at the HBsAg gene.

These results demonstrate that, although the presence of an upstream AUG triplet is not in itself sufficient to preclude translation initiation from an internal site (see also refs 13, 14), certain configurations of such a triplet can suppress internal initiation. To see whether flanking sequences could modulate the efficiency with which ribosomes recognize AUG codons as initiation sites[2,3], we examined the effects of inserting an 'authentic' translation initiation codon 5′ of the gene encoding HBsAg, using plasmid p311E (ref. 4), which, although similar to pE342, contains additional sequences 3′ of the SV40 early promoter, including the translational initiation site for SV40 T antigen. As we have reported, plasmid p311E is severely restricted in its ability to promote the synthesis and secretion of HBsAg synthesis[4]. Previous evidence indicated that this block is not a consequence of transcriptional impairment resulting from the absence of the enhancer element associated with the 72-base pair (bp) repeat unit within the SV40 promoter[4], suggesting that HBsAg is translated very poorly, if at all, from its message. This was confirmed by examining HBsAg synthesis from additional plasmid constructions (p232E and p410E). Plasmid

Table 1 Expression of pE342fsl plasmids in COS cells

Plasmid	Linker* sequence 5′	3′	Reading† frame	Termination‡ codon	HBsAg§
pE342fsl-1	A	F	+	+	17,145 ± 1,925
pE342fsl-2	B	G	same	−	9,175 ± 20**
pE342fsl-3	C	H	−1	+	23,620 ± 1,640
pE342fsl-4	A	I	same	−	6,235 ± 1,235
pE342fsl-6	C	I	−1	+	17,440 ± 1,260
pE342fsl-7	B	F	−1	+	19,645 ± 550**
pE342fsl-8	B	I	+1	−	1,980 ± 280
pE342fsl-9	B	H	+1	+	22,580 ± 580
p342E	E	I	−	−	25,785 ± 5,560
p232E‖	E	I	−	−	16,000 ± 600**

Confluent 60-mm dishes of COS-1 cells[6] were transfected in duplicate with 0.5 μg plasmid DNA using a modified DEAE-dextran method[16] as described elsewhere[4]. After 16 h, the cells were washed once with Dulbecco's modified Eagle's medium (DMEM), then fed with 3 ml 7% calf serum in DMEM. Two days later, the cells were re-fed with fresh media. After 24 h, the amount of HBsAg secreted into the medium was quantitated by RIA using the Ausria II kit (Abbott).

* Sequence of frameshift linker as described in Fig. 1 legend.

† Reading frame of linker ATG relative to that of the HBsAg.

‡ Presence (+) or absence (−) of a termination codon in frame with the upstream ATG.

§ Counts per minute as assayed by Ausria II kit, corrected for included negative control. Results are averaged values (with ranges given) obtained from four (** or two) independent experiments.

‖ p232E was constructed by exchanging the proximal promoter sequences of p311 (which lack the SV40 72-bp repeats) with those of pE342 (which lack SV40 T antigen coding information) at the *Bgl*I site. p232E thus contains neither an intact 72-bp repeat nor the translational initiation codon of SV40 T antigen (SV40 sequences extending from the *Eco*RI site at position 160 to the *Hin*dIII site at position 5,171 (ref. 17)).

Table 2 HBsAg expression of pE311fsl plasmids in COS cells

Plasmid	Linker* sequence 5′	3′	Reading† frame	Termination‡ codon	HBsAg*
p311E	D	I	same	−	60 ± 50
pE311fsl-1	A	F	−1	+	1,290 ± 205
pE311fsl-4	D	F	+1	+	2,725 ± 310
pE311fsl-5	D	G	−1	+	1,350 ± 155
pE311fsl-6	A	G	same	−	90 ± 45
pE311fsl-7	A	I	+1	−	460 ± 35
pE311fsl-8	B	F	same	−	20 ± 25
pE311fsl-9	D	H	same	−	125 ± 10**
p410E§	D	I	same	−	30 ± 30
pE410fsl-10	D	F	+1	+	2,895 ± 105**
pE410fsl-11	D	G	−1	+	2,130 ± 180**

Methods of transfection and assay are as described in the legend to Table 1.

* Headings are as defined in Table 1.

† Reading frame of T-antigen translation initiation codon relative to that of HBsAg initiation codon.

‡ p410E was created by the exchange of the proximal SV40 promoter sequences of p342E with the distal promoter sequences of p311E using the SV40 *Bgl*I site. p410E thus contains both SV40 72-bp repeats as well as the translational initiation codon of SV40 T antigen (SV40 sequences from the *Pvu*II site at position 270 to the *Eco*RII site at position 5,092 (ref. 17)).

p232E lacks sequences comprising the 72-bp repeat, but is otherwise identical to pE342. p232E and p342E produce similar levels of HBsAg (Table 1) consistent with the interpretation that the HBV genome contains enhancer sequences capable of complementing those of SV40 (ref. 4), while the insertion of the SV40 enhancer sequences into p311E (generating p410E) fails to restore HBsAg synthesis (Table 2). Thus the inability of p311E to promote efficient HBsAg synthesis appears to result from an extreme inhibitory effect of the SV40 T-antigen translation initiation codon located 231 nucleotides 5′ of the AUG codon which normally initiates HBsAg synthesis.

Protein synthesis initiating at the first AUG (that of T antigen) from mRNA directed by p311E would be expected to produce a hybrid polypeptide consisting of the first 24 amino acids of SV40 T antigen, 52 amino acids specified by the sequence immediately preceding the HBsAg gene, and 226 amino acids of HBsAg (ref. 4). Consistent with this interpretation, intracellular extracts of COS cells transfected with p311E do contain an extended form of HBsAg as determined by radioimmunoassay (RIA) and immunoprecipitation (data not shown), indicating that a polypeptide with HBsAg determinants is synthesized in a form which cannot be secreted. To examine this phenomenon in more detail, the frameshift linkers were incorporated into the unique *Eco*RI site of the parent plasmid p311E or p410E (Fig. 1), and pertinent hybrid plasmids were prepared (Fig. 3). The ability of the various constructs to promote HBsAg synthesis was determined by assaying the medium of transfected COS cells 72 h after DNA administration.

Table 2 illustrates that, as with pE311, no secreted HBsAg is observed with any frameshift linker plasmid expected to generate a fused T antigen/HBsAg polypeptide. In marked contrast, however, significant levels of HBsAg are synthesized from those plasmids which contain an in-frame translational termination codon following the translational initiation codon of SV40 T antigen. This effect was independent of the presence of an AUG triplet within the linker sequence (compare pE311fsl-1 with pE311fsl-5). Specifically, consider that plasmids pE311fsl-6, -8 and -9 all produce less than 1% control levels (that produced by p232E) of HBsAg. These three plasmids are not identical, yet in each the 5′ AUG is present in the same reading frame as the surface antigen AUG, with no intervening in-frame termination codons. Plasmid pE311fsl-7 produces less than 3% of the control level of HBsAg; like the others it lacks an in-phase termination codon, but differs by having the SV40 T antigen initiator AUG in the second reading frame relative to the surface antigen AUG. In contrast, those plasmids (both p311E and p410E-based) in which an in-frame termination codon intervenes between the 5′ AUG and the AUG encoding the first amino acid of HBsAg direct the synthesis of significantly more HBsAg. Interestingly, the presence of an in-frame translational termination codon following the upstream AUG does not restore levels of HBsAg produced by the pE311 vectors to those produced by p342E or p232E (compare Tables 1 and 2). This could be due to the inability of a termination codon to promote the highly efficient use of a downstream initiation codon; alternatively the structure of the hybrid T antigen/HBsAg mRNA may preclude efficient translation of the HBsAg gene.

It has previously been proposed that nucleotides in positions −3 (A) and +4 (G) facilitate recognition of the AUG codon by eukaryotic ribosomes[2]. Our results suggest that additional sequences may be involved in this process, since internal initiation occurs much less frequently when an 'authentic' AUG is positioned upstream of the HBsAg gene (pE311 and pE410-based vectors) than when synthetic AUGs conforming to these specifications are present upstream (pE342-based vectors). The nature of such sequences is uncertain, but the possibility remains that a 'functional' equivalent of a ribosome binding site exists, despite evidence that most mRNAs do not reveal any indication of a specific base-pairing ability between their 5′ non-coding segments and the 3′ terminus of 18S rRNA (ref. 15).

The fact that internal initiation at an otherwise suitable AUG triplet can be thoroughly suppressed by an upstream AUG codon lends strong support to the scanning model for eukaryotic translation initiation[1,2], and is inconsistent with the concept that ribosomes bind directly to AUG initiator codons in mRNA irrespective of their proximity to the 5′ terminus[12]. In contrast to previous suggestions that internal initiation can occur only when upstream AUG triplets are flanked by unfavourable nucleotides[2], our results suggest that reinitiation of translation can occur after the efficient utilization of upstream AUG codons, provided translation has been terminated before the ribosome has reached the internal AUG. It is unclear what factors dictate the efficiency with which such reinitiation occurs; this may be governed to some extent by the position of the termination codon relative to the flanking AUG codons. The fact that internal initiation does not occur in the absence of such a termination codon in the pE311-based vectors strongly argues that initiation at the internal AUG triplet (in those vectors

containing an intervening termination codon) is not mediated by ribosomes which 'escaped' initiation at the upstream site[2], but rather by true reinitiation, although we stress that in a general sense the two models are not incompatible with one another. For example, internal initiation at a site preceded by an efficiently utilized AUG codon may proceed only when translation from the upstream site has first terminated. However, in those instances where only inefficiently recognized upstream AUG triplets are present, an in-frame termination codon would not be required for efficient translation at the internal AUG, since migrating 40S ribosome subunits may simply bypass a weak AUG. In view of the observation that in-frame termination codons almost always follow upstream AUGs in those messages where translation initiates internally, it has been proposed that such terminators may function to facilitate the early return to circulation of those ribosomes which initiate at the upstream site[2]. The prospect that ribosomes may not be released immediately after translation termination, but rather continue scanning for at least some distance, provides an additional rationalization for this observation, and suggests a mechanism by which polycistronic transcripts may function in mammalian cells.

We thank Y. Gluzman for COS-1 cells, Mark Vassar for the preparation of the oligonucleotide linkers, and J. Souder and D. Eaton for technical assistance.

Eukaryotic cells contain genes termed proto-oncogenes (c-*onc*) which have the potential to transform cells in culture and induce tumours *in vivo*. Most of these genes have been identified by their occasional incorporation into retroviral genomes which can act as natural transducing vectors for these and perhaps other cellular genes[1,2]. Cell-derived oncogenes of retroviruses (v-*onc*) are associated mostly with the induction of mesenchymal tumours whereas carcinoma induction is rare[3]. One of these rare carcinoma-inducing viruses is the acutely transforming avian retrovirus MH2 (refs 3–5). Recently we[6,7] and others[8] have shown that this virus carries a novel putative oncogene, v-*mil*, in addition to the known oncogene v-*myc*. While the transforming ability of v-*mil* has not been directly established, we have recently discovered by hybridization analysis that v-*mil* is homologous to v-*raf* (ref. 9), the transforming gene of the murine retrovirus 3611 MSV (ref. 10). Both viruses express the *mil*/*raf* oncogene product as a *gag*-fusion polyprotein[6,11], while the *myc* oncogene of MH2 is expressed via a subgenomic mRNA[12]. Here we report the complete nucleotide sequence of v-*mil* and compare it with that of v-*raf*[34]. The 80% homology between the nucleotide sequences and the 94% homology between the predicted amino acid sequences of the two viral genes clearly indicate that these are the avian and murine forms of the same gene. Comparison of the two sequences with that of the human cellular homologue[13] (T. I. Bonner *et al.*, manuscript in preparation) indicates that v-*raf* has more 3′ untranslated sequences while v-*mil* has additional sequences from two 5′ exons of the cellular homologue. Although the *mil*/*raf* amino acid sequences reveal partial homology to that of the v-*src* product, no tyrosine-specific protein kinase activity is detected for the *gag*–*mil* and the *gag*–*raf* hybrid proteins.

‡ To whom reprint requests should be addressed.

1,416 nucleotides of MH2 proviral sequence containing the complete v-*mil* sequence as well as adjacent viral *gag* p12 sequence at its 5′ end and *myc* gene sequence at its 3′ end were determined and compared with the corresponding v-*raf* sequence in Fig. 1. The 5′ end of v-*mil* is tentatively located at nucleotide 93 or 94. This determination is based on the observation that nucleotides 1–92 are homologous to the *gag* p12 sequence of Rous sarcoma virus (RSV)[14] while the following nucleotides are not. In addition, comparison with the human homologue c-*raf*-1 shows homology beginning at nucleotide 94. Nucleotides 94–265 are specific to v-*mil*. Comparison with the human cellular homologue indicates that they are derived from three exons, one of which is exon 1 of the chicken cellular clone c-*mil*-4 (refs 7, 15) and two of which were not identified in the chicken clone. Homology to the v-*raf* sequence begins at position 266 and with the exception of two small insertions or deletions continues to the termination codon at nucleotide 1,233. The v-*mil* sequence ends 12 nucleotides 3′ of the termination codon. Beyond this point, the sequence matches that of the *myc* cellular homologue, beginning in the first intron 172 nucleotides 5′ of the second exon (M. Linial, personal communication). The v-*mil* sequence contains an insertion of a nucleotide at 1,209 coupled with the deletion of four nucleotides between 1,215 and 1,218 which preserves the reading frame to the termination codon. The human homologue shows no deletions in this region relative to v-*raf*. Thus, the insertions occurred in the mammalian lineage before the divergence of humans and mice or deletions arose in the chicken lineage. Alternatively, the deletions may have arisen during viral replication of MH2 after its acquisition of the v-*mil* sequence. The nucleotide sequence homology over this common coding region is 80% with most of the changes occurring as silent third position changes so that the predicted amino acid sequences have 94% homology.

The MH2 sequence has only one open reading frame capable of producing the *gag*–*mil* polyprotein of molecular weight 100,000. This reading frame corresponds to the reading frame used to produce the *gag*–*raf* polyprotein. Assuming that the *gag* sequence of MH2 is the same as that of RSV (ref. 14), the predicted polyprotein would contain 514 *gag*-specific amino acids and 380 *mil*-specific amino acids with a calculated molecular weight of 97,014. This agrees well with the molecular weight of the *gag*–*mil* p100 protein determined by SDS–polyacrylamide gel electrophoresis, considering the fact that the protein is phosphorylated and possibly glycosylated. There are three potential glycosylation sites of the form Asn-X-(Thr or Ser) in the *mil* sequence at amino acid positions 16–18, 32–34 and 350–352. Of the 19 amino acid differences between v-*mil*

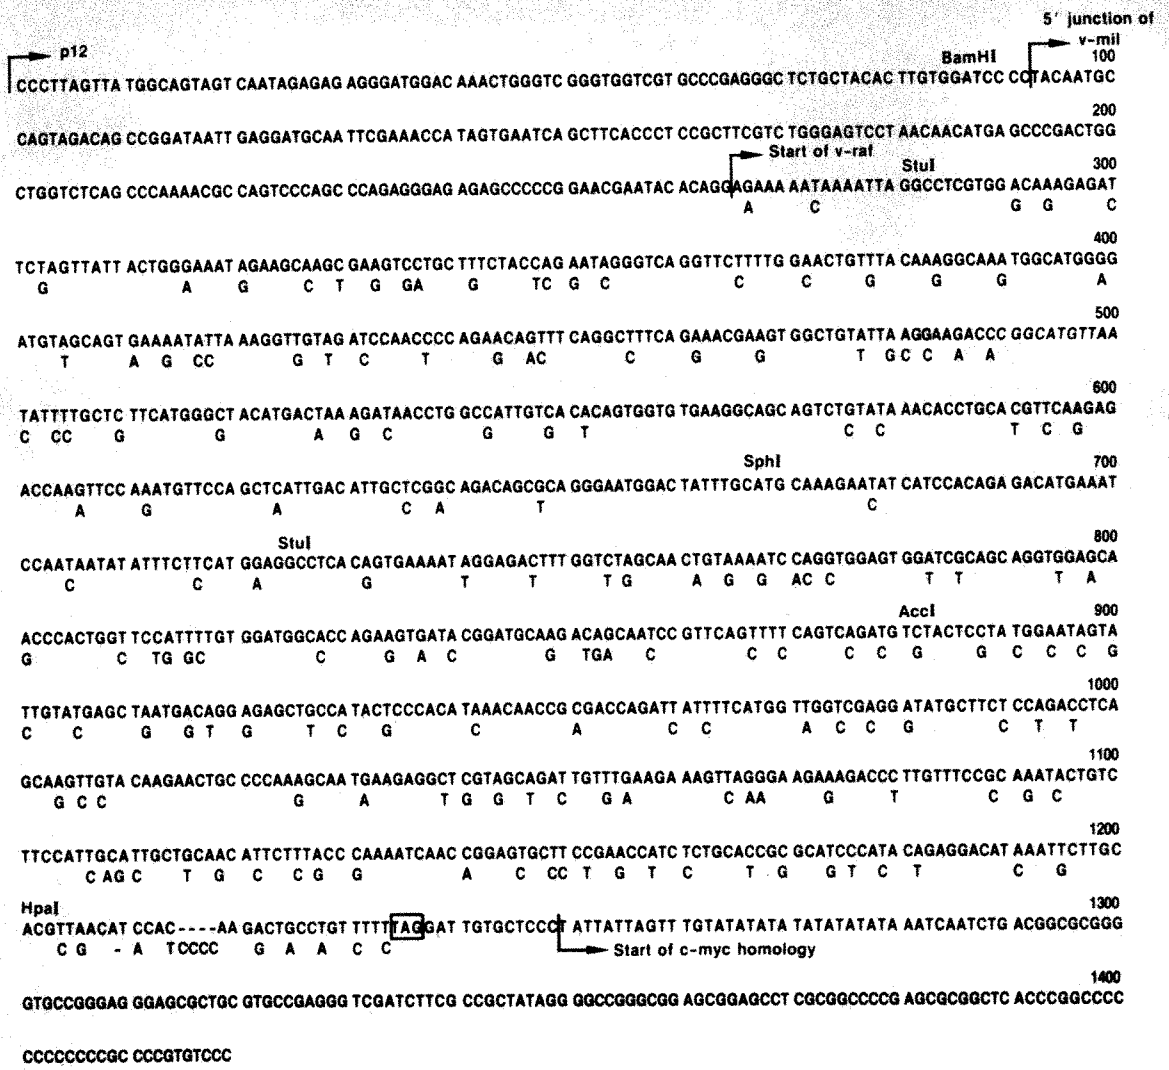

Fig. 1 Nucleotide sequence comparison between the *mil* region of MH2 proviral DNA and v-*raf*[34]. The complete v-*mil* sequence is shown with partial sequences of adjacent viral *gag* and v-*myc* genes. The v-*raf* coding sequence is shown below the v-*mil* sequence at nucleotides where it differs from v-*mil*, and deleted nucleotides are indicated by dashes. The 5′ borders of v-*mil* and v-*raf* are indicated by arrows. The termination codon common to both sequences is boxed. The location of the *mil–myc* junction is indicated by an arrow. Restriction sites used for sequencing of MH2 DNA by the Maxam–Gilbert method[35] are indicated above the nucleotide sequence.

and v-*raf* (Fig. 2), one occurs at a position where v-*mil*, v-*raf* and human c-*raf*-1 differ (T.I.B. *et al.*, manuscript in preparation), 11 occur at a position where v-*raf* and c-*raf*-1 are the same and six occur at a position where v-*mil* and c-*raf*-1 are the same. This result is consistent with mice being more closely related to humans than chickens.

A computer search of known protein sequences revealed that the *mil/raf* oncogene is related to members of the *src* family of oncogenes (see below). The homology is to the carboxy half of the p60 v-*src* product which is associated with tyrosine-specific protein kinase activity. Since the v-*raf* product has not shown any tyrosine kinase activity[11], it was unexpected that this homology exists for the *mil/raf* oncogene. The fact that the v-*mil* protein contains 59 more amino acids than v-*raf* made it important to test the v-*mil* product for kinase activity in comparison with the *raf* protein and with a known tyrosine-specific kinase specified by a member of the *src* family of oncogenes. Figure 3 compares protein kinase activity associated with proteins immunoprecipitated from cells transformed by MH2, 3611 MSV or avian Fujinami sarcoma virus (FSV) carrying the *fps* oncogene[1,2]. Quail embryo cells or rat cells transformed by FSV contain the p140 *gag–fps* protein which is phosphorylated and associated with tyrosine-specific protein kinase activity[16–18] leading to efficient *in vitro* phosphorylation of the p140 protein in a kinase assay (Fig. 3, lanes 1, 3). In the same conditions, very low levels of phosphorus are transferred to the p75 *gag–raf* protein of 3611 MSV or the p100 *gag–mil* protein of MH2 (Fig. 3, lanes 5, 7). Furthermore, phosphoamino acid analysis revealed that this phosphorylation occurred at threonine and serine residues but not at tyrosine residues as in the *gag–fps* protein (data not shown). This agrees with the phosphorylation pattern observed *in vivo* for these proteins[11,17,19]. Whether the low level of *in vitro* phosphorylation of the *raf* and *mil* proteins is an intrinsic activity or due to cellular enzymes present in the immunoprecipitates remains to be determined.

There are three other oncogenes, v-*erb* (ref. 20), v-*fms* (ref. 21) and v-*mos* (ref. 22), which are apparently negative for protein kinase activity yet show homology to the kinase portion of v-*src*. Their cellular locations suggest some diversity of function. The product of v-*erb*-B has been shown to be a membrane glycoprotein[23], possibly functioning as a growth factor receptor[24], whereas v-*fms* encodes a glycoprotein associated with the membranes of endoplasmic reticulum[21]. In contrast, fluorescence assays indicate a diffuse cytoplasmic distribution of the v-*mil*[25] and v-*mos*[26] proteins with v-*mil* possibly being associated with RNA[25]. To determine any similarities among these proteins which may distinguish them from the kinase-positive *src*-related genes, we have compared their amino acid sequences in Fig. 4. Four regions show extensive homology, that is amino acids 18–50, 120–138, 157–183 and 202–247.

Fig. 2 The predicted amino acid sequence encoded by v-*mil* compared with that of v-*raf*. The amino acids are numbered beginning with the first v-*mil* specific amino acid. The v-*raf* sequence is shown below v-*mil* where it differs from v-*mil*, and deletions are indicated by dashes.

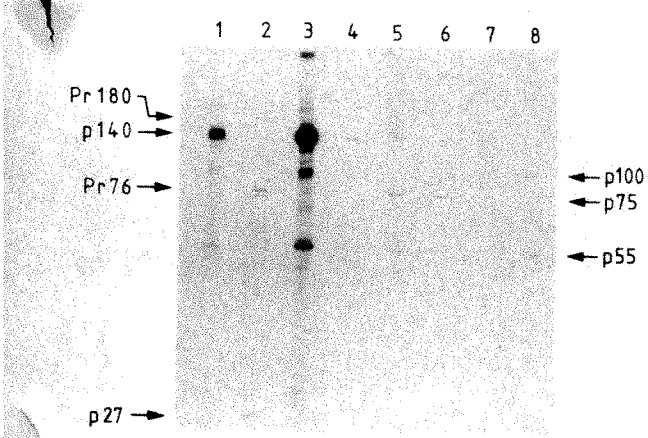

Fig. 3 Protein kinase activity in immunoprecipitates from lysates of cells transformed by FSV, 3611 MSV or MH2. Quail embryo cells transformed by FSV (FAV) (lanes 1, 2), FSV-transformed rat 3Y1 cells[18] (lanes 5, 6), and a nonproducer quail cell clone transformed by MH2 (lanes 7, 8) were used. Lysates were prepared as described previously[16] from unlabelled and ^{35}S-methionine-labelled cells using a lysis buffer containing 50 mM NaCl, 25 mM Tris-HCl *p*H 7.4, 0.5% NP-40, 0.5% sodium deoxycholate, 1 mM EDTA and 400 units ml^{-1} Antagosan (Behringwerke) as a protease inhibitor. Cell lysates were preabsorbed with preimmune rabbit or goat sera and protein A–Sepharose, and immunoprecipitates were then prepared with rabbit antiserum against avian *gag* proteins[6] (lanes 1, 2, 3, 4, 7 and 8) or with goat antiserum against the murine p15 *gag* protein[11] (lanes 5, 6) followed by absorption to protein A–Sepharose. Unlabelled immunoprecipitates were washed with lysis buffer and 20 mM Tris-HCl *p*H 7.4 and were then incubated for 15 min at 30 °C in 50 μl of a kinase reaction solution containing 20 mM Tris-HCl *p*H 7.4 10 mM $MgCl_2$, 1 mM dithiothreitol and 5 μCi [γ-^{32}P]ATP (~2,000 Ci mmol^{-1}; Amersham Buchler, Braunschweig). Reaction products were analysed on a 12.5% polyacrylamide-SDS gel (lanes 1, 3, 5, 7). Immunoprecipitates of ^{35}S-methionine-labelled proteins were analysed in parallel (lanes 2, 4, 6, 8). They include the p140 *gag–fps* protein of FSV (lanes 2, 4), the structural proteins Pr180, Pr76 and p27 of the helper virus FAV (lane 2), the p75 *gag–raf* protein of 3611 MSV (lane 6), and the p100 *gag–mil* protein of MH2 and a possible processing product p55 (lane 8). The autoradiograph was exposed for 12 h.

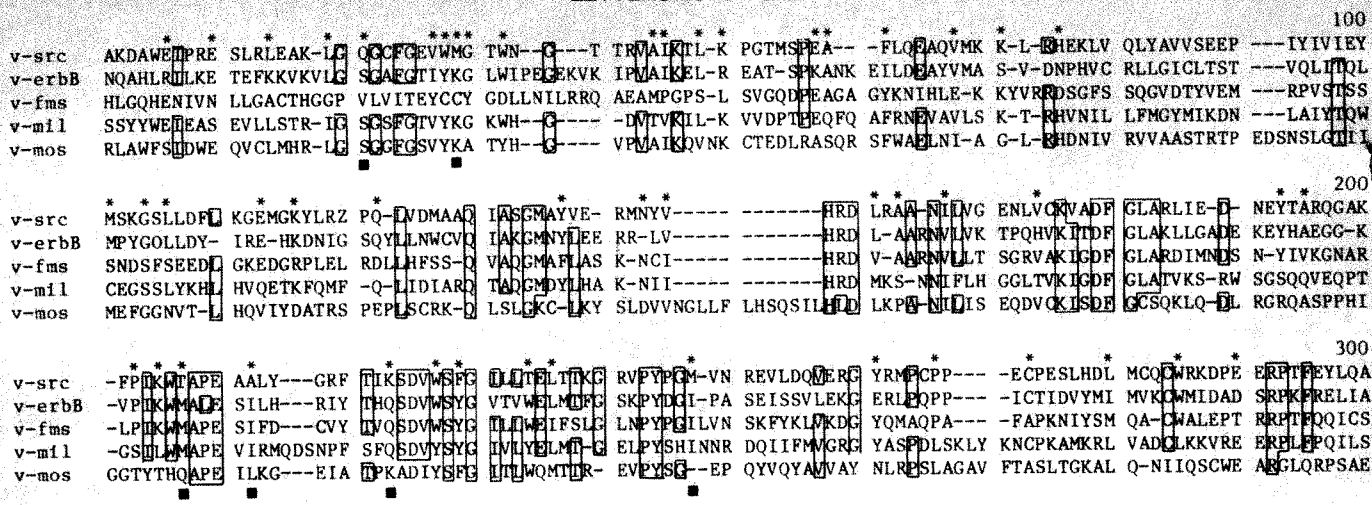

Fig. 4 Alignment of amino acids encoded by non-kinase oncogenes with those encoded by the v-*src* oncogene. The alignment begins at amino acid 71 of v-*mil* and continues to 337. No extensive homology was found outside these limits. Positions at which four or five of the sequences match are boxed. Positions at which three sequences match are indicated by an asterisk above the v-*src* sequence. Positions at which three of the four non-kinase genes match and are different from the kinase positive oncogenes (*fgr, yes, fes, fps, abl* and *src*) are indicated by a closed box below the v-*mos* sequence. The phosphotyrosine of v-*src* occurs at position 193. A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val; W, Trp; Y, Tyr.

Although the other four proteins show substantial homology in the first region, the *fms* sequence shows almost no homology before positions 100–120. The remaining kinase negative proteins (as well as the *raf* protein) contain the sequence Gly-Ser-Gly-X-Phe-Gly-X-X-X-Tyr at positions 21–29 with the serine and tyrosine residues distinguishing them from the kinase-positive oncogenes *src, fgr, yes, fps, fes* and *abl* (refs 14, 27–31). It has been suggested that the Gly-X-Gly-X-X-Gly sequence represents a nucleotide-binding site[32]. A similar sequence, Leu-Gly-Thr-Gly-Phe-Gly-Lys-Val-Val-Glu, is found in v-*fms* about 140 amino acids further towards its amino terminal. The remaining four positions where a common amino acid distinguishes the non-kinase genes, except for *mos*, from the kinase-positive genes occur in the fourth homology region. This region is functionally important as mutagenesis of the alanine at position 211 of v-*src* inactivates its kinase activity[33].

There are three known examples of a retrovirus containing what appear to be two oncogenes: AEV containing *erbA* and *erbB* (ref. 36), E26 containing *ets* and *myb* (refs 37, 38), and MH2 containing *mil* and *myc* (refs 5–7). In none of these cases have both genes been demonstrated to be transforming. The present data demonstrate that v-*mil* has 94% amino acid homology to v-*raf*. When this result is compared with the 96% amino acid homology of v-*raf* to its human homologue c-*raf*-1, it is clear that *mil* is the avian homologue of the murine *raf* gene. As both v-*raf* and the human homologue c-*raf*-1 are capable of transformation, we infer that *mil* is also.

Note added in proof: Close homology has been reported[39] between the *mht* (*mil*) sequence of MH2 and our v-*raf* sequence. The reported *mht* sequence is nearly identical to our *mil* sequence; however, the authors identify the c-*myc* intron sequence as being *mht* 3′ untranslated sequence.

Seismological evidence for shallow crystalline basement in Southern Uplands, Scotland

HALL *et al.*[1] propose that the Southern Uplands contain crystalline rocks of continental affinity at shallow depths (~1–5 km). We suggest that the same seismic data can, in fact, be used to strengthen the argument for a thick accretionary prism[2].

It has been inferred that prehnite–pumpellyite facies metamorphism in the Southern Uplands is related to tectonic burial and rotation of the various slices of the prism as they were accreted during closure of the Iapetus Ocean, and that isograds in the prism are now subparallel to the present day erosion surface[3–6]. The colour alteration of conodonts in the Northern Belt indicates temperatures between 300 °C and 400 °C (refs 7, 8). The transition of the prehnite–pumpellyite to the greenschist facies lies between 300 °C and 350 °C (ref. 9), thus it has been suggested[4,5] that greenschist facies is present not far below the present day surface over much of the Southern Uplands.

The LISPB seismic profile for the Grampian sector shows P-wave velocities similar to the Southern Uplands Seismic Profile (SUSP[1], that is, 6 km s^{-1} at the surface increasing to 6.05 km s^{-1} at 12 km depth[10]. Mainly amphibolite facies sediments (and granite) occur in the northern part and foliated greenschist facies greywackes occur in the south[11]. In New Zealand, the seismic profile for the Otago greenschist terrane shows a velocity of 6 km s^{-1} for the depth range 1–10 km, lying above a velocity of 6.7 km s^{-1} (ref. 12). In Otago the transition from prehnite–pumpellyite facies to greenschist facies is marked by a transition of poorly foliated greywackes to strongly foliated quartzo-feldspathic schists[13]. Individual mica- and chlorite-schists from Vermont, USA, have experimentally determined velocities (at the appropriate pressures) similar to SUSP[14]. We conclude that the SUSP velocities are compatible with the occurrence of foliated greenschist facies metagreywackes at depths 1–5 km below the present surface.

Velocity anisotropism in foliated metamorphic rocks is well known[12,15] and the 15% anisotropy measured at Eskdalemuir (EKA)[1] is very similar to that in slate, chlorite-schist and mica-schist measured experimentally[14,16] at the appropriate pressure. Similar anisotropism is present at the Broughton array (BTN)[1] if the contribution of arrivals from the Midland Valley is ignored. We conclude that the seismic evidence from the BTN and EKA arrays supports the existence of subvertical, NE–SW foliated greenschists at a shallow depth.

Hall *et al.*[1] reinterpreted the Southern Uplands LISPB sector[10] in terms of block-faulting of crystalline crust. We are not competent to quantify a seismic model involving the block-faulting of a thin layer of isotropic greywackes lying above anisotropic greenschists but we point out that the boundaries between the seismic blocks[1] correspond well with existing block faults[5].

The geological arguments of Hall *et al.*[1] are equivocal: the xenoliths could originate from English continental crust subducted below the Southern Uplands[2]; the Midland Valley conglomerates may have come from the upper 11–17 km of the prism (Cockburnland[17]) which has since been stripped off[4].

We conclude that the seismic evidence supports a thick accretionary prism in the Southern Uplands. We predict that a suitably positioned borehole sited in blocks F2 or F3 will penetrate greenschist facies metagreywackes rather than crystalline continental basement.

HALL *ET AL.* REPLY—Oliver and McKerrow accept our conclusions that there are crystalline rocks at shallow depth in the Southern Uplands. Their suggestion that the rocks are greenschist facies metagreywackes, part of an accretionary wedge occupying nearly all the present crustal pile, represents an unlikely possibility rather than a probability more central to all the evidence.

Shots on LISPB[1] and the Otago line[2] are too far apart to provide good control on shallow velocities. Inspection of the original LISPB data from shot 1 suggests that the velocity of Dalradian greenschist metasediments is significantly less than 6 km s^{-1} at 1 km depth (in the fast direction—along the horizontal banding of the 'flat belt'). From this and other field measurements across banding, we estimate that at 1 km depth these rocks would have a mean velocity of ~5.6 km s^{-1} and anisotropy of less than 7%. The Otago data may be modelled similarly.

Laboratory data[3–5] show average values for anisotropy in small cores of schists and associated rocks at pressures corresponding to 3 km depth to be only 7–9%, although higher individual values are found. Less anisotropy would be expected in the field. The 15% anisotropy sought by Oliver and McKerrow is likely to require the rocks to have a 40% content of mica[4] oriented consistently throughout the region.

Thus, Oliver and McKerrow's claim that greenschist facies metagreywacke at 1 km depth would have a mean velocity of 6 km s^{-1} and 15% anisotropy is at the limit of possibility.

Turning to the geological evidence, it is unlikely that a 'regional' metamorphic transition from a greywacke with little or no fabric to a wholly reconstituted mica schist occurs over only 1 km depth, despite the 'dynamic' example near the Alpine Fault[6]. Oliver and McKerrow themselves imply elsewhere[7,8] that the transition in the Southern Uplands takes place over a depth range of 7–12 km.

Oliver and McKerrow imply that the accretionary wedge occupies more or less the whole crust north of the subduction zone indicated on WINCH[9] and with at least 10 km already removed by erosion, the stack must have reached a thickness of 40 km or so, far in excess of present-day examples[10].

Xenoliths from post-Caledonide vents in the Southern Uplands are sufficiently similar to those of the Midland Valley to suggest derivation from a similar crust[11]. It has yet to be established if the English continental crust could supply xenoliths of this type, and whether such crust extends far enough north (interpretation of the Iapetus Suture on WINCH suggests that it does not).

Northward translation[12] of the Southern Uplands is required to account for the missing Ordovician fore-arc basin, and to cover the source of the Silurian conglomerates. We cannot seriously entertain the idea that the substantial thickness of Silurian rocks in the southern Midland Valley came from Cockburnland which, in addition, has to supply sediment to a coeval trench to the south yet is rarely more than 5 km wide[12], and occasionally substantially less[13]. The conglomerates

are unlikely to have come from the top of an accretionary pile because the clasts include acid igneous rock fragments (probably first cycle) and foliated greywacke.

Geomagnetic reversals

RECENTLY Valet *et al.*[1] presented palaeomagnetic data associated with a pair of reverse-to-normal (R–N) polarity transitions from western Crete. The two transition records, differing in age by about 1.2 Myr, were found to possess very similar directional field behaviour in that the corresponding paths of the virtual geomagnetic pole (VGP) were shown to be nearly identical. The authors then noted that an earlier reported N–R VGP path from Crete[2], associated with the transition which closely follows in time the younger of the two R–N reversals, is largely discrepant to the other paths. Given these comparisons, the authors conclude, first, that requirements of the standing field model for transition fields[3] are not satisfied by these data, and second, that the reversal mechanism in the core may be associated with a definite field configuration over some period of time such that successive reversals of the same sense recorded at the same site will be associated with identical VGP paths.

My purpose here is to explore the above argument further. For the authors' assertion to be strictly valid reversals of opposite sense which occur during a time of assumed invariant transitional field characteristics should be observed to possess antipodal VGP paths when recorded at the same site. If, on the other hand, the reversal process is asymmetric such that each transition sense is associated with a different field configuration, then antipodal behaviour probably will not be observed. The question now is: how does the VGP path associated with the N–R transition record[2] compare with the two R–N transition paths[1]?

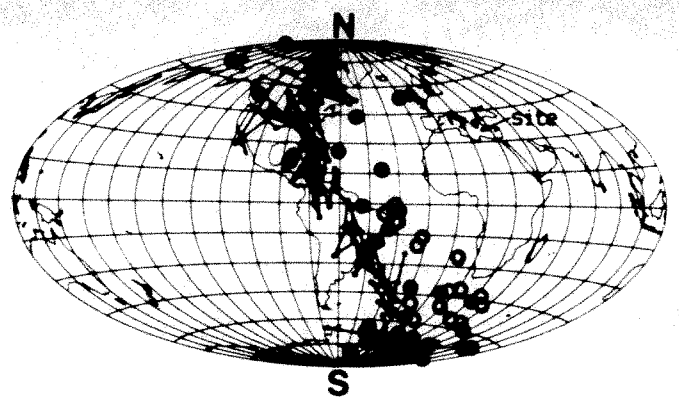

Fig. 1 Paths of the virtual geomagnetic pole associated with three polarity transitions recorded on Crete[1,2]. The drawn path depicts north poles associated with KS06 R–N transition. The solid circles are north poles associated with the older KS02 R–N transition. The open circles are south poles associated with the younger N–R transition (after refs 1, 2).

Figure 1 shows the highly detailed VGP path associated with the younger (KS06) R–N transition[1] along with individual VGPs associated with the older (KS02) R–N transition[1]. Also plotted are the individual south VGPs corresponding to the N–R transition[2]. As can be seen in the figure, all three records contain intermediate VGPs which reside along a relatively narrow path west of the site. Indeed, the longitudinal span of this combined path narrows to less than 45° for near-equatorial poles. Furthermore, an east-to-west migration of intermediate VGPs is a common feature of all three paths, where data exist.

For the R–N north pole transition paths to be found in close proximity to the N–R south pole transition path implies that the north VGP paths of the former transitions are roughly antipodal to the north VGP path of the latter transition. This finding suggests that the harmonic content during all three reversals was quite similar apart from a complete change in sign of the transition field associated with the N–R event. Such a situation is consistent with a reversal process whose time-dependent configurational characteristics are independent of transition sense.

In this regard, the generalized flooding model[4] can successfully accommodate these data through a simulated reversal process which begins and extends from the same localized region in the core for all three polarity transitions from Crete. It is interesting, however, that a pair of recently reported sequential reversals (R–N and N–R) from Kauai, Hawaii[5], have nearly identical north pole transition paths. Such a case cannot be strictly explained by the above arguments, but suggests that major changes in the characteristics of the reversal process in the core can occur abruptly between successive geomagnetic transitions.

VALET AND LAJ REPLY—We have limited our comparison to two reverse-to-normal (R–N) paths from transitions recorded in the same section. Hoffman remarks that a more complete picture can be obtained using antipodal virtual geomagnetic pole (VGP) paths of N–R transitions. Using the south VGPs relative to a N–R transition recorded in a nearby section at Potamida (which we now call KP02), he concludes that the paths of all three transitions are very similar.

The data for this N–R transition, however, although detailed, are not rigorously classifiable as category 'A' because of lack of points in the second half of the transition[1], as remarked by Hoffman himself[2]. A new detailed sampling with very precise stratigraphic control yields a much more detailed and still unpublished VGP path quite similar to the previous published one, although some differences exist in the equatorial VGPs. A comparison between the KS06 transition VGPs and the south VGPs of this new record is shown in Fig. 2. We believe that this figure shows that the R–N paths from Skouloudhiana and the South Pole N–R path from Potamida are not identical (the difference between the two is smaller

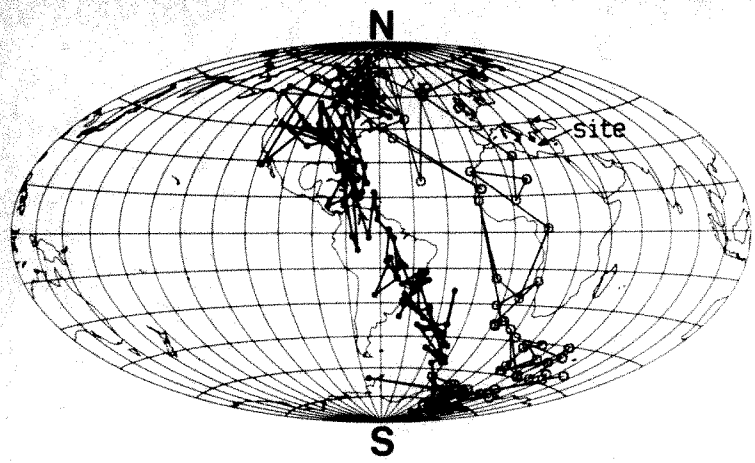

Fig. 2 Paths of virtual geomagnetic poles associated with the KS06 (solid symbols) and KP02 (open symbols) transitions. For KS06 the path depicts north-VGP, for KP02 south VGPs. The two paths appear to be clearly distinct, although an east-to-west migration of intermediate VGPs exists in both of them.

but in our opinion still significant when the old N–R record is used). Moreover, the following remarks can be made.

As pointed out by Hoffman, an east-to-west migration of intermediate VGPs is a common feature of all three paths. In our paper[3], we had erroneously thought that this characteristic was related to properties of the Skouloudhiana section. We now agree with Hoffman that it is related to the reversal's mechanism.

The N–R transition in Potamida lies outside the time interval between the two R–N reversals in Skouloudhiana, so the difference observed in the VGP paths indicates that some differences exist between the transitional field configurations relative to KS02 and KS06 on one side and KP02 on the other. It does not, however, yield any information about the N–R transitions occurring during the time interval between KS02 and KS06. Data about these transitions are thus needed to determine whether the differences observed in the VGPs paths are due to some changes in the reversal mechanism occurring between KS06 and KP02 or whether transitions of opposite sense are always associated with different field configurations.

In Skouloudhiana, unfortunately, the NRM intensity of the sediments at the corresponding stratigraphic horizons is very low, so that measurements are difficult. However, some measurements are now in progress using a cryogenic magnetometer, and we hope to solve this problem.

Factors determining desert dune type

IN their study of aeolian dunes, Wasson and Hyde[1] concluded that sand supply is an important determinant of dune type. Their study was based on the assumption that equivalent sand thickness (EST, defined as the ratio of sand volume within dunes to the area of a dune field) can be used to quantify sand supply and sand availability. Our purpose here is to argue that EST is a measure of dune size and shape, not a measure of sand supply. As a result, the technique of equating EST and sand supply can be shown to lead to incorrect conclusions when tested with subaqueous bedforms.

Sand supply and sand availability are general terms that might be loosely used for at least five quantities: (1) the volume of sand within dunes in a unit area of dune field (equal to EST), (2) the total volume of potentially erodable sand in a unit area of dune field, including sand below the surface that passes through dune troughs, (3) the fraction of a dune field covered by erodible sand, (4) the rate at which sand is supplied to a unit width of dune field from upwind sources, and (5) the rate at which sand accumulates in a dune field (that is, the rate of deposition or erosion, which is equal to the difference between the rates at which sand enters and leaves a unit area of dune field[2]). The first two quantities have units of length, the third is dimensionless, the fourth has units of area/time, and the fifth has units of length/time. In precise usage, the parameters that measure sand abundance or availability [quantities (1)–(3) above] must be distinguished from the parameters that measure rates of sand transport [quantity (4)] or accumulation [quantity (5)].

Wasson and Hyde state that 'Sand supply and EST are often identical but the possibility of sand moving through dunes into areas outside dune fields ... means that EST and sand supply may not be exactly the same for highly mobile dune fields, in areas of high wind energy.' Although no single parameter can quantify all five types of sand 'supply' listed above, the statement quoted seems to imply that a quantity measured in units of length (EST) might somehow describe a sediment-transport-rate quantity if the rate is not too high.

Another problem with using EST to measure sand availability is that EST does not include erodible sand that may occur below the surface that passes through dune troughs—a quantity that may represent the bulk of sand in a dune field. In other words, EST is a measure of available sand only if all available sand in a dune field is incorporated within dunes. This assumption, which forms the basis for Wasson and Hyde's analysis, is unsupported, and it is clearly incorrect in areas where dunes deposit cross-stratified beds, because in such areas of deposition, sand is transferred from dunes to underlying beds[2]. The problem of quantifying sand availability might be eliminated by measuring quantity (3) listed above (the fraction of a dune field covered by erodible sand), rather than measuring EST.

Because EST is independent of fluid medium, it is instructive to test Wasson and Hyde's analytical technique with subaqueous bedforms, about which more is known. From a plot of subaqueous bedforms as a function of EST and current variability (like Wasson and Hyde's Fig. 4) one might incorrectly conclude that sand waves occur where sand is abundant, that upper-regime flat beds occur where sand is scarce, and that ripples occur where sand abundance is intermediate. (In reality, flow strength is a more important determinant of what type of subaqueous bedform is produced.) The point of considering subaqueous bedforms is not to argue that aeolian bedforms behave similarly, but rather to demonstrate that, regardless of fluid medium, a correlation between bedform type and EST does not prove that EST (or sand supply) is a determinant of bedform type. Instead, EST may merely reflect bedform type, with bedform type determined by other parameters.

As a result of their EST-based analysis, Wasson and Hyde conclude that; (1) barchans occur where there is very little sand, (2) transverse dunes occur where sand is abundant, (3) longitudinal dunes occur where there is little sand, and (4) star dunes occur where sand is abundant. Conclusion (1) is undoubtedly correct, but the other three conclusions are suspect. For example, transverse dunes form in some areas with so little sand cover that underlying rocks or sediments are exposed in deeper parts of dune troughs, and the dune height in some such areas is so small that the mean thickness of erodible sand in the dune field is no more than a few metres.

The conclusion that longitudinal dunes occur where there is little sand is unjustified because the EST measurements on which that conclusion is based are incapable of identifying areas with little available sand (because additional sand may underlie dune troughs).

This question about whether longitudinal dunes can occur where sand is abundant has important ramifications to geologists studying aeolian deposits. If longitudinal dunes can occur only where sand is scarce, they should be unable to produce deposits without causing their own destruction or evolution into other kinds of dunes.

1. Wasson, R. J. & Hyde, R. *Nature* **304,** 337–339 (1983).
2. Rubin, D. M. & Hunter, R. E. *Sedimentology* **29,** 121–138 (1982).

WASSON AND HYDE REPLY—The aeolian sand both in dunes and swales is that proportion of the total arenaceous sediment, lying either beneath or upwind of a dune field, that has been made available for deflation and dune construction. It follows that equivalent sand thickness (EST) in a dune field in which all of the aeolian sand lies within the dunes is a good measure of the sand made available for dune construction. In dune fields where a large volume of aeolian sand lies in swales, EST is a minimum estimate of the total volume of aeolian sand in the dune field. We do not claim[1], as Rubin believes we do, that EST equals the total arenaceous sediment body that might be deflated in either conditions different from those that have prevailed during the history of the dune field or at some future time. Observations in a number of dune fields clearly show that not all sandy sediments have been deflated to form dunes. In the Thar, Simpson and Kalahari, for example, large stores of non-aeolian sand lie both beneath and upwind of the dunes[2,3,4].

Examination of pits, wells and bore-logs both by us and by others shows that significant quantities of aeolian sand lie in swales in fields of star and transverse dunes, very little in fields of longitudinal dunes and none in areas of barchans[5]. The inclusion in estimates of EST of this fraction of aeolian sand would therefore enhance the differences between star/transverse and longitudinal/barchan dunes on our Fig. 4.

We concluded that drift potential (DP, a measure of wind strength) does not correlate with dune type but we now go on to suggest that vegetation and sand moisture have always been modulators of sand transport rates in presently arid to semi-arid dunefields (for example, Australia, Thar, Kalahari). In presently hyper-arid dune fields (Namib, Sahara, Rub'al Khali) sand transport has always responded directly to the fluid medium. We also note the possibility that EST has been controlled by a number of meteorological and biological factors that differ both between dune fields and through time. The control of subaqueous bedforms by the fluid medium does not have a simple parallel in subaerial dune fields. For example, there is no equivalent of vegetation in river bedforms, and the density differences between solids and the transporting media in the two cases cautions against a simple comparison of the kind suggested by Rubin. Therefore, a test of our ideas about desert dune fields using subaqueous bedforms is casuistry. Rubin notes that he does not wish to infer that aeolian and subaqueous bedforms behave similarly, making his comparison even more puzzling.

One of Rubin's objections to our conclusions is his observation that transverse dunes form in some areas where swales are not covered by aeolian sand, thereby implying low EST. In our Fig. 4 only 1σ is plotted about the mean of EST for each dune type so, clearly, low values of EST were included in our sample. We do not claim that all values of EST in transverse dune fields are higher than all values of EST in longitudinal dune fields. We have used statistical significance as our criterion of difference. Rubin's citing of a few undocumented and unquantified examples unfortunately follows in a long tradition in aeolian geomorphology. We specifically set out to quantify relationships using all of the best data available to us, so as to avoid the selective use of examples.

It is relatively easy to see how the variable RDP/DP might influence dune type. The role of EST is less clear, and so our use of this variable is best viewed as an aid to discrimination between dune types. If transport rates have always been higher in presently hyper-arid dune fields, by comparison with presently more humid dune fields, then it is possible that EST reflects, among other things, the presence or absence of long-distance sediment transport by wind. Star dunes have the highest values of EST and occur in areas in the Sahara where sand flow converges[5–8]. Simple longitudinal dunes in the Simpson–Strzelecki dune field of Australia have low values of EST and have been derived from sediment sources close by[2]. It is conceivable that EST reflects dune type rather than vice versa. Rubin's comments have highlighted this unresolved problem but we cannot agree with his conclusions.

J. A. MABBUTT COMMENTS—The exchange of views between Wasson and Hyde[1] and Rubin has been useful in clarifying controls over sand availability for dune formation, but in my view does not go far enough in considering how this in turn acts to determine major dune type. This determinant would appear to be the extent of non-dune surface suited to the rapid transmission of saltating sand, relative to the area of sand-trapping dune surface. Where the former is so dominant as to leave the dune accumulations isolated, barchans characteristically develop; where the relationship is such as to allow the continued exposure of downwind-oriented non-dune strips, longitudinal dunes are typical; where, on the other hand, the non-dune floor remains completely buried or revealed only in minor and non-connecting troughs, transverse dunes are found. In many dune fields these relationships occur in sequence downwind towards a basin depression of sand accumulation, and there is a corresponding downwind sequence of dune form. A whole range of circumstances can intervene to determine these relationships locally, including thickness of prior sands available for wind-working into dunes, current aeolian sand supply, the transmissivity of the underlying floor, wind energy and vegetation cover.

Patterns of longitudinal dunes, in which dune and non-dune surfaces are more evenly matched in extent than in the other dune types, are strongly influenced by variations in the nature of this non-dune surface. A recent account of longitudinal dunes in the north-west Simpson Desert[2] shows that the non-dune 'floor' can vary locally between soft unconsolidated sand (partly wind-worked sandy alluvium?), firm surfaces of coarse-textured alluvium, and hard gibber pavements. The dunes that cross these surfaces may accordingly vary between wind-sculpted forms, sand mounds assembled *in situ*, and transgressive dunes. There is strong evidence that differences in sand-transmissivity between the non-dune 'floors' have contributed to differences in spacing and other pattern attributes.

Singular mathematics

n Goodwin

Catastrophe Theory. By V.I. Arnold. Translated by R.K. Thomas. *Springer-Verlag: 1984. Pp.78. Pbk DM 16.80, $8.50.*
Mathematical Models of Morphogenesis. By René Thom. *Ellis Horwood/Halsted: 1983. Pp.305. £25, $59.95.*

"THE nice results of singularity theory are happily not dependent upon the dark mystics of catastrophe theory". Thus V. I. Arnold, a distinguished Russian mathematician, sums up a widely-held professional view of the most extraordinary mathematical development of the century. However, in René Thom's new book, a collection of essays written between 1967 and 1981, Thom goes a long way towards clarifying some of the misunderstandings that lie behind Arnold's judgement, which reflects certain deeply-held prejudices of the scientific community. To put this far-reaching conflict of views into perspective, the remarkable history of catastrophe theory needs to be considered.

Ten years ago, an area of deep and difficult mathematics, involving profound theorems that had aroused the interest of the world's finest mathematicians, suddenly became the topic of newspaper and magazine articles, common-room discussion and party gossip. This resulted from two events: the publication in 1974 of René Thom's first book, *Structural Stability and Morphogenesis*; and E. C. Zeeman's communication to the International Congress of Mathematics in Vancouver in the same year, describing the application of Thom's ideas to a great variety of problems, not only in mechanics and physics but also in biology and the human sciences.

Thom had extended and developed a theory of the mathematician H. Whitney, published in 1955. Whereas classical (i.e. Newtonian) differential calculus considers only smooth, continuous processes, Whitney's theory allowed for a systematic study of the discontinuities, breaks or jumps that can occur in a dynamical process, described by its singularities. Smooth mappings and their singularities are extremely widespread and familiar: flows and wave formation in liquids, meteorological fronts and turbulence, regions of intense illumination due to light (rainbows, curves of bright light at the bottom of swimming pools), the condensation of water vapour, the formation and propagation of defects in crystals, and so on. Following Whitney's basic study, singularity theory developed very rapidly and acted as a focal point for the combination of some of the most abstract areas of mathematics (differential and algebraic geometry and topology, group theory, commutative algebra etc.) with some of the most applied (stability theory, bifurcation theory, geometrical optics etc.)

Thom combined the abstract and the concrete to formulate a comprehensive taxonomy of the singularities that could occur in spaces of four dimensions — three of space and one of time; the world as we know it — suggesting that these singularities are the origins of all natural forms that arise in a sufficiently structured (e.g. polarized) system. Christopher Zeeman located this theory within the broader context of general systems, greatly extending the potential applications of the theory and including the human and social sciences; and he it was who suggested the term "catastrophe theory". The dual offer of a systematic theory describing the genesis of form from Thom, together with Zeeman's examples illustrating its non-linear dynamical applications, suddenly opened a door to an extraordinary world of mathematical modelling. Large numbers of people passed through, but soon many were shouting that they had been offered false goods; that the emperor had no clothes. What did they find in that promised land?

Arnold's clear and often entertaining little book (for which the translator should take some credit) casts a caustically illuminating eye over what he sees as a typically Western marketing phenomenon, summing it up in a quotation from Dorochevich: "I think, my dearest, that all this decadence is nothing more than simply a way to approach tradesmen". His own scientific judgement is severe: "In the majority of serious applications, the singularity is a Whitney cusp [describing basic reversible discontinuities or phase transitions, such as gas condensation and vaporization] and the result was known before the advent of catastrophe theory". This is certainly an over-reaction, for there are thoroughly rigorous applications of the higher-order catastrophes to physical phenomena that depend upon Thom's extension of the Whitney theory, such as the use of the elliptic umbilic to study and *predict* hydrodynamic stagnation points in the six-roll mill experiments of Berry and Macklin. And, in biology, Zeeman has applied catastrophe theory in original and useful ways to morphogenetic processes in embryos, making predictions and stimulating experiments the results of which are consistent with the model. However, Thom distances himself from such applications, insisting that there is a much more profound use of catastrophe theory than the rigorous quantitative analysis that Arnold takes to be the measure of mathematical modelling and good science. What is this vision?

The subtitle of Thom's first book was *An Outline of a General Theory of Models*. Despite its title, this second book is, like the first, more about a general theory of modelling than about actual models. Readers may or may not like this style of theorizing, but once accepted the book can be read for what it is: an inspired and imaginative exposition of both a scientific methodology and a research programme, illustrated in diverse contexts (physics, biology, psychology) by using catastrophe theory to sharpen questions rather than to obtain answers to specific problems. Like a piece of classical theatre, the climax of the book comes in the middle, Chapters 7 and 8, containing Thom's defence of his conception of his theory. With a gesture characteristic of the central image of catastrophe theory, the bifurcation set of the cusp, Thom opens our imaginations with a perceptive discussion of the aims of science and the nature of space-time, magic and geometry, and then brings these perennial themes into sharp focus on a problem for which he offers, not an answer, but a programme of investigation.

The discussion is centred on the struggle to unify action with understanding, the former aiming to resolve local problems while the latter seeks the universal or the global. Thom argues that the great scientific successes (Newtonian gravitation, electromagnetism, quantum mechanics, relativity theory) are non-local theories that describe the magic of action-at-a-distance in terms of strictly controlled local manifestations: for example, Maxwell's equations localize electromagnetism; Einstein rendered gravitation local. Theories that have no "magical" non-local elements, argues Thom, do not introduce new possibilities of action. "Catastrophe theory, anti-magic *par excellence*, pushes the principle of locality to the extreme: this is without doubt why it hardly offers new practical possibilities". Must it not, then, also fail to provide insight or understanding, since it has no global properties? Here Thom offers a research programme the objective of which is to construct the global from the local by a procedure in which the *Urbild* of spatiality, the generative principle of space, is an organizing centre that unfolds, like the big bang model in cosmology or the embryo which develops from the egg. This is clearly congenial to catastrophe theory which is precisely about the unfolding of form from organizing germs in space-time, about those singularities which contain in intensely localized form the potential for generating a specific, extended structure. But a rigorous mathematical theory of such a generative procedure is as yet non-existent.

The absence of an appropriate theory, however, does not stop Thom from exploring implications for research in biology,

linguistics, semiotics and semantics. His cognitive programme is to geometrize thought itself, using the elementary catastrophes as logoi, the algebraico-geometrical structures which stabilize concepts in mental activity space. Semantics is based upon approximate isomorphisms between logoi of material beings and those of the corresponding concepts, and so mind perceives real properties of objects which are the "bearers of meaning". His objective is then "to create a theory of meaning whose nature is such that the act itself of knowing is a consequence of the theory; i.e., when an appearance appears to us as a bearer of meaning, we will know why and to what formal facts to attribute it".

What people have primarily reacted against in Thom's writing is the highly discursive style combined with the sharply-defined analytical tools of abstract mathematics. We are used to having mathematics applied to specific problems, leading to solutions. Thom applies it to perennial philosophical and scientific problems, leading to further questions. Clearly catastrophe theory works in physics, where singularity theory worked before, and it is clear how to apply it following that lead. This is the path of wisdom Arnold recommends and illustrates. No one has yet shown how to apply catastrophe theory to the general problems of morphogenesis, cognition and the new physics in the style of a generative science of form suggested by Thom. Until it is tried, it seems premature to condemn it — but no one should be in any doubt about the difficulty of such a programme. □

Thin-necked upright display posture of the male black-billed capercaillie. The drawing is reproduced from Paul A. Johnsgard's *The Grouse of the World*, published by the University of Nebraska Press in the United States and Croom Helm in Britain. Price is $42.50, £30.

Sense of energy

Ian Smart

Sun Traps. By John Elkington.
Penguin/Viking: 1984. Pp.400.
Pbk £3.95, $6.95.

EMBEDDED in Mr Elkington's chapters, on fossil fuels and nuclear power as well as renewable energy sources, there is a feast of fact, from a photovoltaic hat to the mass of firewood needed to dry a kilogram of ginger. Like many "popular" energy books, this one tries to handle an astonishing range of topics by assembling anecdotes about all of them, larded with numbers and speckled with names. It is described as a "comprehensive survey on solar power and future energy". But honest efforts to follow the thread of argument through the labyrinth are repeatedly foiled: diverted into yet another garden of colourful trivialities, or distracted by dramatic writing in the "little-did-he-know-that" tradition.

None of this prevents Mr Elkington from being informative. Nor, which is more important, does it hide his good sense — although it sometimes overshadows it. He begins by pointing out that technical feasibility is no substitute for — or index to — economic competitiveness. And he ends with a studiedly moderate estimate of the contribution renewable sources will make to world energy supply in any of our lifetimes. His assessment could only have been reinforced by more persistent attention to economics. As it is, its moderation serves to highlight the euphoric exaggeration by so many of the sun, wind and wave enthusiasts from whom he quotes: a habit of hyperbole matching the former excesses of nuclear apostles and inviting a similar fate.

Mr Elkington himself gets the balance about right, by characterizing as only slightly optimistic a Worldwatch Institute projection that the renewable contribution to global energy supply will rise from 16.5% in 1980 to 23.9% in 2000 — with three-quarters of the increase coming from hydroelectricity, geothermal power and fuelwood. He is no less right to insist that solar-based energy, exploited at reasonable cost and applied in appropriate ways, must make a larger contribution to human welfare. Unfortunately, he barely touches on the fundamental problems involved: the political and economic tension between centralized renewable energy systems, using "high" technology, and decentralized networks, seeking social as well as technical simplicity; the need to choose between ecologically incompatible interests (as between nature conservation and biomass development); and the ultimate dilemma of whether energy should be converted to accommodate society's demands, or social preferences adapted to efficient energy conversion. It is a pity he did not sacrifice more of his anecdotal scrapbook to exploring them. For, through these thickets of lore, there shine rays of a judicious realism. □

Ian Smart is an independent adviser on international energy policy affairs, based in London.

Walk in the gardens

George Oster

An Introduction to the Physical Chemistry of Biological Organization.
By A.R. Peacocke.
Clarendon: 1983. Pp.302. £35, $65.

FORMALISMS are seductive sirens, for they seem to unify so many disparate threads and they promise deep insights using only mathematical manipulations. Of these seductresses, surely thermodynamics is the most alluring. One of its foremost practitioners, the late Aharon Katchalsky, once observed wryly that "it is such a marvelous tool: you don't know what you put in, and you don't understand what you get out. But you know it must be right!".

In physics and chemistry, thermodynamics has performed as advertised; however, in biology it has yet to live up to its billing. By now, no one expects living systems to disobey the laws of thermodynamics, but these tenets are crude and vague constraints when applied to such systems, and they provide very little insight into the operation of biological entities. Nonequilibrium thermodynamics, by extending the venue of classical thermostatics into the realm of dynamics, promised to deliver new understanding and unifying concepts which could shed light on the mysteries of biological organization. But has it? Well, that is a matter of dispute, and reasonable scientists can disagree — although on this subject they usually do so with righteous zeal.

Clearly, Professor Peacocke feels that the sirens' song is worth pursuing, for he devotes the first half of his book to the subject of "Thermodynamic Interpretations of Living Systems". This label is a bit misleading, for discussion of living systems is rarely opened. Only in a few pages of these chapters is any application to specific biological problems attempted, and these attempts consist largely of recasting several biochemical models in the language of network thermodynamics. Beyond a certain notational and conceptual simplification — not to be sneezed at, to be sure — it is not clear that any new understanding emerges.

Chapter 1 commences with a discursive and philosophical excursion into the muddy waters of "complexity" and "hierarchies", finally enunciating the "central problem of biology" as (according to H. Pattee): ". . . the origin and operation of

the hierarchical constraints which harness matter to perform coherent functions". Well, it is true that we would like to know how things work, but recasting the problem in social science lingo doesn't enlighten me. Indeed, Professor Peacocke has collected together a virtual thesaurus of quotations which he employs to illustrate and entertain as he leads us in Chapters 2 and 3 through the various formalisms of irreversible thermodynamics developed by the disciples of Prigogine and of Katchalsky. And an unusually clear tour it is, although somewhat sparse in mathematical detail.

Part II of the book is entitled "Kinetic Interpretations of Living Systems". Here there is more contact with specific situations, and less development of formalisms — perhaps because the subject matter is more inherently mathematical. However, the applications are more chemical than biological, and the author's treatment barely ripples the surface of some quite deep mathematical waters. For example, in Chapter 4, "The Kinetics of Biological Organization", he describes various chemical schemes which, when combined with diffusion, can produce spatial concentration patterns. He mentions the best work in this field, notably that of Meinhardt and Murray, but the treatment is mostly descriptive, albeit lucid. It seems to me that Professor Peacocke frequently opted for a philosophical digression rather than a detailed description of how to perform the calculations required to test whether a model can exhibit spatial instabilities. These recipes are admittedly complicated, but their absence points out the major problem with the book: it is too sketchy on detail to serve as a textbook, but too mathematical to provide biologists with an introduction to a number of active research areas in physical chemistry. However, I found the book easy and pleasant reading and the wealth of references to be most useful. Chapter 5, which describes theories of macromolecular evolution, especially that of M. Eigen, is especially clear. The concluding chapter, "The Interpretation of Biological Complexity", is, like the introduction, a collection of philosophical quotations from various authors on how to best tackle the problems of biological organization.

I am finally left with the feeling that I was glad to have read Professor Peacocke's book; but I am not sure what the wider audience for it will be. Biologists will not find that the mathematics leads them to new experiments, and physical chemists will have to consult more detailed treatments to acquire the techniques; but both may find some agreeable perspectives from which to view their work. Perhaps the book should be read for what it is: a philosophical walk through the gardens that Professor Peacocke finds most beautiful. □

Poet in the field

Richard Mabey

The Natural History Prose Writing of John Clare.
Edited by Margaret Grainger.
Clarendon: 1984. Pp.397. £35, $67.

THE STANDING of the agricultural labourer-turned-poet, John Clare (1793–1864), as a nature writer has never been higher. Yet his reputation as a *scientific* naturalist has until now rested on his adding to the Northamptonshire lists 65 first county records for birds and more than 40 for plants. These figures are the more remarkable when you consider that they were worked out retrospectively from his poems, and are backed up by nothing more substantial than the absolute conviction his poetry carries of being based on personal experience. Poets might be inclined towards invention, but not, so Clare mythology insists, one who was also a peasant.

Now, thanks to an impressive and sympathetically edited work of scholarship by Margaret Grainger, we have access to an apparently more objective record of Clare's field observations. Mining the seemingly inexhaustible supply of old notebooks, letters, scribbled envelopes and book jackets in the Clare manuscript collection in Peterborough Museum, Ms Grainger has pieced together the bulk of his natural history prose written between 1820 and 1850. Some is little more than random jottings, but there are also the first notes towards a planned *Natural History of Helpstone* (he had read Gilbert White) which he planned to call *Biographys of Birds & Flowers.*

I said "apparently more objective" above because the first thing that strikes you about this collection is how adept this man, supposedly blessed or imprisoned by an "innocent eye", was at *choosing* how he wrote, and at moving between scientific and vernacular modes of classification and expression. In a detailed letter to the publisher Hessey about Elizabeth Dent's *Flora Domestica,* for instance, he writes:

> *Cardamine* page 74 this is calld lilac with us as well as 'ladysmock' but I never heard it calld cuckoo in my life otherwise then [*sic*] by books — the wood anemone is also calld 'lady smock' by childern what the common people call 'cuckoo' with us is one which is a species of the 'Orchis'. . . .

This upstart and professional tone was not at all what his publishers wanted from their tame ploughboy, and it is no surprise that his proposed *Natural History* never came to fruition.

But his working journal (kept between 1824 and 1828) does survive, and is perhaps the most fascinating part of this book — not so much because of the accuracy and rapt attention of his descriptions, but because, just as in the poems, they are worked without any change of perspective into accounts of his own feelings. The life of the fields and of Clare's imagination are one and the same. He saw himself, crucially, as *part* of nature. On 10 September 1824, he is feeling unwell, and records a sorrowful note on the swallows congregating in the walnut trees and chattering as "if they were telling their young stories of their long journey to cheer & check fears". The next day he is writing an essay on "the sexual system of plants" for his *Natural History,* and reading a review of Goethe in the *London Magazine.* And in the journal's appendix there is an

Mansell Collection

John Clare: *part* of nature.

electric account of a meeting with a "will o whisp":

> it blazd out like a whisp of straw & made a crackling noise like straw burning which soon convinced me of its visit the luminous haloo that spread from it was of a mysterious terrific hue & the enlargd size & whiteness of my own hands frit me the rushes appeard to have grown up as large & tall as walebone whips & the bushes seemd to be climbing the sky. . . .

These extracts are classic Clare, troubled, sensitive, highly literate despite the idiosyncratic grammar. Ms Grainger has done for the prose what John Barrell did some years ago for the poetry, demonstrating that its style and perspective are as much a consequence of Clare being jerked "out of his knowledge" by self-education and the disorientating effects of enclosure, as of the depth of his local roots. And in so doing her book raises questions about whether there is any essential difference between "subjective" and "objective" knowledge, and for that matter between poetic and scientific description. Towards the end of the book is Clare's list of the orchids he knew from Helpston parish (16 species, remarkably). In the precise and affectionate detailing of the places in which each species grew — early marsh orchid was plentiful "on a spot called Parkers Moor near Peasfield-hedge & on Deadmoor near Sheef green . . . but these places are now all under plough" — it is both a haunting evocation of the inner geography of Clare's experience, and the most exact account of locations that any historical botanist could demand. □

Richard Mabey is a writer on countryside matters and landscape history, and is currently working on a biography of Gilbert White.

Ice flow and applied mathematics

Charles F. Raymond

Theoretical Glaciology.
By Kolumban Hutter.
Reidel/MTP Press: 1983. Pp.510.
Dfl. 240, $104, £60.95.

THE modern phase of glaciology opened in the late 1940s when a small contingent of physicists became interested in the motion of glaciers and ice sheets. Typical of physicists, they emphasized a research method which isolates characteristic parts of glacier behaviour to illuminate essential physical relationships, and they initiated a progressive growth in understanding that continues today. In the past few years a group with a strong applied mathematical bent has come upon the scene. These scientists like to state problems in their fullest mathematical generality, simplifying them only to the extent needed to make a solution feasible. They bring a new analytical expertise to glaciology.

Although the physical and the applied mathematical approaches are essential complements to one another, in the current glaciological community there is something of a communication gap between people who identify with one or the other. Kolumban Hutter is identified firmly with the applied mathematical viewpoint and through this book advocates it. However, Hutter also recognizes the communication gap and tries to bridge it. He has succeeded in writing a unique and rich synthesis that will please any glaciologist who makes the effort to delve into it.

In broad plan the book proceeds from a brief development of general concepts of continuum physics (Part I), to their application to specific problems in the flow of glaciers and ice sheets (Part II). Along the way there is a narrowing of complexity in the physics and a step-by-step broadening of complexity in geometry and time dependence of boundary conditions.

Part I (about one quarter of the book) covers balance laws for mass, momentum, energy and entropy, the continuity (or jump) conditions for these quantities at boundaries, and constraints on the form of constitutive relations. These principles provide the rigorous framework for describing realistic mechanical and thermodynamic behaviour of both polar (sub-freezing) and temperate (wet) ice.

Part II deals with ice motion in geometries of increasing complexity, starting with a parallel-sided slab and progressing to three-dimensional problems. In addition, the problem of determining the geometry of the free upper surface under steady or time-varying climate is examined. While these topics have been considered in earlier books and review articles, Hutter's development is dramatically different and more expansive. Although a number of mathematical techniques are employed, perturbation expansions are a recurring theme. These analyses impressively demonstrate how far one can proceed with analytical methods, despite non-linearity of ice creep, a basal sliding law, and coupled mass and heat flow.

In the second part in particular, Hutter writes with clarity and confidence. Each chapter is crafted to stand independently yet fit into the whole. The balance of text and equations enables a reader to follow the thread of the mathematical development without necessarily studying all of the manipulative details.

Theoretical Glaciology does not attempt to provide much information about real glaciers or ice sheets. It also does not cover the physics of glacier sliding or water motion through glaciers, which are topics of great importance and considerable research activity. By itself, then, it is not suitable as a text for a general course in glaciology. However, for a graduate-level theoretical course in glacier dynamics it is excellent, and any glaciologist working in glacier dynamics will find access to the book to be essential. Although it remains to be seen whether *Theoretical Glaciology* will open a new era of glaciological research, it will undoubtedly set a new standard for mathematical analysis of ice flow. □

Charles F. Raymond is Professor of Geophysics at the University of Washington, Seattle.

Taxonomy of vision

David J. Tolhurst

Parallel Processing in the Visual System: The Classification of Retinal Ganglion Cells and its Impact on the Neurobiology of Vision.
By Jonathan Stone.
Plenum: 1983. Pp.438. $55, £42.35.

THE mammalian retina contains several populations of ganglion cells. Each population extracts information about different aspects of the visual world and conveys that information differentially to the brain. The notion of parallel processing of visual information has become so pervasive that anatomists, physiologists and psychophysicists are increasingly tempted to explain any observation in such terms. There is now a large mass of data which needs critical examination, partly to distinguish the real from the spurious and partly to resolve the many discrepancies.

It is disappointing, therefore, that Jonathan Stone has not chosen to provide a straightforward review of that published data. Rather, he uses the literature as a vehicle for expressing his views that the classification of ganglion cells is in itself the primary goal and that the central processing of visual information can be understood only in terms of parallel processing. There is no systematic description of the several populations of ganglion cell, and the references to the literature are often so cryptic that arguments cannot be followed unless the reader has a good knowledge of what has been written on the subject. It is unclear why some observations are discussed at length whilst others are ignored. The book, then, is not an introduction to the subject.

Stone's first objective is to classify ganglion cells. He argues with some merit that the taxa should be based on an assessment of the cells' overall behaviour rather than on one "key" feature of behaviour. However, he does not explain how one should classify a cell when individual aspects of its behaviour seem to conflict. The first climax of the book is the proposal that X and Y cell classes are not at the same taxonomic level as the W cell class. Rather, X and Y cells are subclasses of a single XY class. The questions of why there are two kinds of cell and why their behaviour differs in particular ways is hardly considered.

The notion of parallel processing has certainly had an impact on the neurobiology of vision: there are many papers that mention it. However, Stone does not make clear how visual science would have floundered without the invocation of X, Y and W cells. The central processing of visual information is described very firmly from the contention that there must be parallel processing of the information conveyed by X, Y and W cells. Deviations from the theme are dismissed. For instance, the X/Y/W classification is orthogonal to Hubel and Wiesel's classification of simple and complex cells in the visual cortex. Stone implies that the simple/complex classification must, therefore, be unsatisfactory and concludes: "the question of the organization of the visual cortex to process the activities of different groups of ganglion cells is being successfully pursued without employing the 'simple'/'complex' distinction among cortical cells".

Perhaps Stone's use of quotation marks in describing simple and complex cells reveals the degree of objectivity in his discussion of parallel processing in the visual system. This is a book for the converted. □

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

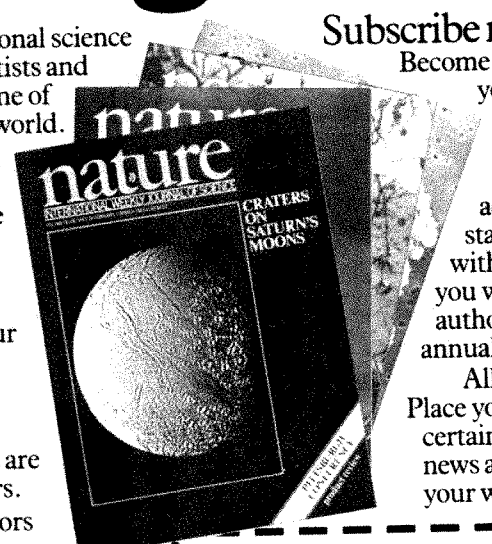
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews—Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews—Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now–and save!

Become a personal subscriber now and you will receive a discount of over 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just $2.12 a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when *you* want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special rate of US$110.

☐ I enclose my personal check for US$110 made payable to Nature. (Note: Institutional checks cannot be accepted at this special rate. The institutional price is US$230.)

☐ Please charge to my credit card account.
Visa/Mastercharge/American Express.

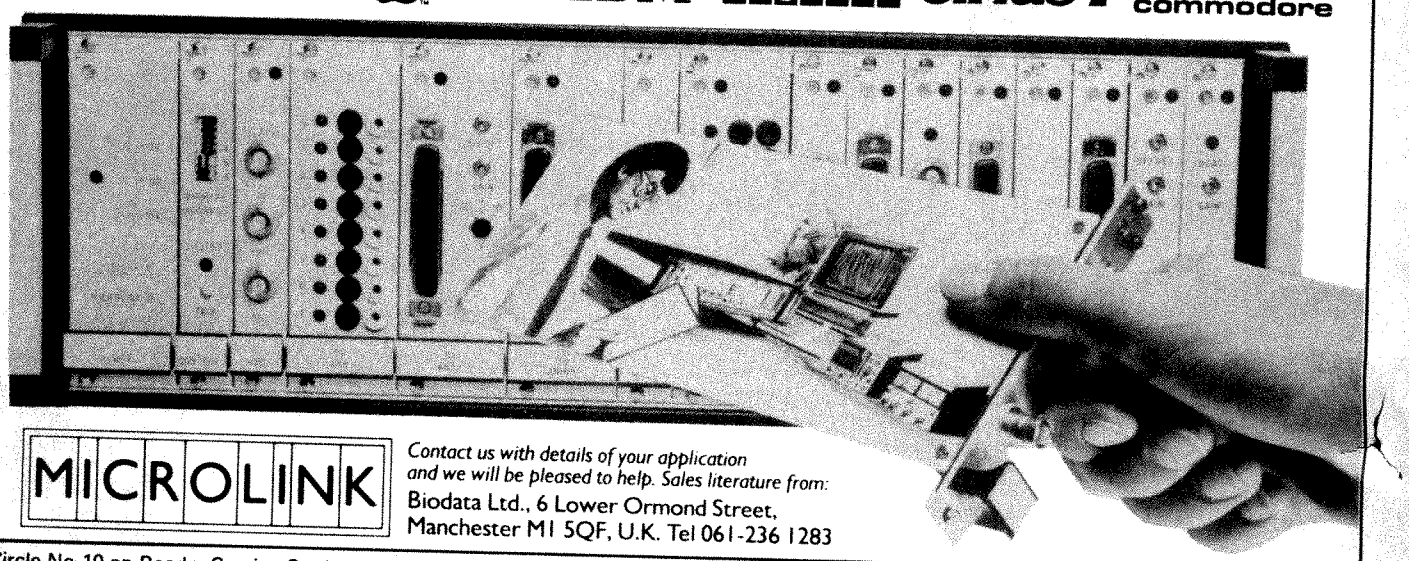
MICROLINK - THE MOST FLEXIBLE COMPUTER INTERFACE



Full modularity MICROLINK is a fully modular laboratory interface designed and constructed to the highest professional standards. MICROLINK uses the IEEE-488 bus, the only real choice for instrumentation systems.

Superlative specification An unsurpassed range of 30 modules including analogue and digital inputs/outputs, timers, counters, RS-232 and thermocouple inputs, allows you to connect almost any instrument to your computer. Data transfer rates of upto 50 Kbytes per sec. are achievable and upto 256 analogue inputs can be accepted.

Full software support Programming manuals are available for most computers with IEEE-488 facilities. Sample programs are provided in BASIC so that you can get your measurement/control system running with minimum delay.

Universal application MICROLINK has been used in environments as varied as North Sea oil production platforms and hospital neurological units, in applications such as: data logging, experimental monitoring and control, environmental monitoring, automatic test and high speed data acquisition.

USE MICROLINK WITH hp apple IBM digital sirius 1 commodore

Women Scientists

The Road to Liberation

Edited by **Derek Richter**
Institute of Neurology, University of London

April 1982 £10.00 313pp ISBN 0 333 32468 4

Anyone should find these glimpses of lives in other cultures intriguing."

"Enlightening for any aspiring scientist who thinks a scientific career is a logical progression from research post to lectureship to chair." **Georgina Ferry, New Scientist**

This book draws together the personal and intellectual biographies of eleven women biomedical scientists. The individual stories are informative, fascinating, and sometimes moving, and cover cultures as diverse as those of India, Iran, USA and the USSR.

Please send orders or requests for further information to Felicity Parker, Product Manager, Scientific and Medical Division, Macmillan Press Ltd., Houndmills, Basingstoke, Hampshire RG21 2XS, UK.

Laboratory apparatus calling

Eleven new products are described this month including a device that "phones home" when your experiment goes wrong.

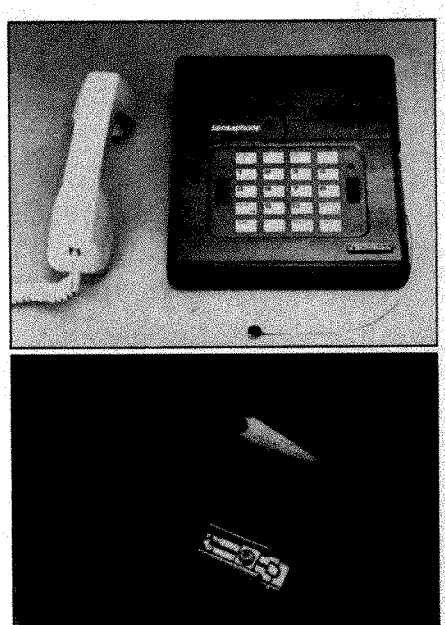
● The Accuspec "second generation" compact gas chromatograph measures only 12½" × 12½" × 15½" high yet offers research-grade performance and a full range of features. The full dual column oven provides a choice of three capillary systems or ⅛" packed column facilities. Automatic cooldown is standard with the temperature programmer. Dual FID, micro-TCD and specific detectors are available.
Circle No. 140 on Reader Service Card.

● The Laser Analytics Division of Spectra-Physics Inc. has developed a cleaved-coupled-cavity Pb-salt diode laser that operates single mode over limited current and temperature ranges. The new device consists of two coupled cavity sections: the front section performs as an emitting laser and the rear section as a modulator. By varying the modulator current, it is possible to tune the emission from the front section thereby obtaining additional precise control of the laser emission characteristics.
Circle No. 141 on Reader Service Card.

● Perkin-Elmer's LC-15B is a new, low-cost, fixed wavelength UV detector for liquid chromatography. At the standard 254-nm wavelength, the maximum noise is $\pm 1 \times 10^{-5}$ absorbancy units while drift is less than 2×10^{-4} absorbance units. Range settings down to around 0.0001 AUFS are included, with response times of 0.2, 0.5 and 1.0. Other features of the LC-15B include a push-button event mark, large digital readout and wide zero baseline adjustment range.
Circle No. 142 on Reader Service Card.

● A high sensitivity auto-ranging electrostatic 'fieldmeter' has recently been developed by John Chubb Instrumentation of Cheltenham. The JCL 101 gives stable measurement of electric fields in the vicinity of 'static' charges on insulating or conducting surfaces.
Circle No. 143 on Reader Service Card.

● Agarose IEF is a highly purified agarose optimized for isoelectric focusing by charge balancing. Gradient drift is reduced to a minimum to give high resolution, stable *p*H gradients and efficient isoelectric focusing. Agarose IEF is produced by Pharmacia.
Circle No. 144 on Reader Service Card.



These notes are based on information provided by the manufacturers. For further details circle the numbers on the Reader Service Card bound inside the journal.

● *Ulex europaeus* agglutinin I (UEA I), a plant lectin recently claimed to be superior to antibody to factor VIII as an endothelial cell marker, is available from Vector Laboratories. UEA I has been shown to identify vascular endothelia in kidney, liver, pancreas, lung, skin, brain, placenta, umbilical cord and cultured cells as well as various tumours of endothelial origin. Unlike anti-factor VIII antibodies, UEA I can be used equally well on snap frozen or paraffin embedded tissues. Several detection systems are available including fluorescein or rhodamine conjugates for fluorescent microscopy, and affinity purified antibodies to UEA I or biotin-labelled UEA I for biotin/avidin-based histochemical techniques.
Circle No. 145 on Reader Service Card.

● The Thermex interface from Columbus Instruments converts an Apple II Plus or Apple IIe computer into an automatic printing 16-channel thermometer. As sensor, it utilizes J, K or T thermocouples. Resolution in the biological temperature range is 0.1 °C. In other temperature ranges accuracy of 0.2% full-scale is achieved by individually calibrated thermocouples. A special calibration program is available to allow the user to calibrate and linearize thermocouple probes in any desired range. Thermex has built in cold junction compensation. Biological probes are available for rectal, intravenous and implantable applications for use in animals. A video monitor displays current temperatures in all channels.
Circle No. 146 on Reader Service Card.

● An ultra-stable stirrer speed in the range 0–1,250 r.p.m. is possible with the ADI 1012 stirrer control unit. Manufactured by Applikon B.V., the controller is specially suited for use in fermentation vessels. With the aid of the ADI 1012's remote speed control input, stirrer speed can be regulated automatically with respect to the culture's oxygen content.
Circle No. 147 on Reader Service Card.

● Antibodies for the detection of oncogene protein products and related antigens — such as the epidermal growth factor receptor — are now available from Oncor. The antibodies are intended for use in immunofluorescence, immunoprecipitation and enzyme-linked assays. The range consists of: AB*myc*.1, AB*ras*.1, AB*src*.1 and AB EGF-R.1. Each antibody is supplied with sufficient product to perform 50 RIP-PAGE assays.
Circle No. 148 on Reader Service Card.

The Omega laboratory monitor (top) and Spectra-Physics new laser

●Constant process monitoring is possible with the new Omega LM-1000 laboratory monitor with voice simulator. It monitors a wide variety of process and laboratory conditions via a standard telephone jack. The LM1000 will monitor conditions such as: room air temperature or ambient sound levels — the LM-1000 can detect a process deviation alarm or presence of excess noise due to vibration. Alert conditions can be checked, for example: limit switch status on computer controlled machinery; status of valve actuated switches; pressure limit switches; and operation of solid state switching devices with control machinery. The LM-1000 automatically reacts to deviations from set conditions by phoning, in sequence, up to four pre-programmed numbers until the message is received.
Circle No. 149 on Reader Service Card.

● A new range of safety coated glass carboys in sizes up to 12 gallons is available from Wheaton Safety Co. The 'second skin' glass carboys are coated with an impact resistant, high tear thermoplastic — transparent, translucent or opaque — providing impact protection to reduce breakage potential and increasing manual handling stability. In the event of container breakage, the coating safely contains dangerous chemicals, and radioactive and biohazardous materials long enough for proper disposal.
Circle No. 150 on Reader Service Card.

Filling jobs by special initiative

Richard Pearson*

The UK Government has boasted of success in encouraging the sunrise industries. Will the manpower be there to support growth?

JOB prospects in science and technology are in a period of rapid change. While new "discoveries" are one major driving force, their application to society's needs and a changing financial context are nowadays equally strong pressures affecting employment. Existing staff need new skills, some have to retrain, while new jobs and areas of employment are always emerging. In the United States, skill shortages in information technology (IT) and electronics have led to severe depletion in the education system of the teachers needed to educate and train future specialists.

In the United Kingdom, cutbacks in the university system in the past 3 years have led many universities to rely on natural wastage to reduce staff numbers. Not surprisingly, those with marketable skills in industry have often been the ones to leave, while the rash of early retirements and freezes on recruitment have led to unbalanced staffing structures and blocked career streams. In an effort to unblock the system, a "new blood" initiative was announced by the Department of Education and Science in late 1982 which enabled the universities to recruit more than 240 new, young, teaching and research staff. There were also funds for a further 70 staff in IT as part of a wider "IT initiative" to increase the supply of graduates coming onto the labour market. Initial evaluations of these two schemes are now available.

Altogether, more than 300 posts were created in the universities and 87 per cent of them had been filled by late 1983. The University Grants Committee (UGC) reported a wide variation in the number and quality of applications for individual posts. The number of applications was as high as 80 for some posts in medicine with many strong candidates, and as low as 4 in engineering. The highest quality was found in applicants in the biological sciences and mathematics, the lowest in engineering. Information technology had the lowest number of applicants per post. Not surprisingly, the posts in engineering and information technology were hardest to fill, with nearly one in five of the information technology posts, and one in three in engineering remaining vacant (see table).

The aim of attracting young staff was largely achieved; more than half the recruits were under 30, and more than 90 per cent under the recommended age limit of 35. Interestingly, one in ten of the information technology recruits was over 36, while three were under 25. In a year dedicated to "Women in Science and Engineering", none of the information technology posts and only one of the engineering posts was filled by a woman, although more were appointed in medicine (6) and the sciences (9).

New posts in UGC new blood and IT initiative

Subject	Posts in 1983	Applications per post	Posts unfilled at 30 Nov.1983
Medicine	43	19.7	5
Engineering	48	15.9	15
Biological sciences	25	32.1	3
Maths/ physical sciences	86	27.3	1
Agricultural/veterinary science	8	13.7	2
Arts/social studies	32	27.5	4
Information technology	70	10.9	13
Total	312	20.8	43

The IT initiative of 1982 also included additional funds for research and student places, as well as for a series of one year postgraduate and post-experience courses to increase the supply of people with IT skills. An initial evaluation of the first year of these courses, sponsored by the Science and Engineering Research Council (SERC), shows them to be making a rapid contribution to meeting recruitment needs despite their newness and a relatively low level of awareness by employers (*Manpower for Information Technology*, A. Gordon and R. Pearson, IMS). SERC is supporting two types of course, "conversion" courses aimed at graduates with no previous experience of information technology and "specialist" courses for information technology graduates.

Although many of the courses, run in both universities and polytechnics, were announced only a few months before they began in October 1982, there was a great deal of interest among first degree graduates — some course organizers received more than 300 applications for 20 or 30 places. Much of this enthusiasm was no doubt prompted by the poor job prospects for graduates without skills in information technology. Although there was a significant number of women applicants, they represented only one in eight students, possibly because many of the successful applicants had first degrees in engineering or physical science, often an essential entry requirement. The students themselves had mixed backgrounds; one in four were from polytechnics, and one in four had non-technical first degrees. Their ages ranged from 21 to 55, half were over 25 and officially classified as "mature" students.

The numbers graduating so far, fewer than 200, were relatively low when compared with the expected 1,000 graduates in 1984. In 1983 there was little awareness among employers of this new source of skilled information technology manpower. Most employers were seeking a broad based intake of first degree graduates and it was rare to find a significant discrete demand for MSc or diploma students in any of the information technology subjects. Some were, however, sought in communications and control engineering. In the case of postgraduates with first degrees in the arts, some employers doubted whether they could learn enough useful computing in one year to be worthwhile, although one major electronics company has recently organized his own three-month courses to turn arts graduates into successful real-time programmers. By the time they graduated, most students had found jobs that used their new skills, with banks and in education as well as in the information technology industry. Starting salaries ranged from £5,000 to more than £12,000 a year, with half in the £7,000-8,000 range, well above the average starting salary for new graduates, which in 1983 was just over £6,000.

The information technology initiative has been successful so far in creating a new supply of skills. Ironically it could be poor information that constrains this supply of information technology skills in the future, with some employers unaware of these new types of graduates, and some course organizers having little interest in ascertaining industry's needs. Women still remain a large untapped source of recruits for the courses and for industry. This always assumes of course that there will be enough teaching staff to run the courses. □

SAMUEL MILTON NABRIT MARCH OF DIMES PROFESSOR

Applications and/or nominations are invited for the Samuel Milton Nabrit March of Dimes Professorship. Candidates with substantial experience in techniques and concepts of molecular genetics and immunogenetics are preferred; although highly qualified investigators in other areas of molecular and cell biology will be considered. It is anticipated that the successful candidates will establish a biotechnology focused research program with emphasis on studies relevant to birth defects in collaboration with faculty colleagues of Atlanta University and Morehouse College. Salary will be commensurate with qualifications and experience.

Submit curriculum vitae, three letters of reference and a statement of current research interests by June 1, 1984 to: Dr Judith Rae Lumb, Department of Biology, Atlanta University, Atlanta, Georgia 30314.

The University is an Equal Opportunity/Affirmative Action Employer.

(NW495)A

KINGSTON POLYTECHNIC FACULTY OF SCIENCE RESEARCH ASSISTANT

The Department of Industrial, Organic and Polymer Chemistry invites applications from suitably qualified candidates to undertake an investigation into the synthesis and properties of thermally and hydrolytically stable crosslinked polymers. The work will include lamination and physical testing of resins prepared.

Candidates should have, or expect to obtain this year, a good honours degree in Chemistry. The successful candidate will be expected to register for a higher degree under the supervision of Dr W E Douglas. The post is for 3 years and involves some teaching duties. Salary within range £5,592 — £6,294 inclusive.

Details and application forms (to be returned by 31st May) from Academic Registry, Dept AO, quoting Ref SC, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366 ext 518.

(1889)A

UNIVERSITY OF CALIFORNIA, IRVINE

FACULTY POSITION IN PHARMACOLOGY

Applications are invited for a tenured or tenure-track faculty position in Pharmacology. We are especially interested in candidates with a background in cardiovascular pharmacology, but qualified candidates in any area of molecular pharmacology will be considered. A Ph.D. in Pharmacology or related area, or an M.D., is required.

Level of appointment and salary will be commensurate with achievement and experience.

Curriculum vitae, references and a summary of research interests should be sent before June 30, 1984, to: Dr. Larry Stein, Chairman, Department of Pharmacology, College of Medicine, University of California, Irvine, California 92717.

The University of California is an Affirmative Action Employer.

(NW491)A

UNIVERSITY OF MANCHESTER MEDICAL SCHOOL

DEPARTMENT OF PHARMACOLOGY

POSTDOCTORAL RESEARCH ASSISTANT REPRODUCTIVE BIOLOGY

Applications are invited for a postdoctoral position funded by the Cancer Research Campaign initially for 1 year with a possible extension to 3 years. The research will investigate and develop treatments which protect the testes from drugs used for the treatment of cancer. Preference will be given to candidates with experience in histology and radioimmunoassay in reproductive biology. Salary on scale Research Fellow 1A £7630—8530 p.a. with superannuation. Starting date not later than October 1, 1984.

Applications and curriculum vitae (2 copies) with the names of two referees should be addressed to DR. I.D. MORRIS, Department of Pharmacology, Medical School, Oxford Road, Manchester M13 9PT, U.K.

(1888)A

Senior Pathologist

Pharmaceutical R&D

Loire Valley

Our client is one of the largest and most successful international pharmaceutical companies with research establishments in several European countries, including the UK and France. The company has its 100-strong European Safety Evaluation Laboratories in France, and it is here that this vacancy has arisen.

The successful candidate will be a senior member of a small team of pathologists supported by well-experienced technical staff. In addition to classical light and electron microscopy, the department is also making increasing use of histochemical and immunocytochemical techniques in the evaluation of animal pathology. Specialist experience in one or other of these fields would be desirable.

Candidates must have either a veterinary or medical qualification, and membership of the Royal College of Pathologists, American Board Certification in Pathology, or equivalent professional recognition. Some experience of laboratory animal pathology would be a distinct advantage, as would a specialist interest in haematology. Written and spoken fluency in English is essential, and the successful candidate, if not French, must be prepared to become proficient in French after a short period.

As one of the senior scientific staff of the Centre, there would be considerable interaction with research colleagues at other international company locations, and attendance at appropriate scientific congresses is encouraged.

A highly competitive starting salary will be negotiated according to qualifications and experience. Other benefits include pension and life assurance schemes, up to 30 days' annual leave, and assistance with international relocation expenses.

Please write in confidence for an application form, or phone if you would like to discuss the appointment further before applying:

Experienced Pharmacologist/ Physiologist

Internationally respected as a leading name in the field of ethical pharmaceuticals, Smith Kline and French Research operates an intensive and innovative research programme. Due to an internal transfer we now have a vacancy for a Pharmacologist/Physiologist within one of our Pharmacology departments.

The successful candidate will be responsible for carrying out and reporting experiments designed to study the pharmacological and electrophysiological actions of drugs and novel compounds on the heart.

We are looking for a PhD, or a candidate with a good honours degree in Pharmacology or Physiology. Of primary importance however is proven experience in cardiac electrophysiological techniques.

We pay competitive salaries and provide a full range of benefits. Please write for an application form or send a detailed c.v. outlining your qualifications and experience, quoting reference number N/965/SB to the Personnel Officer.

SK&F

SMITH KLINE &FRENCH RESEARCH LIMITED
The Frythe, Welwyn, Herts AL6 9AR.

(1952)A

LUND UNIVERSITY, SWEDEN
announces a permanent professorship in THEORETICAL ECOLOGY at the mathemactic-natural sciences faculty

The scientific area includes ecological processes and interactions of general character on the population and ecosystem levels as well as the environmental and evolutionary background of the ecosystem's variation and development. Important parts of the area are formulation of models and hypotheses in correspondence with empirical research.

The appointee is expected to make contribution towards stimulation of the present research programmes and to develop new lines of investigation, in close cooperation with his/her fellow professors in the department. Teaching responsibilities and supervising postgraduate students.

Reference number 5440.

Principles of promotion for a professorship are mentioned in chapter 19, paragraph 13 of the University edict.

The application letter should be addressed to the Swedish Government (Ref nr) but sent to the Registrar, Lund University, PO Box 1703, S-221 01 Lund, Sweden.

Deadline for receipt of materials: May 23. Starting salary: 146,232 – 165,780 Sw. Cr. per annum (before taxes).

The applicant should include the following items in the application:
1. short written summary of his/her scientific and pedagogic activity (1 copy); 2. a witnessed (two names) list of merits and a list of scientific publications (1 copy); 3. a copy of transcripts or testemonials and other papers of recommendation (1 copy); 4. 4 copies of each scientific work – numbered as in the list above (2), which should be separated into 4 packages for review by the selection committee (at the latest within 3 weeks after the deadline).

(W952)A

THE UNIVERSITY OF NEW ENGLAND CHAIR APPOINTMENTS

The University of New England invites applications for the following tenured Chairs:

PHYSIOLOGY – Vacant following the retirement of Professor J. V. Evans. The Department offers courses in Physiology in the Faculties of Science and Rural Science and in Human Bioscience in the Faculty of Arts.

ZOOLOGY – Vacant following the retirement of Professor A. F. O'Farrell. The Department offers a range of courses with emphasis on ecologically-oriented subjects.

Each of the Departments teaches both internal and external students (the latter being required to attend residential schools). Both Departments have active research programmes and supervise postgraduate student research.

In each case the appointee will become Head of Department for an initial period of five years.

The professorial salary is A$48,997 per annum. Academic salaries are at present under review.

Full particulars can be obtained from the Staff Officer, University of New England, Armidale, New South Wales, 2351, Australia, Telephone ISD 61 67 73 2100, with whom applications, which should include the names and addresses of three referees, close on 21st June, 1984.

Informal enquiries may be directed to the Chairman of the Academic Board, Professor I. R. Falconer, Telephone ISD 61 67 73 2938.

(W941)A

Research Opportunity in Marine Physics

The Institute of Oceanographic Sciences has a vacancy at Scientific Officer level with its Marine Physics Group. The work is concerned with ocean circulation and will entail extensive use of computers for the calibration, analysis and presentation of data from recording instruments deployed in the deep ocean.

Candidates should be numerate, preferably with a mathematics and/or physics background. Previous experience with computers is not essential. Applicants should have a degree, HNC/HND or degree standard qualification in an appropriate scientific or engineering subject.

Although there is only one vacancy it may, if suitable candidates are available, be split to provide two part-time posts.

Starting salary will depend on qualifications and experience, but will be in the range of £5,682 pa – £7,765 pa (full-time rates quoted).

Application forms and further details are available from: The Secretary, Institute of Oceanographic Sciences, Brook Road, Wormley, Godalming, Surrey GU8 5UB. Telephone: Wormley (042879) 4141 ext 272. Please quote Reference 84/004/106. Closing date for applications: 18 May 1984.

Opportunities in Pharmaceutical Development

Pathology Division — *Ware, Herts*

Glaxo Group Research is Britain's leading pharmaceutical research organisation, with a distinguished reputation for developing safe and effective medicines. Due to an expanding workload, two positions have arisen in our Pathology Division.

Cytogeneticist

We require a good honours graduate to join our team of Genetic Toxicologists. You will be involved in cytogenetic analysis including metaphase chromosome studies of mammalian cells. You will be expected to assist in the preparation of the specimens for analysis and in the assessment of results. The laboratories are purpose built to the highest standard and equipped with the latest computer technology.

Applications are invited from graduate cytogeneticists with some experience of metaphase analysis.

Reproductive Toxicologist

We require a graduate to be a study supervisor in our Toxicology Department working in the team assessing the safety of new drugs when used in pregnancy.

You will be involved in the implementation of reproductive toxicology studies and ensuring the correct execution of the studies according to GLP requirements.

You will be expected to be fully aware of the status of each study, as it proceeds, by collating and correlating data generated by the department's dedicated computer system.

Candidates should possess a relevant good honours degree together with a sound knowledge of animal anatomy. Experience gained in this field of work would be a distinct advantage.

We offer a competitive salary in the range £6,175-£10,770. Your starting salary will reflect your experience. Other benefits of a highly successful company include participation in Glaxo Group profitability, non-contributory pension scheme, an active sports and social club and, where appropriate, assistance with relocation to this pleasant area of Hertfordshire.

Please write or telephone for an application form, stating which vacancy interests you to: Mr. D. Latter, Personnel Officer, Glaxo Group Research Ltd., Ware, Herts. SG12 0DJ. Tel: Ware (0920) 3993.

Glaxo *Group Research Ltd.*

(1954)A

Rhodes University, Grahamstown, South Africa

Applications are invited from suitably qualified candidates, irrespective of race, colour or creed, for the following post, from 1 January 1985 or as soon as possible thereafter:

Lecturer/Junior Lecturer in Entomology

in the Department of Zoology and Entomology

An interest in biological control, insect ecology, or plan/insect relationships may be a recommendation.

The salary scales are:

Lecturer : R12657 × 780 - 16557 × 936 - 22173 per annum

Junior Lecturer: R9075 × 621 - 10317 × 780 - 14217 per annum

In addition to the above salaries, an allowance of approximately 12% is payable. The initial salary will be determined according to qualifications and experience. Fringe benefits include generous leave privileges, financial assistance towards the University education of children at Rhodes University, and a service bonus subject to regulations. The successful applicant will become a member of the University's pension and medical aid schemes and qualify for a housing subsidy subject to regulations.

Application forms and further particulars may be obtained from The South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE to whom complete applications should be sent by not later than 31 May 1984. (W964)A

Southampton THE UNIVERSITY

SYNTHETIC ORGANIC CHEMIST

Applications are invited for a position of postdoctoral Research Scientist in the Wolfson Unit of Chemical Entomology from 1st October, 1984. The major role would be synthesis of insect behaviour modifying chemicals for use in research programmes leading to new and improved methods of insect control. The Unit is a self-funding consultancy comprising both biologists and chemists working in close cooperation with government and industrial research establishments towards the development of novel pest control strategies. Salary, which will depend upon age and qualifications, will be a minimum of £7,190 per annum (under review). Applications, together with a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Professor R. Baker, Department of Chemistry, The University, Southampton SO9 5NH. (1922)A

Molecular Biologist SC/L2/84/1

ILRAD wishes to recruit a senior scientist to lead its molecular biology programme in theileriosis, trypanosomiasis and bovine lymphocyte antigens. The research group includes 3-4 post-doctoral fellows with senior technical support. ILRAD has a mandate to devise improved control measures for animal diseases and the molecular biology programme plays an important role in the multidisciplinary effort. ILRAD is fully funded by an international group of donor agencies and is equipped to the highest standards.

Current research topics include genetic mechanisms controlling antigenic variation in salivarian trypanosomes, identification of gene sequences which identify species, sub-species and serodemes of trypanosomes, identification of genes coding for protective antigens of trypanosoma and theileria parasites, and analysis of genetic changes in host and parasite associated with lymphocyte proliferation induced by parasitic infection.

Candidates should have a good research record in molecular biology, a minimum of 7 years research experience since obtaining PhD, and proven ability to head a research group.

This position is an international staff position and salary will be paid in US dollars. Initial salary level will be determined by qualification and experience. Moving, housing, commutation and education allowances are paid, and there are medical and retirement benefits. Applications should include a current curriculum vitae and the names and addresses of three referees. Applications, citing the reference number should be sent by 30th June 1984 to:

Chief Personnel Officer,
I.L.R.A.D.
PO Box 30709
NAIROBI
Kenya

(W954)A

UNIVERSITY OF WAIKATO
New Zealand
APPOINTMENTS IN PHYSICS

Applications are invited for a junior lectureship and a lectureship within the Department of Physics. The appointment to the junior lectureship will be for not more than four years.

The successful applicant for the junior lectureship should have either an MSc in physics or a BE in electrical or electronic engineering. The appointee should have basic interests in micro-processors and semi-conductor devices.

The appointee to the lectureship should have a PhD in physics in an electronics area, and would be responsible for the teaching of electronics and associated supervision of MSc students.

The present research interests of the Department of Physics include: Plasma Physics, Theoretical Physics, Solid State Physics, Biophysics and Electronic Instrumentation.

The appointments will be made at an appropriate step on the scale for junior lecturers, which is NZ$16,123 — NZ$18,732 per annum and for lecturers NZ$21,660 — NZ$25,684 per annum.

All enquiries, including details of the prescribed method of application and conditions of appointment, should be addressed to the Registrar, University of Waikato, Private Bag, Hamilton, New Zealand, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close with the Registrar on 31 May 1984. (W960)A

MASSEY UNIVERSITY
Palmerston North,
New Zealand
FERTILIZER AND LIME RESEARCH CENTRE

Applications are invited for the position of

SENIOR RESEARCH OFFICER

in the Fertilizer and Lime Research Centre which is based in the Department of Soil Science. The Centre was established in January 1983 and undertakes research on several aspects of fertilizers, including the development and evaluation of new and improved fertilizer materials and the efficiency of fertilizer use.

The successful applicant will be required to undertake and coordinate research in areas relevant to the interests of the Centre. Some assistance with research administration will be required.

Applicants must have appropriate post-graduate qualifications and at least five years experience in soil fertility-related research. A good publication record and some experience and an interest in research coordination and administration would be desirable.

An appointment at a salary of up to NZ$30,127 per annum is possible depending on qualifications and experience and will be for 3 years in the first instance.

Further details of the position and of the University, together with conditions of appointment, may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University with whom applications close on 30 May 1984. (W959)A

vrije universiteit
amsterdam

The **Subfaculty of Chemistry, Department of Pharmacochemistry** has a vacancy for a

full professor in (molecular) toxicology (male/female)

The department takes care of teaching in pharmacochemistry and is involved in the program for "environmental chemistry". The research program mainly concerns neutrotransmitters. For both the teaching and the research program in pharmacochemistry the subjects are treated in an integrated way, in which chemicals (synthesis, physical-chemistry) and biological (pharmacology, pharmacokinetics, metabolism, toxicology) aspects are involved: for the biological investigations approaches on the molecular level are followed. Additionally the study of quantitative structure-activity relationships is part of the program.

The applicant should have a broad experience in the field of pharmacology, especially of toxicology. He should be able to contribute to the teaching program of the department and to stimulate the development of the research program on molecular toxicology.
He should be willing and able to take part in the administrative tasks of the department and the subfaculty.

The salary will be between Hfl.76.100,- and Hfl. 108.100,-- per annum (excl. 7,5% holiday allowance). Candidates should be prepared to identify with the Christian character of the Free University.

Those requiring further particulars and those wanting to draw attention to suitable candidates are asked to contact the chairman of the nomination committee, prof.dr. H. Timmerman (Department of Pharmacochemistry of the Free University, De Boelelaan 1083, 1081 HV Amsterdam, telephone 020-548 57 26).

Written applications, including a curriculum vitae and a list of publications should reach the Free University within a month after the date of appearance of this advertisement. (Personnel Department, P.O. Box 7161, 1007 MC Amsterdam, The Netherlands). Please quote reference number 610-0584.

VU

UNIVERSITY OF LIVERPOOL

'NEW BLOOD' LECTURESHIP IN PHARMACOLOGY AND THERAPEUTICS

Applications are invited for the post of Lecturer in the Department of Pharmacology and Therapeutics, established under the UGC 'New Blood' initiative and tenable from 1st October 1984. Candidates should normally be aged 35 or under on appointment. Persons holding permanent university appointments in the UK, of whatever kind, are ineligible for appointment to this post. 'New Blood' appointments will be primarily for research.

Candidates should have a special interest in immunopharmacology, and would work closely with established biochemical and clinical pharmacology groups in the Department on problems of drug toxicity.

The initial Salary will be at an appropriate point within a specified range on the Lecturer scale (£7,190 — £14,125 per annum).

Applications, together with the names of three referees should be received not later than 31 May 1984, by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/296/N.

(1875)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF MEDICINE

POSTDOCTORAL RESEARCH ASSISTANT

required for up to 3 years to work with Dr Gregory Gregoriadis on a project supported by the MRC on the use of liposomes as immunological adjuvants in vaccines. Strong background in immunology essential/ experience of liposome technology an advantage.

Salary on Research Range 1A. Application by full curriculum vitae, quoting the names and addresses of two referees. Reference RA/GG.

TECHNICIAN

also required to assist on project. Candidates must hold relevant technical/academic qualifications and have at least two years working experience. Familiarity with immunological techniques an advantage.

Salary on scale £5,491 — £7,098 plus £1,042 London Allowance. Application forms available. Reference T/MU.

Job decriptions for both posts available from the School Office, RFHSM, Rowland Hill Street, London NW3 2PF to which application as above should be submitted by 18 May 1984. Please quote appropriate reference.

(1894)A

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Scientist

Crop Research Division
Lincoln
New Zealand

A geneticist/plant breeder is required in an expanding plant genetics group supporting the established plant breeding programme at Crop Research Division, Lincoln.

Experience and knowledge of plant reproductive biology and genetics is required. Particular expertise in interspecific and/or intergeneric hybridisation, embryo culture, tissue culture and incompatibility in crop plants, especially cereals would be desirable. An applicant with an appreciation of the utility of these techniques to plant breeding programmes could take a leadership role.

An appropriate degree plus substantial research experience essential.

Salary up to NZ$35,731 would be determined according to qualifications and experience.

Further information, application forms, etc, may be obtained from the Migration Branch, New Zealand High Commission, New Zealand House, Haymarket, London SW1Y 4TQ. Applicants should quote reference number Imm 2/ 335/ 54 and forward applications accompanied by a résumé to:

The Migration Branch,
New Zealand High Commission,
New Zealand House, Haymarket,
London SW1Y 4TQ.

Closing date for applications June 15th, 1984.

(W949)A

Experienced Synthetic Organic Chemist

As a leader in the international pharmaceutical field, Smith Kline & French Research Limited has maintained an impressive record of growth, based on a commitment to research and development. Within our Synthetic and Isotope Chemistry Department, we now have an opportunity for an experienced Chemist to fill a senior position which has become vacant through internal transfer.

Applicants should possess a PhD degree in Chemistry with a broad knowledge, including practical experience, of many fields of synthetic organic chemistry. They must also have had a minimum of three years post doctoral experience in industry or academia with a proven track record of creativity and innovation to their credit.

Reporting to the Head of Department the successful candidate will be responsible for leading a team of graduate organic chemists engaged in all aspects of devising new synthetic procedures to medicinally active compounds.

We pay competitive salaries and offer a full range of benefits, which include free BUPA, free life assurance and flexible working hours.

Please forward a detailed CV outlining qualifications and experience, or contact the Personnel Officer for an application form, quoting reference number N/964/SB

SK&F

SMITH KLINE &FRENCH RESEARCH LIMITED
The Frythe, Welwyn, Herts AL6 9AR. (1887)A

Harpenden Laboratory, Herts
Ministry of Agriculture, Fisheries and Food

Mass Spectroscopist (Organic)

...to work on problems associated with pest control and environmental pollution by identifying pesticide residues and other low level contaminants in plant, animal and other substrates using gc-ms, lc-ms, EI/CI, FAB, positive/negative ion-ms and other relevant techniques.

Candidates should have a good degree (or equivalent) in chemistry, biochemistry or other relevant subject. Experience in the techniques used and an interest or experience in computer techniques and/or electronics will be an advantage.

Appointment as Scientific Officer £5680 – £7765 with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 24 May 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

(1951)A **Scientific Civil Service**

ASSISTANT/ ASSOCIATE PROFESSOR
(tenure track)
DEPARTMENT OF MEDICINE
STANFORD

The Division of Oncology will be appointing a laboratory based medical oncologist at Stanford. We are searching for an individual with independent research capability and a record of productivity, preferably in the areas of molecular biology as it relates to viral oncology, immunology, genetics or chemotherapy of neoplasia. In addition, this individual will be expected to participate in teaching programs and patient care in medical oncology.

Send résumé, including bibliography and summary of research goals, to: Dr Ronald Levy, Chairman, Search Committee, Division of Oncology, Stanford University School of Medicine, Room SO25, Stanford, California 94305. Stanford is an Equal Opportunity Employer and welcomes nominations of women and minority group members and applications from them. (NW504)A

Southampton THE UNIVERSITY

NEW BLOOD LECTURESHIP ECONOMIC GEOLOGY

Applications are invited for the post of Lecturer in Economic Geology with particular emphasis on the geochemistry of fluid-rock interactions.

Salary scale: £7,190 × £450 (15) – £14,125 per annum (under review). The initial salary will depend on qualifications and experience.

Further particulars may be obtained from Mr D. A. S. Copland, The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than 25 May 1984, quoting reference no: 2039/N. (1890)A

POST DOCTORAL POSITIONS

Two positions available immediately for PhD graduates interested in cellular and molecular aspects of early mammalian development, introduction of exogenous genetic material into mouse embryos and/or the relationship between embryonic and tumour cells. Bankground in molecular biology, cell culture or developmental biology required. Salary $20,000 per annum.

Positions tenable at Brock University till July, 1985, and then at the new Mount Sinai Research Institute, associated with the University of Toronto. Apply to Dr J Rossant, Dept of Biological Sciences, Brock University, St Catharines, Ontario, Canada L2S 3A1. (NW502)A

The Queen's University of Belfast
NEW LECTURESHIPS

Applications are invited from persons under the age of 35 years for the following new lectureships tenable from 1 October 1984.

INORGANIC CHEMISTRY

Applications are particularly welcome from candidates with interests in the early transition elements, high oxidation state transition metal chemistry, or organometallic chemistry. However, well qualified candidates with other fields of interest are encouraged to apply. Closing date: 15 June 1984.

THEORETICAL ATOMIC PHYSICS OR ASTROPHYSICS

This post is in the Department of Applied Mathematics and Theoretical Physics. Preference will be given to candidates having experience and a strong research interest in theoretical atomic and molecular physics and/or astrophysical plasmas. Closing date: 31 May 1984.

Salary scale for both posts is £7,191 – £14,127 per annum with contributory pension rights under USS, initial placing on scale depending on age, qualifications and experience.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. Closing date: 15 June 1984. (Please quote ref. 84/N). (1916)A

STANFORD UNIVERSITY
seeks candidates for a newly endowed Chair:

The Henry S. Kaplan Professorship in Cancer Biology at the School of Medicine

We wish to identify a distinguished senior scientist who has demonstrated outstanding scholarship in areas related to cancer biology. The appointee would be expected to assume the Directorship of the Cancer Biology Research Laboratory and its associated research training activities.

Please send nominations and information relevant to the applicant's qualifications to the Staff Assistant for the Search Committee, Ms Marian Knox, Dean's Office, Room M-119, Stanford University Medical Center, Stanford, CA 94305. Stanford University is an Equal Opportunity Employer and welcomes nominations of women and minority group members and applications from them. (NW505)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH
DIVISION OF IMMUNOLOGY

Applications are invited for a postdoctoral position in the Division of Immunology to work with Dr B. A. Askonas. The appointment will be for one year, from 1st August 1984, to work on aspects of cell mediated immunity to influenza virus in a mouse model system. Experience in t-cell cloning and tissue culture of lymphoid cells is essential.

The salary will be in the range £8,530 – £10,250 per annum plus £1,186 London allowance.

Applications should include a curriculum vitae and the names of two referees and should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 24th May 1984 quoting ref: IMM/9/P. (1904)A

Southampton THE UNIVERSITY

DEPARTMENT OF MICROBIOLOGY
Applications are invited for a NEW BLOOD LECTURESHIP IN MOLELCULAR GENETICS

Candidates should have a PhD and post-graduate experience in a relevant field of molecular biology. Salary scale: £7,190 × £450 (15) – £14,125 per annum (under review). The initial salary will depend on qualifications and experience. Further particulars may be obtained from D. A. S. Copland, The University, Southampton, SO9 5NH to whom applications (7 copies from United Kingdom applicants) should be sent not later than 30 May, 1984, quoting reference number 2041. (1896)A

UNIVERSITY OF CAMBRIDGE
'NEW BLOOD' LECTURERSHIP IN BIOTECHNOLOGY

Applications are invited for a University Lectureship or University Assistant Lectureship in Biotechnology to commence on 1 October 1984. Candidates should be graduates in chemistry, biochemistry, biophysics or a relevant subject with previous experience in electrochemistry. The person appointed will be expected to contribute to the development of teaching strategies and to complement the active research programme in biosensors/bioelectronics being pursued in the newly established Biotechnology Centre. Industrial experience will be welcome.

Further information about the duties and conditions of appointment may be obtained from the Director of Biotechnology, The Biotechnology Centre, Downing Street, Cambridge CB2 3EF, to whom applications, including a Curriculum Vitae, list of publications, and the names of three referees, should be sent so as to reach him not later than 18 May 1984. (1917)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PHYSIOLOGY

LECTURER

Applications are invited for the above post available from 1 October 1984.

Qualifications in the field of neurophysiology with research interests related to visceral sensory mechanisms are required.

Salary on the academic scale for Lecturers (£7,190 – £14,125) (under review) according age, qualifications and experience.

Informal enquiries may be made to Professor B R Jewell (tel Leeds 431751 ext 7267).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT quoting reference no. 104/11/D. Closing date for applications 21st May 1984. (1910)A

The Queen's University of Belfast
NEW LECTURESHIP IN MOLECULAR BIOLOGY (NON-CLINICAL)
Department of Medical Genetics

Applications preferably from candidates under 35 years of age are invited for a lectureship (non-clinical) in the Department of Medical Genetics tenable from 1 October 1984 or such other date as may be arranged. Applicants should preferably possess a PhD degree or equivalent, and must have experience in recombinant DNA techniques. The lecturer will be expected to help the department expand its interest in the application of molecular biological techniques to human disease and clinical genetics. Initial placing, which will depend on age, qualifications and experience, will be made on the scale for lecturers: £7,191 – £14,127 with contributory pension rights under USS.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. Closing date: 31 May 1984. (Please quote Ref. 84/N). (1914)A

CSIRO

Research Fellow

$A24,344 – $A35,806
Division of Atmospheric Research
Aspendale VIC
Australia

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Atmospheric Research is a member of the Institute of Physical Sciences.

Field: Atmospheric Clouds and Radiation.

General: The Division of Atmospheric Research maintains broadly-based research programs in dynamical meteorology, boundary layer physics, climatology, radiation, cloud physics and atmospheric chemistry. Total staff numbers approximate 130.

The Division's Clouds and Radiation Group is concerned with the meteorological and climatic consequences of the interaction of atmospheric radiation with clouds, aerosols and trace gases, the physics of cloud evolution, including the investigation of natural rainforming processes, the remote sensing of atmospheric and surface parameters by lidar, satellite and airborne radiometric techniques. Recently the group has acquired a comprehensive system for real-time acquisition and interactive handling of high resolution meteorological satellite data (CSIDA).

Duties: As a member of the Clouds and Radiation Group, the appointee wil have considerable freedom to develop and undertake research within the general field. There is also a requirement to strengthen the theoretical background to the Group's present activities and, specifically, to collaborate in research concerned with interpretation of satellite radiances and with investigation of those radiative processes that are affected by the behaviour of clouds, aerosols and by changes in atmospheric trace gases.

Qualifications: A PhD degree or equivalent qualifications with emphasis on theoretical physics and some training in applied mathematics plus proven research ability. Experience in general meteorology and, in particular, the theory of radiative transfer would be an advantage.

Tenure: Indefinite with Australian Government superannuation benefits available.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No A1824, should be directed to:

The Chief,
CSIRO Division of Atmospheric Research
Private Bag No 1
Mordialloc VIC 3195
Australia.

By June 8, 1984.

CSIRO is an equal opportunity employer. (W942)A

of higher education

CONNAH'S QUAY, DEESIDE, CLWYD

BIOTECHNOLOGY RESEARCH POST

(up to £13,443 p.a.)

The Institute's research programme already includes a substantial amount of work on immunoassays and on monoclonal antibodies. It now wishes to increase its involvement in biotechnology especially in view of its support to Newtech, Clwyd's new Industrial Innovation Centre.

The person appointed will join the Academic Research Staff, will be required to undertake and initiate applied research, and to advise local industry. Particular areas of interest are in cloning, immunoassays or cell biology. Applicants should be professional researchers of high academic ability, and should be willing to apply their work to industrial objectives. Salary is between £8,937 to £13,443 pa depending on qualifications and experience. For further details and application forms write to:

The Registrar, The North East Wales Institute, Connah's Quay, Deeside, Clwyd. Tel: Deeside 817531 ext 254. Closing date for receipt of applications: 15th May, 1984. (1878)A

Statistician

c.£13,000 inc. (under review)

Glaxo Pharmaceuticals, one of the fastest growing companies in the UK, markets a highly successful range of leading pharmaceutical products.

We are seeking to appoint a statistician to advise on the statistical aspects of Clinical Trials protocols.

This work will involve an input into the design of protocols, record forms and computer entry screens to ensure that the data can be handled efficiently.

You will be required to analyse clinical data using appropriate methods and computer techniques.

In order to fulfil these responsibilities you will need to liaise with Management Services Division as well as members of Clinical Research Division and other Medical staff.

A strong positive personality is required and you should have considerable experience of the statistical aspects of clinical trial design together with the ability to gain the confidence of Senior Medical Personnel and to co-operate with them.

Attractive conditions of employment include Company bonus scheme, non-contributory pension scheme and other excellent benefits.

Please call for an application form to Mr. M. E. Bates, Senior Personnel Officer,

Glaxo Pharmaceuticals LIMITED
GREENFORD ROAD, GREENFORD, MIDDX. TEL: 01-422 3434, *quoting ref MEB/733.* (1953)A

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMICAL ENGINEERING AND CHEMICAL TECHNOLOGY

POSTDOCTORAL RESEARCH ASSISTANT AND RESEARCH ASSISTANT IN BIOTECHNOLOGY

Applications are invited for two posts to assist in a growing programme of research into the production of fuels and chemicals by fermentation. The work is supported by The Royal Society.

Candidates for the postdoctoral post may be qualified in biochemical engineering or applied microbiology and should have experience and interests relevant to the work of the group which presently includes anaerobic digestion, immobilised cell systems and coupled fermentation and novel separation processes. Initial salary according to age and experience in range £7190-£11615 plus £1186 London Allowance.

Candidates for the post of research assistant should be graduates, preferably in chemical engineering, and have some experience of work in a biochemical or microbiological laboratory. The successful candidate will assist in work on mixing, modelling and evaluation of anaerobic fermentations and will also be required to provide general technical assistance in the biotechnology laboratory. Salary in range £6310-£8530 plus London Allowance according to age and experience.

Applications, naming two referees, should be addressed to Dr D L Pyle, Department of Chemical Engineering and Chemical Technology, Imperial College, London SW7 2BY, to arrive as soon as possible. Informal enquiries also welcome (01-589 5111 ext 1909).

(1949)A

SOUTH MANCHESTER HEALTH AUTHORITY CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE PATERSON LABORATORIES

A vacancy exists at postdoctoral level within a group devoted to the study of the epithelial cells of a variety of tissue. The interests of the group centre on the cellular organisation of proliferation in a wide range of surface epithelia (skin, oral mucosa and gastrointestinal tract), the mechanisms involved in the control of cell proliferation and differentiation and the malfunction of these controls that result in cancer and other proliferative disorders. We wish to bring new scientific interests into the group to add to the wide-ranging approaches that are currently used, and would be particularly interested in someone who could bring experience of monoclonal antibodies or molecular biology techniques or who would be interested in learning these techniques while working in the group. The successful candidate would be able to develop his own area of study within the overall framework and under the general guidance of Dr C S Potten, the group leader. Potential projects could include the identification of early differentiation events in epithelial cell lineages; characterisation of stem cells and clonogenic cells in epithelial tissues and their relationship to carcinogen target cells.

The work is supported by grants from the Cancer Research Campaign and the position would be tenable for three years with the possibility of renewal.

Applications should be made to Dr C S Potten, The Paterson Laboratories, Christie Hospital and Holt Radium Institute, Wilmslow Road, Manchester M20 9BX and include a curriculum vitae, the names of two academic referees and outline of interests in connection with the work outlined above. (1931)A

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST. THOMAS'S HOSPITALS

POST-DOCTORAL RESEARCH ASSISTANT

required for one year to work on cell-mediated immune mechanisms in rheumatoid arthritis. Experience in cloning and hybridoma techniques would be desirable but not essential. This post is funded to 30th June 1985. Salary on the scale of £7,190-£8,530 plus £1,186 London Allowance and superannuation depending on age and experience. For further details 'phone Professor G S Panayi (01-407 7600 Ext 3269). Applications to the Secretary, United Medical and Dental Schools, Guy's Hospital Medical School, London Bridge, London SE1 9RT, quoting Ref DM6.

ROYAL MELBOURNE INSTITUTE OF TECHNOLOGY LIMITED

SENIOR LECTURER (INSTRUMENT SCIENCE)

DEPARTMENT OF APPLIED PHYSICS

REF. NO. 121/06/AN

Applicants are called for the above position. The successful applicant will be responsible for providing leadership to the Instrument Science Group, undertake a variety of teaching duties, and be expected to participate in the overall research and development program of the department.

It is expected that the successful applicant will hold a Ph.D., have extensive experience in tertiary teaching, and have an established research and/or development record associated with instrument science and microprocessor application.

Salary within the range $A31,390 — $A36,585 p.a. (under review).

LECTURER (OPTICS)

DEPARTMENT OF APPLIED PHYSICS

REF. NO. 121/09/AN

The Department is seeking an energetic applicant who will join the Optics group in the above position. The successful applicant will be expected to participate in undergraduate and postgraduate teaching programs and contribute to the research activities of the Optics group within the overall departmental research and development program.

It is anticipated that the successful applicant will hold a Ph.D. in an appropriate field and have demonstrated a research capability and commitment to the field of optics. Tertiary teaching experience would be an advantage.

Salary within the range $A23,394-$A30,734 p.a. (under review).

Position descriptions should be obtained from Staff Branch — (03) 341 2337. Applications quoting appropriate Ref. No. to the Staff Officer, RMIT, GPO Box 2476V, Melbourne, 3001, Victoria, Australia by 27 July 1984.

(W940)A

BIO-COM

BIO-COM (U.K.) LIMITED

Bio-Com seeks for international research associates young independent and ambitious scientist with strong friendly personality, interested in both fundamental and development research. Training: immunology, genetic engineering, peptide-nucleic acid characterization. Initially based at Paris Institution, hence, conversational French essential. Willing to travel/relocate UK/USA. Starting salary £9,000 — £12,000.

Send cv, photograph and manuscript letter to the Director of Research, Bio-Com (UK) Ltd, 34 Floral Street, London WC2E 9DJ.

(W945)A

WELLCOME BIOTECHNOLOGY LIMITED, FMD DIVISION, PIRBRIGHT

SENIOR LABORATORY TECHNICIAN

A vacancy has arisen for a Senior Laboratory Technician to join our Research Team in the Foot and Mouth Disease Virus Section at Pirbright. This Section is part of our Department of Virology R&D at Beckenham and there is considerable interaction with other Biological Research Departments as well as collaboration with external organisations.

Applicants should be highly motivated, educated to degree or HTEC level and have the practical experience to provide full technical expertise required to general full length DNA clones of Foot and Mouth Disease Virus RNA. To obtain infectious virus from such clones and to perform site directed mutagenesis.

The post will attract a competitive salary and excellent benefits including 5 weeks holiday, life assurance, sick pay and pension scheme.

Please write with full details to: Mr. K. Tollett, Wellcome Biotechnology Limited, FMD Division, Ash Road, Pirbright, Woking, Surrey GU24 0NQ.

(1905)A

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

PROFESSORSHIP

DEPARTMENT OF CHEMISTRY

Applicants should have a sustained record of recognised international excellence in their specialist area. The successful candidate will be expected to teach and conduct research in either analytical or physical chemistry. Applicants with lesser experience may be considered for a post at a lower level.

LECTURESHIPS/SENIOR LECTURESHIPS/ASSOCIATE PROFESSORSHIPS

DEPARTMENT OF BIOLOGICAL SCIENCE

(3 posts)

(a) Botany (2 posts): Applicants must have a first degree and a PhD and/or research experience in some aspect of plant science. The successful candidates will be required to contribute to undergraduate courses in general botany, plant taxonomy and plant physiology in the Department of Biological Sciences. Applicants from any area of botanical science will be considered but the areas of special preference are those of: (i) Systematic botany, where candidates with experience of the flora of Central and Southern Africa will be of particular interest; (ii) Plant physiology particularly plant growth, water relations or seed physiology.

(b) Nematology/Soil Zoology (1 post): Applicants should be experienced in the general area of Nematology and/or Soil Zoology. Any area of specialisation within these disciplines will be considered but preference will be given to candidates with research experience with plant-infecting or other soil-inhibiting nematodes. The successful candidate should have a first degree in some aspect of biological or agricultural science and a PhD and/or research experience in the appropriate area of specialisation. He/she will be required to contribute to undergraduate courses in invertebrate zoology, parasitology and soil ecology and to appropriate postgraduate courses.

Salary Scales (Under Review): Lecturer: Z$9,936 × 432 — Z$15,120 × 468 — Z$15,588 × 480 — Z$16,548; Senior Lecturer: Z$17,028 × 480 — Z$19,428; Associate Professor: Z$17,508 × 480 — Z$19,908; Professor: Z$19,452 × 612 — Z$20,676 × 840 — Z$23,196.

Appointment on above scales according to qualifications and experience.

Conditions of Service: Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis with an initial contract period of two years. Short-term contracts may, in exceptional cases, be extended.

Application forms and further particulars on the above posts can be obtained from the Director, Appointments and Personnel, University of Zimbabwe, PO Box MP 167, Mount Pleasant, Harare, Zimbabwe, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date for receipt of completed applications forms is 1 June 1984.

(W961)A

HONG KONG BAPTIST COLLEGE

Head of Physics Department

Applicants should have (a) a relevant academic/professional qualification of at least an MA degree, preferably a PhD degree; (b) at least 6 years of post-qualification teaching with a strong basic physics training and preferably further experience in Applied Physics and/or Industrial Research. Duties will include teaching and engaging in research work of related subjects and other departmental administrative work.

Salary Scale: HK$14,660 to HK$19,030 per month by 6 increments. (starting salary will be commensurate with qualifications and experience).

Benefits: Passages to overseas appointee and other fringe benefits including Superannuation (College 15%, appointee 5%), long leave (about 3 months after every 21 months of service), subsidized housing and medical and dental benefits for appointee and family; and where appropriate children's education allowance and passages.

Please send detailed résumé and other relevant credentials to Personnel Office, Hong Kong Baptist College, 224 Waterloo Road, Kowloon, Hong Kong. (W955)A

PLANT BREEDING INSTITUTE

MARIS LANE TRUMPINGTON
CAMBRIDGE CB2 2LQ

MOLECULAR BIOLOGISTS

required to participate in a project funded for 3 years by the Rockefeller Foundation to explore whether viral genes introduced into plant chromosomes can induce resistance to subsequent viral infection. The work will involve the cloning and characterisation of plant viral genes, the insertion of these genes into Ti plasmid vectors and describing the transcription of such genes in transformed plants.

Appointment will be at Higher Scientific Officer (salary £7,149 to £9,561 pa). Qualifications are a first or upper second class honours degree in molecular biology or related subject with at least two years' relevant experience. Reference CYT/164.

SCIENTIFIC OFFICER

required to join the winter wheat breeding team. The principal responsibility of the person appointed wil be to check the uniformity of advanced breeding lines of winter wheat with respect to segregation for important agronomic characters, including disease resistance and grain quality, in preparation for the generation of nucleus pure stocks. These stocks will have to meet statutory requirements for distinctness, uniformity and stability. The team is led by J Bingham Esq FRS.

Appointment will be at Scientific Officer (salary £5,682 to £7,765 pa). Qualifications are a degree in Agricultural Botany or a related subject, preferably with relevant post qualifying experience in experimental work with field crops. Reference CER/168.

Non-contributory pension scheme and pending pay awards apply to both posts.

Applications with curriculum vitae and the names and addresses of three referees for the first post and two for the second should be sent to the Establishment Officer by 24 May 1984, quoting the appropriate reference.

The Plant Breeding Institute is an Equal Opportunities Employer. (1874)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF PSYCHIATRY

LECTURESHIP

(Non-Clinical)

Applications are invited from suitably qualified science graduates for appointment to a post of Lecturer in the Department of Psychiatry, available from 1st October 1984. This non-medical post will provide for the permanent appointment in a clinical department of a scientist who will have the opportunity to pursue relevant research in the department's main research interests concerning the functions of some neuropeptides and biogenic amines in brain. Candidates should have several years post-doctoral research experience, particularly in advanced anatomical techniques (eg immunocyto-chemistry, axon tracing) at light and electron microscope level, and some experience of current neurochemical methods employed in the study of aminergic or peptidergic function would be advantageous.

Salary will be at an appropriate point on the Lecturers' Non-Medical scale: £7,190 — £14,125 per annum according to age, qualifications and experience.

Further particulars may be obtained from the Senior Assistant Registrar (Establishments) (FP), The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (three copies), together with the names and addresses of three referees, should be lodged not later than 22nd May 1984. Please quote reference N. (1920)A

MULTIPLE MIRROR TELESCOPE OBSERVATORY

STAFF ASTRONOMER

Applications are solicited for the position of staff astronomer at the Multiple Mirror Telescope (MMT) Observatory, a joint facility of the Smithsonian Institution and the University of Arizona, located on Mt Hopkins 60 km south of Tucson, Arizona.

Applicants should have a PhD degree in astronomy or physics and should have extensive experience in optical or infrared astronomical instrumentation. MMTO staff astronomers will be expected to guide the development of state of the art instrumentation for use on the MMT by a large community of users. Astronomical spectrographs, detectors, minicomputers for data acquisition and reduction, (hardware and software), microwave data transmission, and optical and IR interferometric instrumentaiton are areas in which expertise is being sought.

MMTO staff astronomers will spend a large fraction of their time in service to the user community, but are also expected to maintain a vigorous program of astronomical research using the MMTO. Résumés of the applicant's qualifications, along with names of three references, must be received by May 31, 1984 at the following address: Director, MMTO, PO Box 21084, Tucson, Arizona 85720. The University of Arizona and the Smithsonian Institution are Equal Opportunity, Affirmative Action Title IX/Section 504 Employers. (NW449)A

Fermentation/Culture Improvement

International Process Development Group

Pfizer, one of the world's leading pharmaceutical companies, is a multi-national organisation with world-wide manufacturing facilities producing an extensive range of science based products, many of which are made by fermentation.

The International Process Development Group based at Sandwich in Kent is responsible for the development of novel approaches to the fermentation and recovery process used in International Production, covering all major plants outside of the U.S.A. Due to expansion we are currently seeking two new important additions to this group.

A Fermentation Technologist

is required to join the Fermentation Process Development Section. You will join a dedicated team, equipped with a range of modern fermenters, involved in the development, optimisation and scale-up of fermentation processes at both laboratory and plant scale. You should hold a good honours degree in a relevant subject and ideally have a post graduate qualification or previous industrial experience. Our commitment to advancing with technology would make an appreciation of computer control for the optimisation of fermentation processes an advantage.

A Microbiologist/ Biochemist

is required within the Culture Improvement Section. The successful candiate will join an established team using both conventional and recombinant DNA approaches to strain improvement on Streptomyces species. Applicants should have a good honours degree in biochemistry, microbiology or a related subject, preferably with a post graduate qualification and/or relevant industrial or academic expedrience.

These challenging appointments offer a highly competitive basic salary plus a bonus related to personal performance. We also offer generous help with relocation.

Pfizer

We employ some 1400 people, of whom over 250 are graduates, on our Sandwich site which is in pleasant rural surroundings, close to coastal resorts, championship golf courses, the Continent and good sailing waters. We have a thriving Sports and Social Club with first class amenities.

If you are interested in the appointments please send your curriculum vitae, in confidence, to Dr. M.C. Hall, Senior Personnel Officer, Pfizer Limited, Sandwich, Kent CT13 9NJ.

(1955)A

WEST VIRGINIA UNIVERSITY

invites applications and nominations for the position of

DEAN OF THE COLLEGE OF OF AGRICULTURE AND F...ESTRY AND DIRECTOR OF THE AGRICULTURAL AND FORESTRY EXPERIMENT STATION

The Dean is responsible for all educational, research, extension and service programs of the College and Experiment Station. Qualifications include an earned doctorate, a record of academic and research excellence, a firm commitment to the mission of a comprehensive land grant university and ability to communicate effectively with faculty, staff, students and representatives of commodity groups. Demonstrated administrative leadership is desired.

Applications including a résumé, other supporting material and names of three references will be accepted t... July 15, 1984. Nominations and a... ications should be addressed to: Chairman of Search Committee, School of Dentistry, Medical Center, West Virginia University, PO Box 6305, Morgantown, West Virginia 26506-6305.

West Virginia University is an Affirmative Action, Equal Opportunity Employer. (NW497)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF PHYSICS

RESEARCH FELLOW

Applications are invited for the position of post-doctoral research assistant within the Condensed Matter Group in the Physics Department. The research activities of this group lie largely in the field of phase transitions and critical phenomena, and the successful applicant will be expected to engage in theoretical work in this area, with particular emphasis on Monte Carlo studies using the Edinburgh Distributed Array Processors. Experience in the area of phase transitions and with computing would be an advantage.

The position, which is supported by the SERC, is available for a period of up to three years, and the appointment will be made on the 1A scale at a point commensurate with age and experience.

Applications, giving full details of the candidate's qualifications and research interests, should be sent to: Dr A D Bruce, Physics Department, James Clerk Maxwell Building, Mayfield Road, Edinburgh EH9 3JZ.

Applicants are requested to arrange for letters of support from two referees to be sent directly to the above address.

Please quote reference No 5168. (1928)A

THE UNIVERSITY OF NEW ENGLAND

DEPARTMENT OF ANIMAL SCIENCE

LECTURER/SENIOR LECTURER IN GENETICS

Applications are invited for a tenured position in Genetics. Duties will include undergraduate teaching in Genetics and animal breeding, supervision of honours and postgraduate students and research.
The applicant should have a broad knowledge of Genetics, with particular expertise in quantitative genetics and its applications in animal breeding, some preference will be given to applicants with research experience in theoretical quantitative genetics. Applicants should have a science, agriculture or veterinary degree and appropriate postgraduate qualifications. The Department is well-equipped for Genetic research and is responsible for all Genetics teaching in the University.
Appointment to commence as soon as possible.

Further information may be obtained from the Head of Department, Professor J.S.F. Barker, by writing or telephone (067) 73 2225.

Salary: Lecturer: A$23,394-A$30,734
Senior Lecturer: A$31,390-A$36,585
Closing Date: 4th June, 1984
Position No: 468
The appointment will be to the permanent staff but the University reserves the right to make the appointment probationary where it considers this appropriate.
Other conditions include superannuation, assistance with travel and removal expenses and with buying or building a house in Armidale.

Applications including the names and addresses of three referees and stating the position number should be sent to the Staff Officer, University of New England, Armidale, N.S.W. 2351, Australia, prior to the closing date. Applicants should forward a copy of this advertisement to their referees and ask them to send their reports direct to the Staff Officer, Mr. B.G. Turner, marking their envelopes "Private and Confidential" and quoting the position number, before the above closing date so as to expedite the appointment process.

Armidale NSW 2351, Australia (W962)A

Kumpulan Guthrie Sendirian Berhad, a leading Malaysian Plantation Group with diversified interests

Requires

BIO-TECHNOLOGIST
(TISSUE CULTURE SCIENTIST)

Responsibilities: The successful applicant will be responsible for developing tissue culture techniques for oil palm and other tropical plantation crops for large scale commercial production.

Qualifications: Applicants should have a PhD or Masters Degree in Biological Science or a related discipline to tissue culture. A minimum of 3-5 years experience in developing tissue culture techniques is required preferably in oil palm or other plantation crops.

Applications: Applications must include photocopies of all degrees, reference letters from all previous employers and a full curriculum vitae.

Address applications to:

The Associate Director, Personnel
Kumpulan Guthrie Sendirian Berhad
P O Box 12516, Kuala Lumpur
MALAYSIA. (W944)A

ETH ZÜRICH

The Swiss Federal Institute of Technology in Zurich has an opening for the faculty position of

PROFESSORSHIP in EXPERIMENTAL ATMOSPHERIC PHYSICS

The teaching duties of the new professor will include advanced courses in atmospheric physics for science graduates and basic meteorology courses for engineering and science students. In research, emphasis is to be placed on experimental (including field measurement) work in basic or applied atmospheric physics in one (or more) of the following areas: boundary layer processes, cloud physics, regional circulation systems, aerosols and air pollution problems.

The successful applicant will have gained considerable scientific experience after university graduation and demonstrated ability to perform high quality research. He will be prepared to teach at all university levels and to cooperate both with colleagues within the university and with other institutions.

Applications, with curriculum vitae and list of publications, should be submitted before June 30, 1984, to the President of the Swiss Federal Institute of Technology, Prof. H Ursprung, ETH-Zentrum, 8092 Zurich. (W963)A

BRUNEL UNIVERSITY
Faculty of Mathematics and Science
Department of Applied Biology

'NEW BLOOD' LECTURESHIP

This post is in a department where the research interests are mainly concerned with fundamental biomedical science. The successful applicant will have already demonstrated substantial research potential in this area with post-doctoral experience in cell biology. It is envisaged that he/she will form a link between two major research groups: the Cell Biology Unit (Dr Roger Dean) with major interests in macrophages, proteolysis and the biological effects of free radicals; and the Parasite Immunology Unit (Professor Roland Terry) with major interests in the immunoconfusion accompanying some parasitic infections and other immune evasion mechanisms. In the first instance the appointee will probably be engaged in characterising the disordered mononuclear phagocytes which are present in certain experimental parasitic infections. The person appointed will be expected to teach appropriately in the Cell Biology sections of the enhanced undergradute degree courses in Applied Biology and Applied Biochemistry and also to contribute to the teaching of the postgraduate course in Applied Immunology.

Applicants must be under 35 years on 1 October 1984 and not presently occupying a UGC funded teaching post. Salary will be in the Lecturer scale £7,190 – £14,125 per annum, plus £1,186 per annum London Allowance, with USS benefits.

Requests for additional information and to visit the Department should be made to Mrs Ann Johnston, Department of Applied Biology, Tel: Uxbridge (0895) 37188 ext 646.

Letters of application, accompanied by full curricula vitae and the names of three referees, should be addressed to the Personnel Secretary, Brunel University, Uxbridge, Middlesex UB8 3PH, by 25 May 1984.

Brunel University is an Equal Opportunity Employer. (1882)A

RESEARCH Associate position in molecular endocrinology for a physician/scientist with experience in insulin receptor biosynthesis, processing autophosphorylation mechanisms and clinical abnormalities. Send C vitae and three references to: Donald F Steiner, CLSC 739 Department of Biochemistry, 920 E 58th St, Chicago, IL 60637. (NW499)A

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY
MEDICAL SCHOOL
QUEENS MEDICAL CENTRE
RESEARCH ASSISTANT
(readvertisement)

Applications are invited for a Wellcome Trust Funded Research Assistantship to carry out a study of the effect of histamine agonists and antagonists on the release of catecholamines and indoleamines in the CNS.

Experience in the methods of HPLC or neurotransmitter release would be desirable.

The appointment is available from August 1984, for one year, in the first instance, renewable for a further two years with a salary in the range of £6,310 to £7,190 per annum.

Enquiries may be made to Dr S J Hill or Dr R Mason on (9692) 700111 ext 3525. Two copies of a letter of application and a curriculum vitae, naming two referees, should be sent as soon as possible to Dr S J Hill/Dr R Mason, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Clifton Boulevard, Nottingham NG7 2UH. (1891)A

POSTDOCTORAL RESEARCH ASSOCIATE POSITION

available immediately to study the Biochemistry of Exocytosis in the Chromaffin Cell. Protein phosphorylation, calcium-binding proteins, and membrane interactions. See J C B 91: 247 and J B C 258: 14664.

Send Curriculum Vitae and names of references to Dr Carl E Creutz, Department of Pharmacology, University of Virginia, Charlottesville, Virginia 22908. An Equal Opportunity/Affirmative Action Employer. (NW501)A

UNIVERSITY OF GLASGOW
DEPARTMENT OF GENETICS
POSTDOCTORAL POST

A Postdoctoral position is available in the Department of Genetics for years from October 1984, to work with Dr Howard Jacobs on the Isolation and Characterisation of Nuclear-coded Mitochondrial Genes from Mammalian Cells. This research is funded by an MRC Project Grant, and salary will be at the appropriate point on Range 1A of the scales for Research and Analogous Staff, plus USS benefits.

Applicants should be familiar with somatic cell genetics and/or recombinant DNA technique.

Applications, including full curriculum vitae and the names of two referees, should be sent to Dr H T Jacobs, Department of Genetics, University of Glasgow, Glasgow G12 8QQ before 31st May 1984.

In reply please quote Ref No 5242M. (1903)A

INSTITUTE OF TERRESTRIAL ECOLOGY
RADIOCHEMIST

A Radiochemist is needed to join a small team, looking into the distribution of radionuclides in the environment. The appointee will be based at the Institute's Merlewood Research Station, Grange-over-Sands, Cumbria and will be responsible for the radiochemical laboratories and counting instruments, for the development of radiochemical techniques and, with assistance, for the determination of alpha and gamma emitters in ecological materials. There will be opportunity to contribute to the research programme.

QUALIFICATIONS AND EXPERIENCE: The minimum qualification for the post is an honours degree. Previous experience is essential.

SALARY: The appointment will be to Higher Scientific Officer/Senior Scientific Officer grade with a salary scale of £7,149 — £9,561 for HSO or £8,970 — £11,476 for SSO. Starting salary will be according to age, qualifications and experience.

The Natural Environment Research Council is not a government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from: Establishment Section, Institute of Terrestrial Ecology, 68 Hills Road, Cambridge CB2 1LA, (Tel: 0223 69745).

Please quote reference number 229. The closing date for applications is 18 May 1984. (1912)A

Natural Environment Research Council

THE UNIVERSITY OF CALGARY
NEUROANATOMIST

Applications are invited for a NEUROANATOMIST in the Department of Anatomy and the Neuroscience Research Group in The University of Calgary, Faculty of Medicine. Appointment at Assistant or Associate Professor, salary on University scale will be determined according to experience and qualifications. Requires MD or PhD, at least two years post-doctoral research training, evidence of a productive and fundable neuroanatomical research program, and experience teaching medical and graduate neuroanatomy. Primary duty will be to establish and conduct an original, independent research program of interest to a large and diverse interdisciplinary neuroscience group. Teaching in medical and graduate neuroanatomy will also be required. The position to be funded by successful competition for a Scholarship from the Alberta Heritage Foundation for Medical Research.

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents.

Applications must be received by May 31, 1984, with appointment to be effective in 1985.

Please send a curriculum vitae, statement of research interests and career goals, and the names of three referees to: Dr Gregory E Lucier, Chairman, Neuroanatomy Search Committee, Department of Medical Physiology, The University of Calgary, Faculty of Medicine, 3330 Hospital Drive NW, Calgary, Alberta T2N 4N1. (NW494)A

GLASSHOUSE CROPS RESEARCH INSTITUTE
CROP PROTECTION DIVISION
BIOTECHNOLOGICAL APPROACHES TO STRAW UTILIZATION

Two vacancies are to be financed by the Agricultural Genetics Company for 2 years with possible extension.

1 A Microbiologist/Plant Scientist (grade HSO I/SSO) is required to isolate microbial inoculants to hasten straw biodegradation. Small-scale testing of their efficacy under laboratory conditions will be undertaken.

2 A Microbiologist/Soil Scientist (grade HSO II) is required to produce and formulate existing microbial inoculants for production on a scale suitable for field-scale testing.

Qualifications required are first or upper second class honours degree with 2-4 years relevant post-qualifiying experience for HSO I/SSO grade and a degree or HNC in a relevant subject with at least five post-qualifying years relevant practical experience for the HSO II grade.

Salary £7,149 — £9,561, HSO grade; £8,970 — £11,476 SSO Grade, depending upon qualifications and experience. Non-contributory superannuation scheme. Annual leave 22 days.

Application forms and further details from Administrative Assistant, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, W Sussex BN16 3PU.

Closing date for applications — 18 May 1984. (1933)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL
FOOD RESEARCH INSTITUTE
Microbiology Division

Post No. 83/26 SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER

A MICROBIAL GENETICIST is required to work in a group studying the genetics of methanogenic bacteria. The long term objectives of the group are to develop gene transfer systems, so that strains of methane producing bacteria of improved efficiency in anaerobic digestion processes may be produced.

Methanogens are rigorous anaerobes which can only be cultured in conditions of strict anaerobiosis. Genetics methods are not yet established and techniques applicable to Eubacteria may not be directly applicable to these Archaebacteria. The immediate aims are to produce genetically marked strains, to isolate potential vectors and to establish techniques for generating viable protoplasts.

Qualifications:
First or upper second class honours degree in a relevant subject, with at least 2 years relevant post-qualifying research experience in microbial genetics for appointment at Higher Scientific Officer level, and preferably a PhD.

Nutrition and Food Quality Division

Post No. 84/1 SCIENTIFIC OFFICER

This post is one of two such posts in the Intake Measurement Group. The person appointed will be concerned with studies of food intake using a variety of techniques and the preliminary processing of data from these studies. The post calls for an interest in, and an aptitude for, working with people and some dietetic experience is desirable. The studies will be primarily conducted in the Norwich area; a valid driving licence is necessary.

Qualifications:
A degree in Nutrition of Dietetics with some dietetic experience.

Salary scales: Scientific Officer: £5,682 – £7,765. Higher Scientific Officer: £7,149 – £9,561.

Non-contributory superannuation scheme.

The Agricultural and Food Research Council is an Equal Opportunities Employer.

Further particulars and application forms from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA, quoting the appropriate reference number. Closing date: 18 May 1984.

UNIVERSITY OF BATH
SCHOOL OF BIOLOGICAL SCIENCES

Applications are invited for a
POST-DOCTORAL APPOINTMENT

to start on October 1st, tenable for 3 years, to work on an SERC funded project investigating the influence of opioid substances on endocrine function in fishes.

Applicants should hold a PhD and have experience in hormone assays and/or histology.

Salary up to £8,530 pa according to qualifications and experience.

Application forms from the Personnel Officer, University of Bath, Bath, BA2 7AY, quoting ref no: 84/60. Closing date: 21.5.84. (1911)A

CHARING CROSS HOSPITAL MEDICAL SCHOOL
(University of London)
RESEARCH ASSISTANT

Applications are invited for a three year post funded by the Wellcome Trust to work with Dr A K Allen in the Department of Biochemistry on the structure, function & Biosynthesis of cell surface glycoproteins of Trypanosoma cruzi and related protozoa. Previous experience of work on membrane glycoproteins is preferred, but experience of parasitic protezoa is not essential.

Starting salary between £6,310 and £7,630 plus £1,186 London Allowance according to age and qualifications.

For application forms & further details please write to Dr Allen, Department of Biochemistry, Charing Cross Hospital Medical School, Fulham Palace Road, London W6 8RF, within 2 weeks of the appearance of this advertisement. (1893)A

DIVISION OF RESEARCH RESOURCES
NATIONAL INSTITUTES OF HEALTH
PUBLIC HEALTH SERVICE
DEPARTMENT OF HEALTH AND HUMAN SERVICES

The National Institutes of Health (NIH), Division of Research Resources (DRR) invites nominations and applications for the position of Health Scientist Administrator (Biomedical Sciences), GM-601-14 in the Biotechnology Resources Program Branch (BRP).

This is a Civil Service position with a salary range of $42,722 to $55,538 per annum.

The Biotechnology Resources Program Branch is responsible for the administration of a program currently supporting resource centers which serve as regional and national resources for the acquisition, development and maintenance of ultrasophisticated technologies including instruments, and application of the technologies to study biomedical research problems. The Health Scientist Administrator is responsible for the administration of assistance and procurement awards to the centers. The administrator conducts visits to grantee or potential grantee institutions, plans workshops, symposia and other *ad hoc* meetings, and serves as Executive Secretary of the Biotechnology Resources Review Committee.

Applicant must possess research experience in biomedical computer sciences or biomedical engineering, and meet the minimum requirements for Health Scientist Administrator:
(a) Minimum educational requirements requires a Ph.D. (or equivalent) in a academic field of science allied to health or health related research, *plus*
(b) One year of experience in research program administration in which professional judgments require the application of scientific knowledge of health or health related research to plan, review, and evaluate research projects, and to access accurately the significance of results and progress accomplished.

Further information concerning the position and qualification requirements may be obtained by contacting Ms. Pathenia A. Wiggins at (301) 496-1524. Applications (Personal Qualifications Statement, SF-171) accompanied by a current curriculum vitae and bibliography should be submitted to Ms. Wiggins at the DRR Personnel Office, National Institutes of Health, Building 31, Room 5B06, 9000 Rockville Pike, Bethesda, Maryland 20205. Applications should be post marked no later than May 31, 1984.

Applications from women and minority group members are especially solicited.

THE NATIONAL INSTITUTES OF HEALTH IS AN EQUAL OPPORTUNITY EMPLOYER.

(NW498)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF APPLIED MATHEMATICS

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above three year appointment commencing 1 October 1984 at an initial salary in the range £7,190 to £7,630 per annum, plus USS.

The post is funded by an SERC Research Grant and will involve the theoretical study of radio frequency heating of magnetically confined plasmas as part of a programme of research being carried out in collaboration with UKAEA Culham Laboratory. Some knowledge of plasma physics or a related discipline and the use of computers would be an advantage.

Further particulars may be obtained from the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ, to whom applications (two copies preferably in typescript), including c v, list of publications and the names of two referees should be sent to arrive not later than 25 May 1984. (1948)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF BIOCHEMISTRY

ELECTROCHEMIST/ BIOCHEMIST

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from suitably qualified individuals to work with Dr P R Rich on a project funded by the Venture Research Unit of British Petroleum Company p.l.c. The work will involve the application of electrochemical and spectrophotometric techniques to aspects of biological electron transfer processes, particularly those of photosynthesis and respiration. An electrochemist with an interest in biological systems, or a biochemist with a chemical background, would be most suitable.

The post is available immediately for up to three years with a starting salary of £8080 (under review) according to age and experience. Further details of the project may be obtained from Dr Rich. Applications containing a curriculum vitae and the names of two referees should be sent as soon as possible to The Superintendent, Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge CB2 1QW. (1946)A

SCIENTIFIC EDITOR

The Society for General Microbiology has vacancies for persons to assist in the editing and production of its scientific publications which include the *Journal of General Microbiology* and the *Journal of General Virology*. An interest in scientific publishing and information exchange is essential and some previous publishing experience would be an advantage. Applicants should have a degree in microbiology, biochemistry or a related science, a good command of English and a keen eye for detail. Starting salary will be in the range £6,310 – £7,190 on a scale rising to £9,875 (linked to University Administrative Grade IB). The person appointed would be expected to work in Reading and to live in the neighbourhood.

Applications in your own handwriting, together with a curriculum vitae and the names of two referees, should be sent to Dr C. Sinclair, Harvest House, 62 London Road, Reading, Berkshire RG1 5AS, from whom further details may be obtained on request.

(1909)A

THE UNIVERSITY OF WISCONSIN – MADISON

CELLULAR/MOLECULAR BIOLOGIST

invites applications for a tenure-track faculty position in the general area of structural cellular or molecular biology beginning on or after 1 January 1985. The appointment could be made at the Professor, Associate Professor or Assistant Professor level, depending on the qualifications of the candidate. The candidate would be expected to carry on an active research program and serve as Director of the High Voltage Electron Microscope (HVEM) Laboratory or, in the case of an appointment at the Assistant Professor level, be prepared to assume the Directorship in the future. The HVEM Laboratory is a National Biotechnology Resource providing specialized instrumentation for biomedical structural research including a 1 MeV electron microscope, facilities for electron crystallography, and with plans for the addition of low-voltage scanning electron microscopy and video-enhanced light microscopy. The candidate's research should be directed at a fundamental biological or biomedical problem and might employ, for example, electron crystallography, image analysis of macromolecular complexes or analysis of cell structure. Depending on the background and research area of the candidate the appointment would be entirely or in part in the Department of Anatomy, Biochemistry, Oncology, Pathology, Zoology or in the Laboratory of Molecular Biology. Teaching responsibilities would be determined through the appointing Department.

Applicants should submit, by 1 July 1984, a curriculum vitae, statement of research plans and names of three references to: Professor Gary G. Borisy, Chairman, Laboratory of Molecular Biology, 1525 Linden Drive, University of Wisconsin, Madison, Wisconsin 53706.

An Affirmative Action/Equal Opportunity Employer. (NW496)A

BRITISH GEOLOGICAL SURVEY

(Formerly Institute of Geological Sciences)

COMPUTER CO-ORDINATOR

The Survey has a vacancy for a Computer Co-ordinator at its Edinburgh offices where a PRIME 550 computer is operated on behalf of the Department of Energy as a satellite of a master installation in London and where a data base related to geological exploration of the UK Continental Shelf is currently being installed.

The successful candidate will be responsible to the Hydrocarbon Data Administrator for:

1. **Installation**
   Support, security, maintenance and documentation of the system.
2. **Staff**
   Management of the operator(s)
3. **Programming**
   (a) systems: to optimise and enhance usage of the installation.
   (b) Applications: implementation, modification and support of digitising and graphics program packages.

Applicants should have a degree in a relevant subject and at least 5 years computing experience.

The successful candidate will join at Senior Scientific Officer level (£8,970 – £11,476 pa). Salaries are under review.

The appointment will be for a period of three years after which service in NERC Computing Service may be possible.

NERC is not a government department but conditions of service are similar to those of the Civil Service.

For further details and an application form, write to recruitment Section, British Geological Survey, Keyworth, Nottingham NG12 5GG.

Closing date for receipt of completed application forms is 17 May 1984. Please quote reference SS/ CI/ GT/ 1.

Natural Environment Research Council

(1883)A

POSTDOCTORAL POSITION

available 1 May 1984 for a

CRYSTALLOGRAPHER

interested in the determination of linear polymer structures. Research involves the quantitative use of electron diffraction intensity data from microcrystalline preparations for crystal structure analysis and affords the opportunity to learn unusual aspects of diffraction physics not frequently encountered in X-ray crystallography. Familiarity with X-ray crystal structure analysis and computing is most desirable and some knowledge of electron microscope operation would be useful, but is not essential. Initial appointment is for one year with extension negotiable. Salary is ca $15,000/annum.

Applicants should send curriculum vitae and three references to: Dr D L Dorset, Electron Diffraction Department, Medical Foundation of Buffalo, Inc, 73 High Street, Buffalo, New York 14203.

(NW500)A

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Division of Immunology

Applications are invited for a postdoctoral position in the Division of Immunology to work with Dr G.G.B. Klaus on early events in the activation of B lymphocytes by various agents. The appointment will be for 3 years from 1st October 1984. Experience in tissue culture and/or biochemistry would be advantageous.

The salary will be in the range £8530 – £10250 per annum plus £1186 London allowance, with superannuation provision.

Applications should include a curriculum vitae and the names of two referees and should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 8th June 1984 quoting ref: IMM/10/H.

(1936)

CAMBRIDGESHIRE COLLEGE OF ARTS AND TECHNOLOGY

PRINCIPAL LECTURER IN GEOLOGY

(Head of Geology)

Required to lead the Geology Section within the Department of Science.

Applicants should possess a PhD in Geology or a related subject, be experienced in teaching Geology to honours degree level, and be active in research.

The ability to teach one or more of the following to honours degree level will be a distinct advantage: economic geology, geophysics, engineering geology, other applied or industrial aspects of geology.

Salary (under review): £12,519 – £13,938 (Bar) – £15,744.

Details and forms, to be returned by 18th May 1984, from Administrative Assistant, Department of Science, CCAT, East Road, Cambridge CB1 1PT. Tel (0223) 352992.

(1939)A

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

DIVISION OF BIOCHEMISTRY

Applications are invited for a postdoctoral position in the Division of Biochemistry to work with Dr N. M. Green, FRS. The project is in the field of protein chemistry and applicants should preferably have some experience in organic chemistry. The aim of the project will be to develop new photochemical reagents for labelling and identifying functional sites of the Ca^{++} transporting ATPase of sarcoplasmic reticulum and related proteins. Parallel work on crystallisation is also envisaged. The salary will be in the range £8,530 – £10,250 per annum plus £1,186 London allowance, with superannuation provision.

Applications should include a curriculum vitae and the names of two referees and should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 31st May 1984 quoting ref: BCH/6/M. (1930)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF APPLIED MATHEMATICS

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above three year appointment commencing 1 October 1984 at an initial salary in the range £7,190 to £7,630 per annum, plus USS.

The post is funded by an SERC research grant and will involve the theoretical study of radio frequency heating of magnetically confined plasmas as part of a programme of research being carried out in collaboration with UKAEA Culham Laboratory. Some knowledge of plasma physics or a related discipline and of the use of computers would be an advantage.

Further particulars may be obtained from the Establishments Officer, The University, College Gate, St Andrews, Fife KY16 9AJ, to whom applications (two copies preferably in typescript), including C.V., list of publications and the names of two referees, should be sent to arrive not later than 25 May 1984.

(1901)A

UNIVERSITY COLLEGE LONDON

"NEW BLOOD" LECTURESHIP

EXPERIMENTAL PATHOLOGY

Applications are invited for the above Lectureship in the Department of Experimental Pathology under the UGC's "New Blood" initiative. The post is available from 1st October 1984 and candidates should normally be aged 35 or under.

Applicants should be in the position of initiating and carrying out a research programme in the field of the transport and chemical processing of viral proteins within cells.

Salary in range £7,190-£14,125 per annum (under review) plus £1,186 per annum London allowance.

Applications (no forms), including a full cv and names and addressed of two referees, should be sent to: Assistant Secretary (Personnel), University College London, Gower Street, London WC1E 6BT by no later than 8 June 1984. (1950)A

INSTITUTE OF CANCER RESEARCH

There is a vacancy for a

POST-DOCTORAL SCIENTIST

to work in the Institute's Radiotherapy Research Laboratories at Sutton, Surrey. The successful applicant will join a team of scientists who are investigating the radiobiology of human tumours. This is an exciting area of research at the present time in which there are good prospects for increasing our understanding of the clinical response of cancer to radiation treatment. The work will involve studies on cell suspensions, multicellular spheroids, and human tumour xenografts. The modification of radiosensitivity by drug treatment will be an important aspect of the work. Experience in radiobiology and tissue culture would be an advantage. Appointment to 31.3.86 in first instance. Salary in scale £7,190 – £9,425 pa, plus London Allowance of £1,186 pa.

Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref: 300/G/48. (1923)A

This symposium will provide a forum for critical assessment of recent developments in understanding of the molecular events in platelet stimulus response coupling. The programme has been devised to provide a comprehensive and structured view of current developments. It is hoped that such a symposium will suggest appropriate strategies in the future development of drugs to modulate platelet function.

The symposium proceedings and discussions will be published promptly. The number of participants will be limited to 250, and registration deadline is 1 August 1984. Address for detailed programme and registration form: Elizabeth Wilson, Administrative Secretary, c/o Dr. J. Westwick, Thrombosis Research Unit, King's College School of Medicine & Dentistry, Denmark Hill, London SE5 8RX, United Kingdom. Tel: 01-274 6222 ext 2442/2444.

TENTH EMBO ANNUAL SYMPOSIUM 1984
Control of Transcription in Eukaryotes

24—27 September 1984

EMBL Heidelberg (F.R.G.)

Invited speakers include:

M. E. Akam (Cambridge; V. G. Allfrey (New York); M. Beato (Marburg); P. Borst (Amsterdam); F. Cuzin (Nice); E. M. De Robertis (Basel); A. van der Eb (Leiden); H. Eisen (Paris); D. Gallwitz (Marburg); W. J. Gehring (Basel); F. G. Grosveld (London); I. Grummt (Würzburg); P. Gruss (Heidelberg); L. Hereford (Boston); A. Johnson (San Francisco); C. Kédinger (Strasbourg); W. Keller (Heidelberg); U. Laemmli (Geneva); T. Maniatis (Cambridge, USA); K. Nasmyth (Cambridge); M. S. Neuberger (Cambridge); C. S. Parker (Pasadena); M. Revel (Rehovot); R. G. Roeder (New York); W. Schaffner (Zürich); U. Schibler (Lausanne); W. T. Schrader (Houston); G. Schütz (Heidelberg); A. Sentenac (Gif-sur-Yvette); P. A. Sharp (Cambridge, USA); T. Shenk (Stony Brook); K. Struhl (Boston); G. Tocchini-Valentini (Rome); C. Weissmann (Zürich); N. M. Wilkie (Glasgow); K. R. Yamamoto (San Francisco); M. Yaniv (Paris)

Although the main theme of the Symposium is the control of transcription in eukaryotes, some aspects of RNA processing will also be discussed.

The Symposium will be at the European Molecular Biology Laboratory, Heidelberg, with registration on Sunday, 23 September 1984. Plenary sessions will be held in the mornings and evenings of 24 — 26 September, and the morning and afternoon of 27 September. There will be poster sessions in the afternoons of 24 — 26 September inclusive, to allow participants to present their work. It is also intended to organize informal workshops during the Symposium, the themes of which, depending on the posters received, may include inducible genes, cell-type specific gene expression, promoter organization and the structure of active chromatin.

Applications for participation, including a curriculum vitae, a brief description of current research interests, and a 1-page (DIN A 4) abstract of your poster, if you wish to present one, should be sent to: Dr. J. Tooze, Executive Secretary, EMBO, Postfach 1022.40, D - 69 Heidelberg, F.R.G.

The registration fee, which includes daily transport to the EMBL from Heidelberg during the Symposium, lunches, and the Symposium reception is DM 180, for graduate students DM 90, and for participants from industry DM 360. Participants will be accommodated in hotels in Heidelberg, and a small number of inexpensive rooms will be available in the EMBL Guest House. The registration fee does NOT cover the cost of accommodation.

Applications should reach Heidelberg by 1 June 1984. The facilities available make it necessary to restrict the number of participants to about 220 and, therefore, the Organizing Committee may be obliged to make a selection from the applications received. Those accepted will be notified by 31 July 1984 at the latest. The registration fee should NOT be sent until you have been notified of your acceptance for the Symposium.

Organizing Committee: L. Philipson (EMBL Heidelberg) — Chairman, M. Birnstiel (Zürich), P. Chambon (Strasbourg), R. Cortese (EMBL Heidelberg), H. Pelham (Cambridge), J. Tooze (EMBO). (W715)M

CONFERENCES and COURSES

EMBO COURSE

BIOTIN-LABELED DNA in MOLECULAR GENETICS

December 3-8, 1984

Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 place Jussieu, 75005 Paris, France.

Programme: A practical and Lecture Course detailing the preparation and use of non-isotopically labelled polynucleotide probes, hybridization procedures, (Southern dot, colony, plaque and *in situ*) will be performed. Other applications of these probes as affinity reagents for the purification of nucleic acids and proteins will be discussed.
The teaching staff will include: David Ward (Yale University, New Haven), Pennina Langer-Safer (Roche Institute, Nutley) and Laura Manuelidis (Yale University, New Haven); and researchers of the host laboratory.
Cost: There will be a $100 registration fee (not covering accommodation or boarding) payable following notification of acceptance.
Applications: A letter of application together with a short Curriculum Vitae and a statement of interests and reasons for applying should be sent to Dr. G. Bernardi before September 30, 1984 at the above address. (W946)C

continued on pages 20 & 22

STUDENTSHIPS

LUTON COLLEGE OF HIGHER EDUCATION
LEA RESEARCH STUDENTSHIP in the Geology of Stratabound Mineral Deposits

Applications are invited from graduates with a first or upper second class honours degree or from undergraduates who are likely to obtain such a qualification in the summer, for a Research Studentship funded by Bedfordshire County Council.

The successful applicant will carry out an investigation of the Palaeozoic iron-ores of Caledonides of North Wales under the direction of Dr W E G Taylor with the collaboration of Dr A V Bromley of Camborne School of Mines.

Full Curriculum Vitae to be returned to Dr Taylor, Luton College of H.E., Park Square, Luton LU1 3JU by Friday 25th May 1984.

(Beds C.C. is an equal opportunities employer) (1879)F

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS
PAEDIATRIC RESEARCH UNIT AT GUY'S
PhD STUDENTSHIP IN MOLECULAR BIOLOGY

Post available for student with very good academic record wishing to investigate, under the supervision of Dr F Giannelli, the gene defects causing deficiency of coagulation factor IX and haemophilia B. Previous project work or experience in molecular biology an advantage.

Full curriculum vitae, with the names of two referees, should be sent to the Administrative Assistant, Paediatric Research Unit, Prince Philip Research Laboratories, Guy's Tower, London Bridge, London SE1 9RT. (1906)F

MEAT RESEARCH INSTITUTE
AFRC — RESEARCH STUDENTSHIP

Applications are invited for a 3 year AFRC Postgraduate Studentship at the Meat Research Institute to study proteinase activities in muscle. The work will include the production of monoclonal antibodies for the development of immunoassays and immunohistochemical location of specific proteinase.

Candidates must hold (or expect to gain) a First or Upper Second Class Honours degree in Biochemistry or Cell Biology and will be expected to register as a Ph.D Student at the University of Bristol.

Applications forms and further details from: The Personnel Officer, Meat Research Institute, Langford, Bristol BS18 7DY. (1935)F

UNIVERSITY OF ESSEX
SERC CASE STUDENTSHIPS

Applications are invited for a CASE Studentship, tenable in the Physics Department and in collaboration with the Allen Clark Research Centre of the Plessey Company to investigate conduction processes in GaAs/(GaAl) As heterojunctions grown by MOCVD methods.

Applicants, who should possess or expect to gain a 1st or 2(i) honours degree in Physics, should send their curriculum vitae (including the names of two referees) to the Departmental Secretary, Physics Department, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, not later than 31 May 1984 quoting reference N. (1884)F

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF PHYSIOLOGICAL SCIENCES
THE MEDICAL SCHOOL

Applications are invited for an

MRC FUNDED THREE-YEAR PhD STUDENTSHIP

to investigate the origin, composition, physical and biochemical properties of middle ear effusions in chronic secretory otitis media in children. Candidates should have, or should expect to obtain, a First Class or Upper Second Class Honours Degree in Physiological Sciences, Biochemistry or a related subject.

Further details can be obtained from Dr J P Pearson, Department of Physiological Sciences, The Medical School, The University, Newcastle upon Tyne NE1 7RU, to whom letters of application including a curriculum vitae and the names of two academic referees should be sent as soon as possible. (1892)F

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF BIOCHEMISTRY
SERC STUDENTSHIP IN MICROBIOLOGICAL BIOCHEMISTRY

Applications are invited from final year students in an appropriate field, who expect to achieve first or upper-second class honours, for an award tenable for three years. The successful applicant will register for a PhD degree and will be involved in a study of the regulation of extracellular toxin formation in Staphylococcus aureus.

Applications giving details of academic record and the names of two referees should be sent to Dr G Coleman, Department of Biochemistry, Nottingham University Medical School, Queen's Medical Centre, Nottingham NG7 2UH. (1942)F

UNIVERSITY OF CAMBRIDGE
THE BIOTECHNOLOGY CENTRE
SERC BIOTECHNOLOGY PhD STUDENTSHIP

Applications are invited from graduates in appropriate disciplines for a research studentship in biosensors commencing in July 1984 and tenable for three years. The project will involve the development of immunologically-sensitised field effect transistors for application in clinical diagnostics and will be under the supervision of Dr C R Lowe.

Applicants must hold, or expect to gain, a first or upper second class honours degree and should send a curriculum vitae together with the names and addresses of two referees to Dr C R Lowe, The Biotechnology Centre, University of Cambridge, Downing Street, Cambridge CB2 3EF. (1937)F

UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH
Welsh Plant Breeding Station
ARFC RESEARCH STUDENTSHIP

Applications are invited for an AFRC Research Studentship tenable from October 1984 to investigate: "The genetic control of self and cross fertility and its manipulation in Lolium"

The successful candidate, who should possess or expect to gain a good Honours degree in Genetics, Botany or an allied discipline, will be registered with the University of Wales for a higher degree.

Applications, including the names of two referees, should be submitted before 1 June 1984, to the Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed SY23 3EB, from whom further particulars can be obtained. (1907)F

CASE STUDENTSHIP UNIVERSITY OF NOTTINGHAM/ICI CORPORATE BIOSCIENCE GROUP

A CASE Studentship is available from 1st October, 1984 to study "Heterologous gene expression in mamary cell lines". This study with transfected genomic clones will be co-supervised by Dr J Windass at ICI and Dr R J Mayer, Department of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Clifton Boulevard, Nottingham NG7 2UH.

Applications should be sent to Dr R J Mayer at the above address and should be accompanied by the names of two academic referees. (1895)F

UNIVERSITY OF ABERDEEN
INORGANIC SOLID-STATE CHEMISTRY

Applications are invited for the undernoted two CASE studentships. Applicants should hold, or expect to receive, a first or upper second class honours degree. Each studentship will lead to contact with a progressive, expanding company at the forefront of new developments in materials chemistry. Travel and subsistence will be paid for the periods which the student spends in the sponsors' laboratories.

1. Solid-state Oxide Chemistry of Ruthenium and its Compounds (In collaboration with Johnson Matthey, plc, Sonning Common, nr Reading). Ref 1222.

2. Hydrothermal Chemistry of Zirconium Dioxide (In collaboration with Cooksons Group plc, Perrivale, Middlesex). Ref 997.

Additional information can be obtained from the academic supervisor, Prof F P Glasser (Tel 0224-40241 ext 5640) and application forms obtained from the Secretary to the University, Regent Walk, Old Aberdeen AB9 1FX, as soon as possible, but in any event no later than 30 June. (1873)F

STUDENTSHIPS continued

UNIVERSITY OF NOTTINGHAM
MEDICAL SCHOOL
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY
POSTGRADUATE STUDENTSHIP

Applications are invited from those with, or who expect to obtain, a good Honours degree in Physiology, Pharmacology or a closely-related discipline, for an MRC postgraduate research studentship.

The topic of the research will be either (i) the effect of cytoplasmic calcium on glycolysis or (ii) non-invasive respiratory monitoring.

The terms and conditions of the studentship will be those pertaining to MRC Research Studentships.

Applications in writing indicating the preferred topic of research, including a full curriculum vitae and the names of two academic referees, to be sent as soon as possible to Professor A T Birmingham, Head of Department, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH. (1919)F

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY
CASE STUDENTSHIPS

Applications are invited for CASE studentships (Academic Supervisor: Dr. Colin W. Jones) to work on (i) methanol oxidation by methanotrophic bacteria (Cooperative Supervisor: Dr. M.A. Carver, I.C.I.), and (ii) the growth of energetics of Rhizobium (Cooperative Supervisor: Dr. J.W. Drozd, Shell Research).

Applications, enclosing a curriculum vitae and the names of two referees, should be sent to Mrs. J. Dean (Departmental Secretary), Department of Biochemistry, University of Leicester, Leicester LE1 7RH. (1880)F

UNIVERSITY OF KENT AT CANTERBURY
BIOLOGICAL LABORATORY
SERC CASE STUDENTSHIP

Applications are invited from students graduating in a biological science for a three year SERC CASE studentship, commencing in October 1984. The project, in collaboration with ICI, will investigate factors affecting the stability of broad host-range plasmids in bacteria, and will be supervised by Dr M F Tuite and Dr D J Hardman (Kent) and by Dr P Barth and Dr K Powell (ICI).

Further particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, University of Kent, Kent CT2 7NH, to whom completed applications and a curriculum vitae and the names of two academic referees should be submitted by Thursday, 31 May 1984. Please quote ref PG12/84/N. (1886)F

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY
MRC PARTNERSHIP STUDENTSHIP AWARD

Applications are invited (from graduates who have obtained, or are likely to obtain, a first or upper second class degree in Biochemistry) for a 3 year studentship to work on red cell membrane abnormalities associated with disease using monoclonal antibodies as molecular probes.

The studentship will commence in October 1984 and will be carried out under the joint supervision of Dr M J A Tanner, Department of Biochemistry, University of Bristol, Bristol BS8 1TD and Dr D J Anstee, Department of Immunochemistry, South Western regional Blood Transfusion Centre, Bristol BS10 5ND.

Applications (including a brief curriculum vitae and the names of two referees) should be made directly to either Dr Tanner or Dr Anstee. The successful candidate will be registered for the degree of PhD with the University of Bristol.

Applications should be made as soon as possible and not later than June 1st. (1908)F

The Queen's University of Belfast
RESEARCH STUDENTSHIP
Department of Medicine

This Medical Research Council Research Studentship is tenable for the academic year 1984/85, and renewable for up to three years. The candidate who should hold, or be expected to achieve, a good honours degree at Summer graduation will be expected to register for a higher degree. The research will be related to pancreatic and gut hormones. Applications with full curriculum vitae and the names and addresses of two refrees by 1 June to Professor K. D. Buchanan, Department of medicine, The Queen's University of Belfast, Royal Victoria Hospital, Belfast BT12 6BA, from whom further details are available. (1915)F

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF MICROBIOLOGY
MICROBIAL TECHNOLOGY GROUP
CASE STUDENTSHIP

Applications are invited from students who hold or who expect to obtain a first or upper second class honours degree in Biochemistry, Microbiology or a related subject. The project, in collaboration with the Centre for Applied Microbiology, Porton Down, involves the development of cloning and expression vectors for Bacillus subtilis.

Applications, together with a curriculum vitae and the names of two referees, should be sent to Dr C R Harwood, Department of Microbiology, The Medical School, The University, Newcastle upon Tyne, NE1 7RU, from whom further details may be obtained. (1921)F

ROTHAMSTED EXPERIMENTAL STATION
Harpenden, Herts, AL5 2JQ
PHYSIOLOGY & ENVIRONMENTAL PHYSICS DEPARTMENT
SERC CASE STUDENTSHIP: MATHEMATICAL MODELLING OF THE DRIFT OF AGRICULTURAL SPRAYS

Applications are invited for a SERC CASE Studentship tenable at Rothamsted Experimental Station and Imperial College of Science and Technology to study the drift of agricultural sprays downwind from crops. The project will involve field experiments and the use and adaptation of air pollution dispersion models.

Candidates should hold, or expect to obtain, a First or Upper Second Class Degree in Physics, Meteorology, Applied Mathematics or an Environmental Science.

Applications giving full c v and the names of two referees should be sent to: Dr H A McCartney, Physiology & Environmental Physics Department, Rothamsted Experimental Station, Harpenden, Herts AL5 2JQ by 1st June 1984 quoting Ref: 557.

We are equal opportunities employers. (1938)F

OXFORD UNIVERSITY RESEARCH LABORATORY FOR ARCHAEOLOGY

Carbon-14 dating using a 2 MV tandem accelerator, thermoluminescence dating, archaeomagnetism: studentship(s) for DPhil research, suitable for physicists, chemists, earth scientists, anticipating a good honours degree.

Details: Dr M Aitken or Dr R Hedges, 6 Keble Road, Oxford OX1 3QJ, telephone 55211. (1900)F

NUTRITIONAL CONSULTATIVE PANEL of the UK Dairy Industry is offering a POST GRADUATE STUDENTSHIP

for work, possibly leading to a higher degree in a British University or Research Institution on a Nutritional subject related to:
MILK AND MILK PRODUCTS IN THE HUMAN DIET
Examples of subjects which the Panel has identified are:

1) the role of calcium in cow's milk.

2) the role of cow's milk in the weaning of human infants.

Other subjects will be considered. Salary will follow MRC guidelines.

Apply in writing, maximum 500 words, before 31st May 1984 to: The Secretary, Nutritional Consultative Panel, Giggs Hill Green, Thames Ditton, Surrey, KT7 0EL, including proposed department where work will be carried out, curriculum vitae and names and addresses of 2 referees. (1877)F

THE QUEEN'S UNIVERSITY OF BELFAST
FACULTY OF AGRICULTURE AND FOOD SCIENCE

Applications are invited from graduates for the following awards tenable in departments of the Faculty of Agriculture and Food Science.
A: NATURAL ENVIRONMENT RESEARCH COUNCIL
1 studentship to be filled by either Department —
(a) Dept. of Agricultural and Food Bacteriology. Topic: Nitrogen fixation by the wild legume — rhizobium association.
(b) Dept. of Mycology & Plant Pathology. Topic: Basidiomycete mycorrhizal associations with turf and pasture grasses.
B: MINISTRY OF AGRICULTURE FISHERIES AND FOOD
2 Studentships awarded —
(a) Dept. of Agricultural & Food Chemistry. Topic: Denitrification in intensively managed grassland swards.
(b) Dept. of Agricultural Zoology. Topic: Potentiation of the effect of natural enemies on cabbage root fly populations.
C: SERC CASE STUDENTSHIPS
Department of Mycology and Plant Pathology available on the following topics:
"Microbial flax retting after glyphosate herbicide spraying" "(in conjunction with the Lambeg Industrial Research Association, Belfast). "Biology of soft rot erwinians on potato leaves" (in conjunction with the Scottish Crop Research Institute, Dundee).
Applicants must hold a First or Upper Second Class Honours degree in botany, biology or microbiology.
Application should be made to the Head of the relevant Department at Faculty of Agriculture and Food Science, Queen's University of Belfast, Newforge Lane, Belfast BT9 5PX. (1913)A

UNIVERSITY OF NOTTINGHAM FACULTY OF AGRICULTURAL SCIENCE
SERC CASE STUDENTSHI

Applications are invited for a th year PhD studentship, commenc in October 1984, for research on soil-plant water relations of reston opencast mining sites. This award held co-operatively with the Natio Coal Board and will form part o multidisciplinary resear programme aimed at improv restoration procedures. Applica should have, or expect to obtain 1984, a first or upper second c honours degree in an appropr science subject, preferably with sc specialism in soil science. As project involves field work, a curr driving licence is essential.

Further details may be obtai from Dr C R Black, Departmen Physiology and Environme Science, University of Nottingh School of Agriculture, Sut Bonington, Loughborough L 5RD, to whom applicatio including a full cv and the name two academic referees should be as soon as possible. (1943)

SANDOZ RESEARCH INSTITUTE

Vienna, Austria

is one of the three research centres of the SWISS based pharmaceutical company SANDOZ

A post doctoral fellowship in a research group working on the CLONING OF LYMPHOKINE GENES is available for a

CELL/MOLECULAR BIOLOGIST

with interest in the expression and function of lymphokines. Previous experience in molecular biology, immunology and/or gene cloning techniques in bacteria or yeasts will be of advantage.

The successful candidate will find excellent working conditions in well equipped laboratories. The appointment will be for an initial 2-year period. Moving expenses will be paid.

Please send cv, description of scientific experience and names of two referees to

SANDOZ

SANDOZ Forschungsinstitut
Personnel Department
Brunner Strasse 59
A-1235 Wien, Austria

(W939)E

THE UNIVERSITY OF AUCKLAND
Private Bag, Auckland,
New Zealand
POSTDOCTORAL FELLOWSHIPS

Two Fellowships are available for 12 months to be taken during 1984. Those appointed must have successfully completed the requirements for PhD or equivalent degree before taking up the Fellowship. A monthly allowance of NZ$1,805 will be paid.

PSYCHOLOGY Applicants should have had some experience in the use of small computers to control experiments in human perception and cognition. The Fellow will work with Professor M C Corballis on the relations between perception and imagery. Further information, including application forms, is available from Professor M C Corballis, Department of Psychology.

ZOOLOGY Applicants should have skills in analytical natural products chemistry, be able to devote time to the screening of extracts and have the experience to recognise novel compounds such as carotenoids, isonitriles, sterols and didemnins in marine invertebrates. The collection, identification and extraction to yield both lipid and water soluble components and analysis of extracts by TLC, GLC, HPLC, NMR and Mass spectrometry will follow. Experience in marine natural products chemistry would be an advantage. Further information, including application forms, is available from Professor Patricia R Bergquist, Department of Zoology.

15 East 26 St., New York, NY 10010

Please do not telephone. Write, including a brief synopsis of poster subject and its scientific relevance. Poster space is limited, so we suggest you act promptly.

(NW468)C

MASSEY UNIVERSITY
Palmerston North,
New Zealand
DEPARTMENT OF MICROBIOLOGY AND GENETICS
POSTDOCTORAL RESEARCH FELLOWSHIP IN GENE MANIPULATION

Applications are invited for the above position funded jointly by the NZ Forest Service and the NZ Energy Research and Development Committee to work with Dr Roy Thornton on the development of flocculent strains of pentose fermenting yeasts by genetic manipulation. Experience in gene manipulation techniques is essential and an interest in fermentation processes desirable.

The appointment is available from May 1984 or soon after for an initial period of two years, Remuneration will be NZ$25,000 per annum and some finance will be available for relocation expenses.

Further details of the position and of the University, together with conditions of appointment, may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University with whom applications close on 2 June 1984. (W958)E

UNIVERSITY OF STRATHCLYDE

Department of Metallurgy

SENIOR RESEARCH FELLOWSHIP

Applications are invited from well-qualified graduates in Physics, Chemistry or Materials Science for a Senior Research Fellowship (tenable for one year in the first instance). The successful applicant will engage in research on plasma deposition of materials under an SERC supported co-operative project with Standard Telecommunications Laboratories. Experience in Plasma-Chemical or Mass-Spectrometric techniques would be an advantage.

Salary on Range IA for Research Staff (£7,190 – £11,615 p.a.). USS benefit.

Applications, with full curriculum vitae, and the names and addresses of three referees should be sent to Staff Office, University of Strathclyde, McCance Building, 16 Richmond Street, Glasgow G1 1XQ by 25 May 1984 (quote ref: R11/84). (1944)E

THE OPEN UNIVERSITY FACULTY OF SCIENCE RESEARCH FELLOWSHIP IN EARTH SCIENCES

Applications are invited for a three year post-doctoral Research Fellowship in Geochemistry. Candidates should have a proven ability to develop rather than simply to use analytical techniques, and will be expected to make a positive contribution in this area. Present research interests in the Department include: the relationship between magma genesis and mineralisation in orogenic areas (N Chile — Bolivia, Central America and Namibia); open system differentation in high level magma chambers; and trace element enrichment processes in the upper mantle as inferred from mantle xenoliths and within plate basalts. Other specific areas of interest are the geochemistry of platinum group elements, trace element mineral analysis by microprobe and INAA, and fluid inclusion studies. The available analytical equipment consists of an ED XRF, two microprobes, INAA, and both solid source and gas mass spectrometers. Applicants are invited to submit a brief outline of their research interests.

The appointment will be for 3 years, from a starting date to be negotiated between the successful candidate and the University.

Applicants should possess a good first degree in geology and PhD in geochemistry. Salary will be on the 1A Scale for Research and Analogous Staff (£7,190 — £11,615 — under reveiw). Application forms and further particulars are available from Dr. J. W. R. Smith, Administrative Assistant (Science) (4727/2), Faculty of Science, The Open University, Walton Hall, Milton Keynes MK7 6AA or telephone Milton Keynes (0908) 652098/653993: there is a 24 hour answering service on Milton Keynes 653868.

Closing date for applications: 1st June. (1941)E

Southampton THE UNIVERSITY

DEPARTMENT OF OCEANOGRAPHY

PHYSICAL OCEANOGRAPHY/ INFRA-RED RADIOMETRY

A postdoctoral fellowship is to be supported by a NERC Remote Sensing Special Topic Award, to study the physics of the sea surface thermal skin and its importance to infra-red radiometry of sea surface temperature. The post is offered on RA scale 1A and will last until at least March 31st, 1987. Applicants should be well qualified physical science graduates with proven research experience in experimental/applied physics or physical oceanography.

Applications by 14th May to: Dr. I. S. Robinson, Department of Oceanography, University of Southampton SO9 5NH, from whom further details are available. (1924)E

THE ROYAL SOCIETY IBM RESEARCH FELLOWSHIP

Applications are invited for an IBM Research Fellowship, for research in computer science and preferably its applications including remote sensing, digital mapping and other forms of computerized data acquisition, storage and dissemination. Tenure in any appropriate university department of research institution in the United Kingdom is for two years from 1 October 1984. Applicants (restricted to citizens of the United Kingdom or the Commonwealth) must have a PhD or equivalent research experience and should preferably be under 33 on 1 October 1984. Current stipend scale: £10,829 ×£466 to £13,159 per annum with superannuation benefits.

Forms obtainable from The Executive Secretary (UMAM), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, must be returned by 31 May 1984. (1897)E

POST-DOCTORAL Fellowship: A post-doctoral position is available for candidates interested in immunology and with experience in molecular genetics, especially in gene transfer techniques, to work in a laboratory specializing in molecular analysis of cellular interactions in the immune response. Send résumé and letters of reference to: Drs Charles A Janeway, Jr and Donal B Murphy, Department of Pathology, Yale University School of Medicine, New Haven, CT 06510. (NW480)E

THE UNIVERSITY OF SYDNEY PROFESSOR HARRY MESSEL RESEARCH FELLOWSHIP IN PHYSICS

Applications are invited for the above postdoctoral fellowship for research in Physics in the University of Sydney. The following fields of research are pursued in the School of Physics: Plasma Physics (Tokamak), Solar Energy (selective surfaces), Astrophysics (synthesis radio-telescope), Astronomy (Michelson interferometer), High Energy Nuclear Physics (neutrino physics), Environmental Physics (radio telemetry) and Theoretical Physics pertaining to the foregoing experimental topics. Further information may be obtained by writing to the Head of the School of Physics.

The annual stipend shall be within the range for University of Sydney Postdoctoral Research Fellowships (currently $20,164 to $22,513 per annum). The Fellowship is tenable for one year but may be renewed from year to year.

The University reserves the right not to proceed with this appointment for financial or other reasons.

Application forms or further information may be obtained from the Registrar (Scholarships Office), University of Sydney, NSW, Australia 2006. Applications close on 31 May 1984. (W957)E

Continental European Fellowship Awards For Academic Staff

Applications are invited for awards by the CIBA-GEIGY Fellowship Trust for the academic year 1985/86.

Senior CIBA-GEIGY Fellowships

Senior CIBA-GEIGY Fellowships will be awarded to start from an agreed date during the academic year 1985/86. These will be available normally to lecturers, senior lecturers, readers or those who have held comparable permanent teaching positions for a period of at least five years in the field of chemistry, biochemistry, chemical technology, chemical engineering and biology, particularly in its relation to chemistry, at United Kingdom or Republic of Ireland universities, polytechnics, or comparable teaching institutions, who wish to undertake research at an agreed continental European university or technological university.

Awards are made for a period of six to twelve months.

Value of the awards: £9,000 per annum plus travelling expenses. CIBA-GEIGY Fellowships are intended to supplement Fellows' salaries for the period of tenure.

Further details and application forms, which should be submitted before 1 November 1984, can be obtained from The Secretary, The CIBA-GEIGY Fellowship Trust, 30 Buckingham Gate, London SW1E 6LH. (Telephone: 01-828 5676).

CIBA–GEIGY

(1898)E

MRC REPRODUCTIVE BIOLOGY UNIT, EDINBURGH

POST-DOCTORAL TRAINING FELLOWSHIP PROTEIN BIOCHEMIST

An active research team studying clinical and biological aspects of infertility and contraception offer training in gamete biology to a BIOCHEMIST with experience in the purification and characterisation of glycopeptides/glycolipids and an interest in gene technology/immunology. The research programme is designed to identify gamete specific cell surface antigens that may be used as the basis for a contraceptive vaccine. The appointment would be for three years at a salary within the range of £7,190 — £12,545 per annum.

Candidates should hold a PhD/DPhil degree or, in certain circumstances, an MSc plus at least three additional years postgraduate experience, and must meet the UK residence requirements set out in the MRC Training Fellowship regulations.

Regulations, application forms and additional information from Miss E. McKay, Administrative Officer, MRC Reproductive Biology Unit, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh EH3 9EW.

Closing date for applications — 31st May 1984. (1929)E

Pfizer Awards

In October, 1982 Pfizer Central Research at Sandwich, Kent announced that they would make up to six new Awards annually of £1,500 each to support young scientists who had carried out meritorious research at British Universities. The research should have potential application in the search for new human or animal health drugs.

The awards are made by a panel of Pfizer scientists in consultation with senior academic advisers, on the basis of work published in the two years prior to the award. The awards are NOT open to application. Each award may be renewed at the panel's discretion for a second year. The awards are for the personal use of the recipients to further their research.

The 1983 awards were announced in May 1983 and the recipients were:

Chemistry

Dr. (now Prof.) S. V. Ley, Department of Chemistry, Imperial College of Science and Technology, London.

"For his innovative synthetic work exemplified by his approach to the ionohore antibiotic X-1457A and his short synthesis of hirsutene".

Dr. P. J. Kocienski, Department of Chemistry, University of Leeds.

"For the originality of his synthesis of pederal dibenzoate and diumycinol".

Biology

Dr. J. C. McGrath, Institute of Physiology, University of Glasgow.

"For his contribution to the understanding of adrenergic and non-adrenergic transmission".

Dr. B. G. Spratt, School of Biological Sciences, University of Sussex.

"For his work on the role of the penicillin-binding proteins in growth and morphological form of bacteria".

Animal Health

Dr. D. B. Satelle, Agricultural Research Council, Unit of Insect Neurophysiology and Pharmacology, Department of Zoology, University of Cambridge.

"For his work on the pharmacology of insect receptors".

Pharmaceutical Sciences

Prof. I. W. Kellaway, Welsh School of Pharmacy, UWIST, Cardiff.

"For his work on collodial drug-delivery systems including liposomes, nano-particles and the release of drugs from semi-solid dosage forms".

Pfizer will announce the next awards later this month.

Pfizer is a worldwide, research-based company with inter-related businesses in health care, agricultural, speciality chemicals, materials science and consumer products. The Company has a major commitment at Sandwich where it employs approximately 1,500 people, over 500 of whom are engaged in new product research. (1899)N

COURSES continued

EMBO ADVANCED LECTURE COURSE (1984/ 9)

'Molecular Genetics of Mammalian Development

PAVIA, ITALY, 3-15th SEPTEMBER 1984

The Course is intended for 60 research workers or students who wish to start in the area of the Molecular Genetics of Mammalian Development. It will cover both basic concepts and the most recent findings in the field. The format of the Course will be formal lectures, seminars, discussion groups and journal clubs on a wide range of topics. The students will be provided with a book of relevant reprints. Both students and teachers will stay together at Collegio Ghislieri in the mediaeval centre of the city.

The following areas will be covered:

General topics: recombinant DNA techniques in development, germ cells, early development, dedifferentiation and its relationship to embryogenesis, developmental and temporal regulation of genes, tissue specific expression, somatic cell genetics as a tool, hormonal regulation of expression, promotors, enhancers and other regulatory elements, injection of foreign DNA into embryos and its expression, approaches in other animals.

Specific systems include: H-2, HLA and disease, antibody genes, muscle differentiation, nervous system, lens cell, X-inactivation, sex determination, the T/t locus, oncogenes and the cancer problem.

Lecturers will include: C. Morandi, V. Sgaramella (Pavia), A. Carbonara (Torino), G. Tocchini-Valentini (Roma), G. Bulfield, R. Clayton, N. Hastie (Edinburgh), A. McLaren, P. Goodfellow, M. Fried (London), M. Lyon (Harwell), P. Démant (Amsterdam), V. Pirrotta (Heidelberg), V. Chapman (Buffalo), K. Paigen (Berkeley), P. Brûlet, B. Robert (Paris), W.J. Rutter (San Francisco), O. Hägenbuchle (Lausanne).

The Course is organised for EMBO by G. Astaldi Ricotti, C. Morandi, G. Della Valle (CNR Istituto di Genetica Biochimica ed Evoluzionistica and Dipartmento di Genetica e Microbiologia, Universita di Pavia) and G. Bulfield (Edinburgh).

The fee is $280 which includes all meals and accommodation. To register, send off brief CV/ research interests (one side A4) and $50 deposit by *15th June*. Places will be allocated on 'first-come' basis) to:— Dr Grahame Bulfield (EMBO Course 1984/ 9), AFRC Poultry Research Centre, Roslin, Midlothian EH25 9PS, U.K. (Tel. 031-440 2726). (W956)C

UNIVERSITY OF LEEDS MSc IN STEROID ENDOCRINOLOGY

A course of advanced study covering one calendar year will be held in the Division of Steroid Endocrinology from October 1984 to September 1985. Applications should be made before 31st July 1984 to the Secretary at 26-28 Hyde Terrace, Leeds LS2 9LN (Tel: (0532) 454436) from whom application forms and brochure may be obtained. (1934)C

ORGANIZATION OF THE EUKARYOTIC GENOME
MOBILE ELEMENTS IN THE EUKARYOTIC GENOME
(8-12 October 1984, Montpellier, France)

A FEBS Lecture Course on the *Organization of the Eukaryotic Genome* will take place near Montpellier, France, between October 8-10. The Course will be followed by a Symposium on *Mobile Elements in the Eukaryotic Genome* (October 11-12) organized by the IUB-IUPAB Interest Group "Genome Structure and Expression".

Invited speakers include:

C. Bostock (Edinburgh), J.C. Bregliano (Clermont-Ferrand), P. Di Nocera (Naples), J. Doly (Villejuif), G. Dover (Cambridge), H. Feldmann (Münich), J. Filipski (Paris), D. Flavell (Cambridge), G. Georgiev (Moscow), G. Grimaldi (Naples), N. Hastie (Edinburgh), I. Horak (Würzburg), W. Jelinek (New York), E. Kuff (Bethesda), L. Manuelidis (New Haven), M. Meunier-Rotival (Paris), P.W.J. Rigby (London), S. Roeder (New Haven), J.H. Rogers (Cambridge), F. Rougeon (Paris), C. Schmid (Davis), J. Szoztack (Boston), B.K. Tye (Ithaca), E. Ullu (New Haven).

Attendance to both events will be limited to 120 people. Those interested in participating should contact either the Organizer of the FEBS Course, Dr. G. Roizès (Laboratoire Structure, Fonction et Evolution du Génome Eucaryote, Institut de Biologie, Boulevard Henri IV, 34000 Montpellier, France) or one of the Organizers of the Symposium, Drs. M. Singer (N.I.H., National Cancer Institute, Bethesda, Md. 20205, U.S.A.) and G. Bernardi (Laboratoire de Génétique Moléculaire, Institut Jacques Monod, 2 Place Jussieu, 75005 Paris, France). (W950)C

BIOTECHNOLOGISTS!

YOU NEED FAST AND THOROUGH COVERAGE OF RESEARCH, FINANCE, REGULATION, MARKETING AND GOVERNMENT POLICY ... WHEREVER IT TAKES PLACE.

Where can you turn to get the crucial information you need – and get it all in one stimulating publication?

Join thousands of your associates in leading corporations and institutions who benefit each month from the largest and most influential publication of its kind.

... SUBSCRIBE TO **BIO/TECHNOLOGY**
The International Journal of Biology and Industry

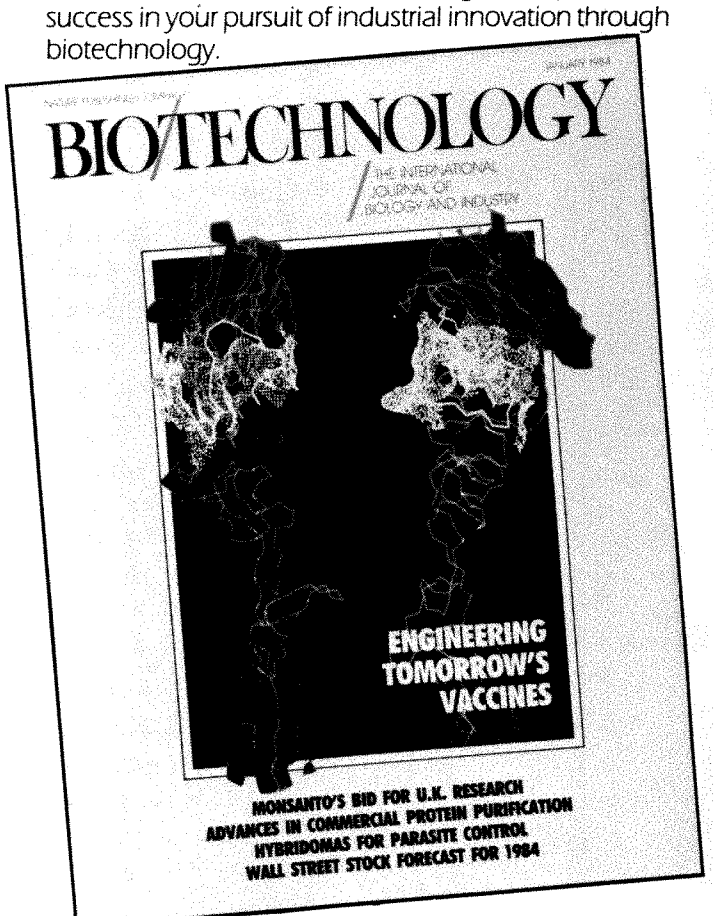
In every monthly issue, you'll find:

News reports
From correspondents around the world. New ventures, marketing agreements, research breakthroughs, new patents, government activities and types of information about your competitors that you won't find in any other publication.

Feature articles
Examining in detail new discoveries and techniques as they apply to health care, foods and beverages, chemicals, agriculture, animal health, energy and environmental management.

Profiles of leading corporations
In-depth studies of the leaders in the field.

Original research papers and reviews
Contributed each month by noted researchers in academia and industry.



Technology reports
From renowned experts in microbiology, chemical engineering, marketing, finance and government policy.

International patents
Recently issued from around the world are rapidly searched, edited and published each month.

New resources and tools of biotechnology
Presented and discussed as soon as they become available.

In just one year, **BIO/TECHNOLOGY** has become the authoritative forum for the crucial ideas, analysis and information needed for innovative research and profitable product development in biotechnology.

SUBSCRIBE TODAY to achieve the greatest possible success in your pursuit of industrial innovation through biotechnology.

Conventional 3 µm kidney section, paraffin, P.A.S.M. and H & E, (×1500).

1 µm paraffin, P.A.S.M. and H & E (×2000).

1.5 µm HistoResin, P.A.S.M. and H & E (×1500).

"I never knew it was so easy to improve resolution until I attended an LKB Histology Workshop"

"I'd been a histotechnologist for years when I attended my first LKB workshop. I'd done a lot of routine embedding, sectioning and staining, but I never knew there was so much more to it... let alone what a big difference my work could mean. I thought my paraffin sections were pretty good. My boss had talked about improving quality and mentioned plastics, but I'd heard that they were difficult to prepare, messy and toxic. Did I have a lot to learn!

LKB showed me how to use a new water-soluble plastic embedding system – the HistoResin system. It wasn't difficult at all! I even cut thin serial sections. And what I really liked was seeing that without removing the embedding medium, I could use all the stains I needed – including P.A.P. They also showed me an easy way to cut thin paraffin sections. I cut beautiful 1 micron paraffin sections with the HistoRange microtome."

Why not fill in the coupon below and see for yourself?

I am interested in obtaining more information about:

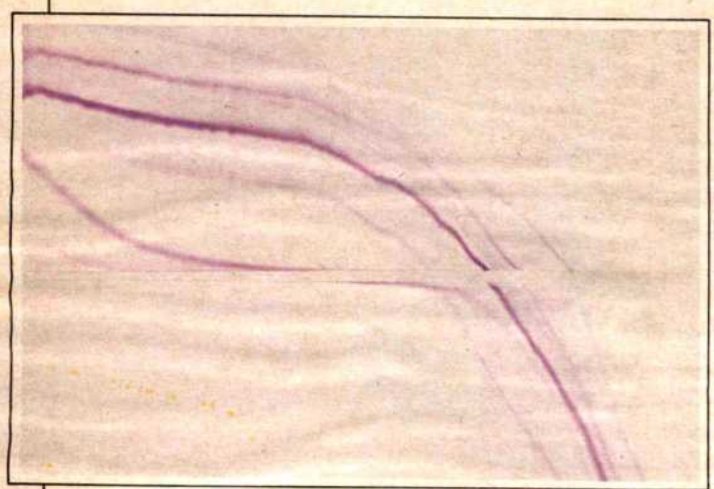
Only with the new LKB Horizontal Electrophoresis System do you also get...



New two-dimensional applications

MAP COMPLEX MIXTURES
LKB's Multiphor II can be used to study complex mixtures by a combination of high performance electrofocusing in the first dimension and ultrathin gradient gel electrophoresis in the second. Used together with newly-developed silver stains, 2-D mapping gives you the ultimate resolution currently obtainable.

2-D electrophoresis of yeast proteins with silver stain (courtesy of Dr A Görg, Technische Universität, München) ▶

Titration curve of carbonic anhydrase (bovine), pH 3.5–9.5 ▼

PREDICT PURIFICATION PARAMETERS
A simple one-hour experiment using the LKB Horizontal Electrophoresis System will produce detailed information about the stability, heterogeneity, interactivity, pI and mobility of your sample. This will allow you to determine in advance the best parameters for optimal purification. The titration curve kit helps you to use the 2-D capabilities of the system to display simultaneously the electrophoretic mobility of every component in the mixture as a function of pH.

This is one in a series of advertisements describing the unrivalled versatility of the LKB Horizontal Electrophoresis System. For further information about 2-D techniques, and the many other applications of the system, send today for our brochure.

THE LKB SYSTEM
Only LKB can offer the research scientist a complete, integrated system in which each component works with and complements all the others. Based on the new and improved Multiphor II, the system also includes a 5KV power supply, thermostatic circulator, laser densitometer and data evaluation software.
In addition to the instrumentation, LKB provides a range of 18 major kits plus a complete programme of high quality chemicals, supplies and accessories, backed by the full worldwide support of the market leader in electrophoresis and electrofocusing.
LKB–the electrophoresis experts.

In immunology, the significant developments come from Coulter.

Coulter's newly-enlarged range of monoclonal antibodies bring significant developments to the surface. Offering human cell surface markers of unparalleled specificity, the range now includes:—

- T/B Cell markers
- Myeloid markers
- Speciality markers
- Immunoglobulins
- Controls
- Developing reagents
- Whole Blood T&B Kit
- Unconjugated or FITC and BIOTIN labelled products.

Post the coupon today, or ring Luton. (0582) 582442 ext. 415, and find out what keeps Coulter at the forefront of immunology research.

No Background Even at 200,000X

Introducing BRL Products for Immunodetection

What you *don't* see is vital in indirect immunological procedures. Background caused by non-specific binding can make your results hard to read, and can even ruin an otherwise successful experiment. BRL's new *flexible system* of *prescreened* Products for Immunodetection, however, is designed to take advantage of the streptavidin-biotin interaction, which ensures specificity, low background and high sensitivity.

See the difference streptavidin makes. BRL's streptavidin conjugates ensure high specificity and low background, even in high-resolution procedures. A superior substitute for egg avidin, streptavidin binds biotin with equally high affinity, but exhibits much lower levels of non-specific binding, producing consistently lower background and clearer results.

Create the system that suits your needs. You can design your detection system—for immunocytochemistry, ELISA, immunoblotting, fluorescent cell sorting or electron microscopy—by purchasing individual components from a selection of five biotinylated secondary antibodies, six streptavidin conjugates and five enzyme substrates. You are assured of optimal results because BRL qualifies all the components for use together.

Rely on the most advanced reagents available. BRL Products for Immunodetection represent the most recent developments in indirect immunological techniques. Streptavidin conjugates include ferritin, colloidal gold, horseradish peroxidase, β-galactosidase, fluorescein and Texas Red™. Enzyme substrates include 4-chloro-1-napthol, diaminobenzidine, o-phenylenediamine, Bluo-gal—a BRL exclusive, and p-nitrophenylphosphate. All five biotinylated secondary antibodies (anti-IgG mouse, rabbit, goat and human and anti-IgM human) are affinity purified, and demonstrate low cross-reactivity against human serum proteins.

Receive all the information you need. Ea product comes with a product profile containing specific information and recommendations for usin in a variety of procedures. In addition, a detai applications guide which describes ELIS immunocytochemistry at the light and EM lev immunofluorescence and immunoblotting, included with every streptavidin conjugate. For questions not answered in the product profile the applications guide, call the BRL Tech-Line™

BRL Products for Immunodetectio Take a look at what you don't see.

New from Amersham

Microsomal membranes for protein processing

Newly synthesized pre-proteins destined for transport across cell membranes can now be processed *in vitro* with Amersham's nuclease-treated canine pancreatic microsomal membranes, code N.270. Our microsomal membrane preparation offers you:

- **Complete reliability:** fully tested for *in vitro* protein processing with rabbit reticulocyte and wheat germ lysates using human placental lactogen mRNA, code N.289.
- **Convenience:** supplied as a preoptimized reagent with detailed, simple and easy-to-use protocols.
- **Total flexibility:** microsomal membranes may be ordered separately or together with our standard HPL mRNA, code N.289, and rabbit reticulocyte lysate, code N.90.
- **Economy:** sufficient reagent is supplied for 50–100 protein processing reactions.

Related products available

- Rabbit reticulocyte lysate, codes N.90/N.150
- Human placental lactogen mRNA, code N.289
- Human placental ribonuclease inhibitor, code N.120
- Amplify™ – fluorographic reagent, code NAMP.100
- Unlabelled amino acid mixtures, codes N.121–N.141
- Amino acids labelled with ^{35}S, ^{3}H, ^{14}C and ^{75}Se

● HOW BRITAIN RUNS ITS SCIENCE

The new edition is available now. Nature's successful wallchart has been updated to take account of the changes in structure and personnel since the previous edition was published in 1981.
It includes the ministerial and other changes which followed the 1983 British General Election and provides a comprehensive survey of the administration of British science. Designed as a fold-out sheet, it can be carried easily to meetings or hung as a poster for permanent reference.

The new wallchart is available at £3.50 or US$7.95 from Nature's offices in Basingstoke or New York.

- IRAS objects
- Defects in non-stoichometry
- Stability of Saturn's rings
- Chlorine isotopic ratios
- Nile chert mine
- Kinked DNA
- Antigenicity of cell cyclin
- Transformation by Epstein–Barr virus
- Chronic effect of nueroleptics

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and, ultimately, for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117, U.S.A.

The conference program has been designed for two groups of people – researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: $85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

MONDAY, 10 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 9:30am — 6:00pm

DAY 1

ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00 — 9:15	**Chairman**
9:15 — 10:00	Oncogenes *R. Weinberg (MIT)*
10:00 — 10:45	Growth factors *M. Spom (NIH)*
11.15 — 12.00	HTLV *R. Gallo (NIH)*
12.00 — 12.30	Clinician's view *S. Broder (NIH)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	The cancer cell *J. Cairns (Harvard)*

TUESDAY, 11 September
Exhibition Viewing: 8:30am — 6:30pm
Recruitment Center: 8:30am — 6:00pm

DAY 2

THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Gene regulation *P. Leder (Harvard)*
10.00 — 10.45	Hereditary cancer *R. White (Utah)*
11.15 — 12.00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12.00 — 12.30	Clinician's view *F. Gilbert (Mt Sinai)*
2.00 — 4.00	Round table with morning speakers
4.30 — 5.30	NCI program

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am — 3:00pm
Recruitment Center: 8:30am — 3:00pm

DAY 3

PROSPECTS AND PROBLEMS — DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9.00 — 9.15	**Chairman**
9.15 — 10.00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10.00 — 10.45	Immunotoxins *J. Uhr (Texas)*
11.15 — 12.00	Drug resistance *A. Varshavsky (MIT)*
12.00 — 12.30	Clinician's view *J. Gutterman (Houston)*
2.00 — 4.00	Round table with morning speakers
4.00 — 4.45	Prospects
4.45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve _____ Conference Registration(s) in the names of: *(Please print or type)*

_____

and _____ Seats at the Tuesday Evening Dinner in the names of:

_____

Name _____ Title _____

Co./Institution _____

Address _____

City, State, Zip _____

I understand that as a paid conference participant, I may attend all sessions, and receive all programs and other materials.

My Check for $_____ is enclosed.
Charge My Credit Card as Shown:
☐ AMEX ☐ VISA ☐ MASTERCARD
Credit Card # _____ Expiration date _____

Signature _____
(as it appears on credit card)
☐ Please Bill Me
☐ Please Bill My Organization

New chance for East-West talks

The Soviet proposals put at Stockholm last week have been too quickly dismissed in the West as an old recipe for arms control. That they may be, but why not talk about them?

THE Soviet decision to pull out of this year's Olympic Games has inevitably overshadowed the Soviet Union's presentation of a string of arms control proposals to the Stockholm conference on European security, which reconvened on 8 May. The first development, ostensibly on the grounds that Soviet athletes would be physically endangered in Los Angeles, is regrettable at such short notice but may in the end be an important contribution to international understanding; the Olympic Games have been, for far too long, occasions for unbridled displays of chauvinism. And on the face of things, the Soviet proposals at Stockholm are both familiar and unacceptable for reasons which by now should be widely understood. Yet that should not prevent the other participants at Stockholm, one of the meetings called within the framework of the Helsinki agreements, from taking this development as an opportunity for revivifying the East–West dialogue on arms control, distinctly in abeyance since the collapse of the nuclear negotiations at Geneva at the end of 1983.

The new Soviet package is a mixed bag of the familiar and unfamiliar. Predictably, it includes (at the head of the list) the demand that nuclear powers should declare that they will not be the first to use nuclear weapons. This old proposal is presumably included for form's sake, since the Soviet Union is well aware that for the past quarter of a century, the defence of Western Europe has been based on the assumption that battlefield nuclear weapons might be necessary to counter a successful conventional incursion from the East. But a no-first-use declaration would also have the contradictory effects of helping to encourage conventional conflicts that could escalate into nuclear wars and of encouraging nuclear powers to keep their nuclear arsenals intact (because of the risks inherent in taking such a declaration at its face value). At Stockholm, however, the Soviet Union has gone further by advocating a treaty under which all European powers would agree not to be the first to use either conventional or nuclear forces. At first sight, this is simply an attempt to revive the old idea of a non-aggression pact between East and West in Europe, a notion which pragmatic Western governments have consistently resisted on the grounds that such an agreement could be only a cosmetic device for pretending that political and ideological differences are less serious than they seem. But in the absence of constructive talks about serious arms control, it would be constructive to know precisely how else the Soviet Union proposes that conflicts should be settled. A standing commission for the discussion of differences of the kind from which European wars could spring would be no bad thing.

Chemical weapons

Freezing (and then reducing) military budgets, another of the Soviet proposals, is by contrast meaningless, pointless and probably unacceptable even in Moscow. Just how powers with international commitments, such as the Soviet Union and the United States, would limit the resources devoted to preparations just for European wars is anybody's guess. Eliminating chemical weapons from the European theatre is, however, a suggestion that deserves serious consideration. None of the governments with interests in Europe can be cheerful about the present need to plan for the use of chemical weapons, and while the chief among them would probably be able deliberately to violate such an agreement (or to counter a violation) within weeks if not days, the risks in being caught napping would not be overwhelming. So there is a case for talking constructively about the central problem in any such proposals — what arrangements could be made for verifying compliance with such an agreement? Technically, as the accusations and counter-accusations of the war between Iran and Iraq have shown, this is an exceedingly difficult issue — which is a good reason why it should be taken up in good time.

The remainder of the Soviet package is still more interesting at least in the sense that discussion can only be fruitful. First, there is a suggestion that the present arrangement under the Helsinki agreements whereby military exercises must be notified in advance should be extended to all movements of troops and military equipment above a scale yet to be fixed. Although intelligence-gathering by both sides in Europe is probably now sufficient for each side accurately to know what the other is about, such an agreement would be well worth having as a demonstration of openness and truthfulness. The West should jump at it.

Zones

The proposal that some consideration should be given to nuclear-free zones in Europe — what many in the West consider to be the most obviously-poisoned chalice in the new Soviet package — also deserves serious consideration, the obvious dangers notwithstanding. Again, more than a quarter of a century has passed since the Polish foreign minister Rapacki proposed that there should be a nuclear-free zone in central Europe (including both Germanies and Poland) agreed only among the governments directly affected. More recently, there has been a great deal of enthusiastic talk in Scandinavia about the potential value of a nuclear-free zone stretching from Finland in the east to Denmark in the west. The Soviet proposal to the Stockholm meeting last week raises the further question of a nuclear-free zone covering the "Balkan peninsula" without specifying whether that term embraces Turkey. All such schemes have the disadvantage that their benefits are much less real than they seem. But although it might lead to nothing, the West should again jump at the chance of such a discussion, if only for its educative value (for both sides).

Of the three proposed nuclear-free zones, that in central Europe is the more important — and more difficult. One almost preliminary difficulty is that of knowing what is meant by the term "nuclear-free". In central Europe, the only possible meaningful interpretation must include the interdiction of the physical presence of nuclear explosives, by whichever organization they are manufactured. (The governments concerned do not manufacture nuclear weapons on their own, but provide house-room for other people's.) Since, in central Europe, it must supposed that nuclear-free territory would quickly reacquire nuclear weapons if hostilities broke out, arguments that apply elsewhere about the propriety of command and control installations are academic. On the other hand, there are serious practical difficulties about the boundaries that might be drawn for a nuclear-free zone, given that an agreement including the whole of West Germany would effectively exclude NATO nuclear weapons from central Europe. Yet both sides would learn a great deal from a discussion of the problems. Why, "without prejudice" as the lawyers say, do they not agree to talk about them? □

Star wars unworkable

President Reagan's best friends should tell him that his star-wars scenario is an illusion.

PRESIDENT Ronald Reagan's plan for a system of "star wars" defences against nuclear attack will not work. The scientific community, which the president asked a little over a year ago to invent the means of rendering nuclear weapons "impotent and obsolete", knows that it will not work, and has said so. The president's advisers, including his science adviser, Dr George Keyworth, know it too, but are afraid to say so. Instead, they have invented a different and more plausible version of what Mr Reagan wants in the hope that nobody will notice the difference. They will of course be found out; the danger is that they might get away with it for long enough to do substantial mischief to the cause of arms control.

Revisionism

The revisionist version of the star wars idea goes something like this: yes, it does seem rather difficult to think of a way to defend the US people against a nuclear attack, but there is no need to look for a near-perfect defence right away. As a first step, the United States might construct a star wars system that could shoot down a fair proportion of Soviet intercontinental ballistic missiles (ICBMs) launched against the United States in a nuclear war. Thus the degree of confidence with which the Soviet Union could launch a preemptive attack on US missiles would diminish; since they would have reason to fear American retaliation, deterrence would be strengthened. Later on, perhaps, the defensive system might enfeeble strategic nuclear weapons so much that they would become too unreliable to be used.

What is wrong with this argument? Plenty, as it happens. But the first thing to say is that it bears virtually no relation to what President Reagan actually said in his star wars speech 14 months ago. In that speech, the president did not propose a defensive system as a means of preserving the ability of the United States to retaliate against a Soviet preemptive strike, but as a way to make retaliation unnecessary. Here is what he said.

> Up until now we have increasingly based our strategy of deterrence upon the threat of retaliation. But what if free people could live secure in the knowledge that their security did not rest upon the threat of instant US retaliation to a Soviet attack; that we could intercept and destroy strategic ballistic missiles before they reached our own soil or that of our allies?

There is nothing ambivalent about that; what the president proposed was a shield through which so few nuclear missiles could leak that the United States would not even have to threaten the Soviet Union with retaliation in the event of a nuclear attack. Is it feasible? Almost certainly not, for reasons that have been fairly and lucidly explained in a new report from the Office of Technology Assessment (OTA). The OTA study is especially significant because it was prepared with the benefit of full access to classified data by a body which is traditionally careful to avoid partisan stances. Even so, it found the prospect of a near-perfect defence "so remote that it should not serve as the basis of public expectation or national policy".

Pessimism

The reasons for pessimism are clear. At least part of a successful defensive array would have to be based in space, where it would itself be hopelessly vulnerable; even if it could somehow be protected, the defensive system would have to shoot at so many boosters, warheads and decoys that its data-processing requirements would be far beyond what is presently imaginable; none of the weapons yet proposed are based on mature technology, whereas countermeasures are; to destroy Soviet missiles before they could deploy their multiple warheads would require such an instant response that a decision to activate the system might have to be taken by machines rather than people.

The biggest flaw, however, is that the principal characteristic of nuclear weapons — the ability of tiny objects to cause massive destruction — continues to make a nonsense of the notion of a "near-perfect" defence. There are, and there always have been, some respectable arguments for defence. After all, the difference between an attack in which 250 megatonnes were detonated over the United States and an attack in which only 5 megatonnes (about one two-thousandth of the Soviet arsenal) got through cannot be ignored. While the former could kill half the population and injure most of the rest, the latter, if cities were preferentially targeted, could kill several million people and injure 10 million more. The scores of millions saved by the successful interception of the 245 megatonnes would have reason to be grateful, but could hardly regard the destruction of the most great cities and the death of millions of their fellows as a near-perfect defence. The temptation to retaliate — and the need to deter — would remain.

So the president's vision of a future in which a leakproof defence makes nuclear weapons obsolete and the threat of retaliation unnecessary is a vision that cannot be given technical expression. The taxpayers of the United States employ people whose job it is to keep the president informed about the limits of technology. Dr Keyworth is one of them. Sadly, there is no evidence that he is willing to give Mr Reagan the bad news; indeed, there are disquieting signs of a witch hunt against those scientists who have spoken out honestly. Some have been accused of defeatism, others of disloyalty. It is, however, an entirely misguided sense of loyalty that has persuaded the revisionists to fudge the issue by arguing that if "star wars" cannot defend everything they can at least defend our ability to retaliate. That is a travesty of the promise President Reagan held out in his speech on 23 March, and an argument that will do him no good politically. Neither Congress nor the general public will be pleased to discover that the panacea in which they have been asked to invest billions of dollars is intended as the strategic equivalent of a hardened silo.

Dishonesty

That is why the revisionist argument is dishonest. But is it wise? There is in general something to be said, as Freeman Dyson argues in his recent book, *Weapons and Hope* (Harper & Row, New York and London), for the moral superiority of defensive weapons. Here the arguments for star wars and for civil defence converge; it is worth trying to save the lives of some even if it is not possible to save the lives of all. The snag is that no policy or action in the domain of nuclear weapons takes place in a vacuum; each increases or diminishes the likelihood of a war being fought with nuclear weapons. There is unfortunately little reason to believe that possession of star wars defences will diminish the likelihood of war, and some reason to believe it will increase it.

That is because neither side, faced with the development of a defensive shield by the other, will acquiesce in the president's aim of making nuclear weapons "impotent and obsolete". Instead, by deploying a defensive shield of impressive but imperfect capabilities, each side gives the other an extra reason to strike first; the shield will be less effective against an unexpected massive first strike than it will against a ragged retaliation by the survivors of an attack. Nor will the shield necessarily save lives. A superpower confronted with a star wars defence could decide to aim a higher proportion of its missiles at cities to preserve its ability to deter. Finally, the development of a star wars system makes the chances of reducing the number of nuclear weapons increasingly remote; if your enemy has a shield you need more arrows.

It is argued by some that even if the defensive notion turns out to be neither feasible nor desirable, there is no harm now in pursuing the research that will keep the United States' options open in the future. The harm, of course, is in allowing the quest for rational progress on arms control to be delayed by the search for technical panaceas; in believing that the next weapon or gadget you invent will make its predecessors redundant. *Vide* Dr Keyworth testifying on star wars research to the Senate Foreign Relations Committee last month: "While I see absolutely no need to violate any provision of existing treaties while we investigate these options, I am very leery of entangling ourselves in future treaties until we know more". □

British Technology Group

Commons committee shows no mercy

A FIERCE attack on the British Technology Group (BTG) was launched this week by the House of Commons Public Accounts Committee (PAC). The chief criticism centres on the investment by the National Enterprise Board (with the National Research Development Corporation one of the two components of BTG) in the company called NEXOS, set up in January 1979 to develop and sell an integrated office automation system. PAC complains that it is "far from satisfied" with the explanation of how the company lost £31 million before it went into receivership in October 1981, and asks that the Department of Trade and Industry should carry out an investigation which "we shall wish to examine".

PAC says it has been hampered in its investigation of the collapse of NEXOS Office Systems Ltd by the fact that the Auditor and Comptroller-General does not have access to the accounts of the National Enterprise Board (NEB). It has, however, been able to establish to its own satisfaction from evidence given by officials that NEXOS, intended to market an office automation system based on word processors, facsimile machines and voice systems, failed because of over-optimistic projections of its sales, "unsatisfactory" relations with component suppliers and "management deficiences".

The PAC report explains that NEXOS when founded was dependent on a commercial agreement with Logica VTS to be the sole source of supply of a word processor which had not been developed when the company first began trading and which was eventually put into production after the date first promised. PAC says that NEXOS "was obliged to purchase, effectively under a cost-plus contract", a word processor over whose development and quality it had no control, and under a contract that did not specify what should happen if "something went wrong".

PAC says that the trading loss reported for the period of NEXOS's existence of £17 million seems "extraordinarily high" by the yardstick of the company's best sales of £8.9 million in 1981, the year in which it collapsed. The committee also asks "whether any consideration was sought in respect of the £5.2 million loss" quoted for research and development and asks why £0.6 million of public money was written off under the heading of "bad debts".

Apart from its particular interest in this investment, PAC emphasizes that the NEXOS collapse is another reason why BTG should be made more directly accountable to the British Parliament. The report is likely to play an important part in the British Government's legislation for a formal merger of NEB and NRDC, which has been planned for the past two years. Evidence given to PAC confirms that the unified organization is likely to function more as a sponsor of innovation along the lines of NRDC than as a source of public money to be used as venture capital, the chief role of NEB in recent years.

PAC is also, however, critical of BTG's handling of INMOS, the company set up in 1976 to manufacture silicon chips in the United Kingdom. Acknowledging that the venture was a "high-risk" undertaking, PAC says it is disappointed that sales forecasts have consistently been unfulfilled but seems even more dismayed that the company's plan to employ 4,000 people by the mid-1980s has not yet been achieved, and that employment at Colorado Springs in the United States is still greater than that in Britain.

The future of BTG will no doubt be clouded by these opinions. The formal merger of the two component organizations apparently waits on parliamentary time (and the government's stomach for the argument it will provoke), but by all accounts BTG has now submitted its corporate plan to the Department of Trade and Industry, on which basis it is likely that the government will outline for BTG the manner in which it will be allowed to continue. One matter still unresolved is the promise, made at the Prime Minister's seminar on technology last September, that NRDC will relinquish its first refusal of innovations arising in the public sector. □

British universities

Tenure principle to be trimmed

THE British Government seems to have hit on the one device for the abolition of tenure in British universities that is likely to satisfy British academics. The Secretary of State for Education and Science, Sir Keith Joseph, announced last week plans to set up a "Statutory Commission" whose function will be to amend university charters to remove from academic contracts of employment explicit references to the expectation that academic appointments will normally continue until "normal retirement age".

The first reactions of university vice-chancellors to the proposal are generally speaking those of people fearful of being about to be hanged who have had their sentences commuted to life imprisonment. For the past four years, the British Government has made no secret of its distaste for the principle of tenure, and two years have passed since the Committee of Vice-Chancellors and Principals put forward proposals for amending the standard conditions of tenure. In particular, the committee suggested that probationary periods for new academics should be lengthened, and raised the possibility of periodic reviews of individuals' performance.

In a letter to the committee last week, Sir Keith Joseph complained that "with one or two limited exceptions, there has been no response" and said that the problem is probably one that the universities cannot "resolve by themselves". His letter also, however, makes plain that the government's objective is that only new contracts should provide for "reasons of redundancy or financial exigency".

The vice-chancellors, who saw the government's letter for the first time at their meeting last Friday, are relieved because the threat of blanket legislation explicitly governing the conditions of academic employment has thus been withdrawn. Even so, the government will have to obtain an Act of Parliament delegating power to legislate to commissioners, whose task will be to rewrite university charters in line with the terms of reference eventually embodied in the act.

Meanwhile, the new development will provide academic lawyers with a rare opportunity for archival work. The proposed statutory commission will be the first since that which, in the early 1920s, arranged to bring the universites of Oxford and Cambridge within the umbrella of public support by giving the central administration of the two universities the right to receive funds from the then new University Grants Commission. Two earlier commissions (in the 1850s and 1870s) had similarly been concerned with the affairs of Oxford and Cambridge.

The enforced reduction of academic staffs in British universities in the past three years appears, so far, to have been accomplished without the principle of tenure being challenged directly. Part of the explanation appears to have been the relatively generous conditions on which it has been possible for academics over the age of 50 to retire early, but it seems clear that the academics' representative organization, the Association of University Teachers, has been anxious to avoid confrontation for fear of having to hazard the principle of tenure.

The universities seem also to have won a victory in their war of attrition with the government by securing an undertaking that a proposed investigation of the efficiency of academic administration, to be conducted at six universities not yet chosen, will not investigate the conduct of academic affairs. This inquiry is likely to be completed in two years. □

Japanese computers

Fifth-generation machines here

Tokyo

JAPAN'S fifth-generation computer project has taken a big step towards its preliminary goals with the successful construction of a prototype relational database machine — the first of its kind.

The fifth-generation computer project aims at the development, by the 1990s, of a completely new form of computer that can communicate in everyday language, "reason intelligently" and bring enormous amounts of stored knowledge to bear on any problem that the user might set it. The machines are intended to be cheap and reliable enough to be used in homes and offices. Some talk as if they will revolutionize society by making freely available a huge fund of expertise that will vastly "amplify human intelligence".

When the project was announced by the Ministry of International Trade and Industry (MITI) in 1981, its sheer boldness and originality astonished people in the West. Japan, considered weak in fundamentally new ideas, seemed overnight to have produced a plan that would give it an unassailable lead in advanced computer technology. One expert even uncharitably described the plan as a "technological *Mein Kampf* ".

Since then, Western governments have responded more rationally with new projects of their own. There are, for example, advanced information technology projects in the United Kingdom, France and West Germany, together with the European Communities' Esprit programme, while the schemes of the United States' Defense Advanced Research Projects Agency were directly inspired by Japan.

The fifth-generation computer will be composed of three main functions: an intelligent interface allowing it to communicate flexibly with humans by speaking, writing or drawing; problem-solving and inference functions allowing problems to be solved by deductive and inductive inference as well as by making sensible guesses where knowledge is incomplete; and a knowledge base function able systematically to store and retrieve not only vast quantities of data but also judgements and test results.

It is within this third function that 45 researchers at the Institute for New Generation Computer Technology (ICOT), set up by MITI to run the project in cooperation with Japan's big eight electronic manufacturers, have now announced a major step forward. Success with the construction of the relational database machine follows by five months the completion of the hardware of one of the other two essential parts of a prototype fifth-generation machine — a sequential inference machine.

The novelty in ICOT's machine is that relational software has been replaced by specially developed hardware. Not all the control software is complete so the machine is not actually doing anything yet. But when in operation, it will be the first true relational database "machine", working two orders of magnitude faster than anything else available. Named Delta, the device consists of two parts: a relational processor complex containing pipelined relational algebra engines (built by Toshiba) and a hierarchical memory subsystem (built by Hitachi), plus an interface (built by Oki). The aim is to be able to connect it with the prototype sequential inference machine by next spring. ICOT hopes then to have two-thirds of a prototype fifth-generation machine, providing the programming environment in which to tackle the really big problems ahead.

Connecting the two together requires that both operate on the chosen "kernel" language of extended PROLOG, the advanced logic programming language invented in France and developed in the United Kingdom. There are several tricky software problems to be solved.

That both ICOT's sequential inference machine, which broke new ground as hardware by allowing extended PROLOG to be used as its machine language (see below), and the relational database centre on relations between things is no accident. ICOT's visionary director, Kazuhiro Fuchi, sees the predicate logic they use, established by Godel in the 1930s, as the key to building knowledge information processing systems. Indeed, he has said that the present generation of computers, based on the Turing theory published in 1936, may one day be seen as a "gigantic historical detour".

The fifth-generation computer project is scheduled to last ten years. The first three years, up to next spring, seem likely to achieve the goal of a prototype machine to be used as a base for further research. Eventually, however, machines will have to work at incomparably greater speeds than at present. The goal is 100 to 1,000 million logical inferences per second (Lips), compared with just 30,000 Lips for the present machine.

This speed can be achieved only by switching to some sort of parallel architecture for the sequential inference machine, probably based on a data flow model (in which the University of Manchester is an acknowledged leader). The project also has to solve the stupendous problems of developing syntactical analysis systems allowing communication with humans in natural language, making a complete revision of PROLOG for parallel use, developing knowledge-base machines utilizing parallel operations and pattern information processing systems.

What has been achieved so far consists of the rapid and determined development of ideas well researched elsewhere. The four-year intermediate stage of the project beginning in 1985, however, requires radical innovations — on time. Those years will decide whether a Japanese fifth-generation computer will emerge in the 1990s or whether it will have to be postponed until the world of information technology is much further advanced.

This year's budget for the project is Y5,100 million (£16 million). Later budgets, it is said, will depend upon "progress in research". **Alun Anderson**

Logic and language for the new generation

RELATIONAL databases are not in themselves new — their mathematical basis was laid out in 1972. What makes them distinct from more conventional data bases, and particularly suits them to "intelligent" applications, is their simplicity of organization. Entries consist purely of relations (essentially two-dimensional tables).

This provides access to any datum in the base either directly or through association and allows data sets to be rearranged in new combinations. If, for example, a set of statistics about university students and their examination results is stored in a relational data base, it is easy to ask the base to provide, say, the names of all students who scored exactly 85 per cent in their examinations. Traditionally, this would be accomplished only by searching through the whole data base. The facility to retrieve data flexibly (by relational algebra) has obvious advantages for intelligent operations, for it will never be clear in advance just how knowledge will be used.

PROLOG, the chosen kernel language, was originally devised for solving problems that involve symbolic representations of objects and relationships between them. To the average programmer, accustomed to writing sequential instructions, PROLOG is something of a surprise.

Thus programmes are written in terms of facts, for example:

```
Tim likes doughnuts
```

written as

```
likes (Tim, doughnuts)
```

rules, for example:

```
Tim likes any object
provided it is sweet
```

and questions, for example:

```
Does Tim like doughnuts?
```

written as:

```
? likes (Tim, doughnuts)
```

which will cause a search to be made to see if a precisely matching declaration can be found in the data. Building from these very simple roots, extremely complex logical arguments can be advanced and complicated inferences be made from one statement to another. Alun Anderson

Nuclear test fallout: 1

US Government arraigned

Washington

A FEDERAL judge in Utah has ruled that fallout from nuclear bomb tests was the "proximate cause" of certain types of cancers developed by nearby residents, and that the government had failed to take proper precautions. Ten plaintiffs, who had developed thyroid cancer, breast cancer or leukaemia, were awarded a total of $2.7 million in damages. All but one of the ten have since died from their illnesses. The judge ruled that another 14 plaintiffs, who developed other forms of cancer, had not proved a link to the fallout.

Although the decision is certain to be appealed by the government, it has given encouragement to thousands of others who are claiming injury from exposure to low-level radiation generated by the government's nuclear programme. These include 375 other residents of southwestern Utah whose cases have not yet come to trail; uranium miners, who say they were not advised of the risks of radiation exposure; workers at the Nevada Test Site; sheep ranchers in Utah who claim their flocks were killed by fallout; and "atomic veterans" who served at Hiroshima and Nagasaki in Japan and at nuclear test sites.

The judge's decision rested heavily on a finding of negligence on the government's part in failing to carry out a proper monitoring programme that could have measured radiation levels in nearby areas and in failing to warn residents to recommend simple precautions. The plaintiffs lived approximately 100 miles from the Nevada Test Site during the 1950s and early 1960s when above-ground nuclear testing was carried out. The plaintiffs were able to sue under a special law that allows findings of negligence against the government in certain cases.

In establishing the nuclear tests as the most likely cause of the cancers, the judge accepted the conclusions of several controversial studies that found higher than normal cancer rates in the region. A 1979 study by Dr Joseph Lyon of the University of Utah, cited in the ruling, found nearly twice the incidence of leukaemia in children exposed to the fallout as compared with children who were born long enough before testing began to escape exposure. That study, however, has been strongly criticized, most recently by Dr Charles Land of the National Cancer Institute; Land argues that the rate of the exposed group is actually no higher than the normal rate of Utah, and suggests that the lower rate of the earlier group may be the result of under-reporting of the disease at a time when that remote part of Utah had relatively poor health services.

The three cancers that the judge said were linked to the nuclear tests are the most sensitive to radiation induction. The plaintiffs received radiation doses of, typically, a few rads. According to several independent experts, these doses — particularly in the case of the leukaemias — are enough to attribute a significant though not overwhelming probability of causation to the nuclear tests. **Stephen Budiansky**

Government veto for Warsaw rector

THE Polish Ministry of Science, Higher Education and Technology has refused to confirm in office the newly elected rector of Warsaw University, Dr Klemens Szaniawski. This decision runs counter to pledges given through the goverment press spokesman, Mr Jerzy Urban, that university officers elected in accordance with the 1982 Higher Education Act would be confirmed in office "with a possible exception". The exception Urban referred to, however, was Dr Janusz Onyszkiewicz, the mathematical logician recently elected to the Warsaw University senate who had been the chief press spokesman of Solidarity. Dr Szaniawski, however, was not even a member of Solidarity.

The swift response from the ministry on Dr Szaniawski is surprising. According to the procedure laid down in the 1982 act, the minister had two weeks to reach a decision. In the matter of Dr Onyszkiewicz's election to the senate (a post far less significant for the running of the university), a stalemate has been allowed to develop. The ministry notified its objection to Onyszkiewicz's election (on the grounds of electoral "improprieties") at the end of March. The outgoing rector, Dr Kazimierz Dobrewolski, said that he was working on his reply and then said he could not act further because he was unclear whether he should convene the old or new senate.

By vetoing the election of the new rector within three days, the ministry has clearly indicated its commitment to the slogan enunciated by Politburo member Tadeusz Porebski, at the plenary meeting of the new Association of Polish Students. The party and state leadership, he said, is "determined to counteract the capture of management posts [in education] by people who do not guarantee the socialist character of the school". Earlier official warnings had said only that the authorities could not tolerate university elections being used to secure a power base for "opposition" elements.

Dr Szaniawski, however, is an essentially moderate figure who, during the Solidarity era, acted as a mediator between the interests of the party and the demands of Solidarity in the drafting of the new higher education and censorship bills. Vera Rich

Nuclear test fallout: 2

Claim and counter-claim

Canberra

THE federal Australian Labor Government is under growing pressure from its own backbenches and the Labor premier of South Australia, Mr John Bannon, to furnish more information about alleged secret nuclear tests at Maralinga in 1963, the allegedly unmarked burial of radioactive equipment and the storage of British tactical nuclear weapons on Australian soil during the 1958–61 partial test ban. It is also alleged that human guinea pig experiments were conducted during the seven official tests at Maralinga in 1956–57. Former civilian and ex-military workers on the test sites have risked prosecution under the Official Secrets Act to come forward with accounts — some anonymous, some in part mutually corroborative — that suggest unacknowledged nuclear test operations. These include stories of badly burned military personnel "berserk with pain", civilian workers told to "climb ladders" or to remain unwittingly in areas five miles away, during the tests carried out in the 1950s, and of fireball and mushroom-cloud explosions observed in 1961.

These claims follow the death-bed allegations by a former Royal Air Force technician, Mr John Burke, that he had found four aborigines dead in a bomb crater after one of three previously undisclosed tests in 1963. His claim to have informed the Commonwealth police of the deaths has provoked charges of an official cover-up, since no record has yet surfaced. Mr Burke died on 1 May of stomach cancer which he believed could be directly attributed to the tests.

Claims by the UK Ministry of Defence (MoD) that the three 1963 implosion trigger experiments were one-ton chemical blasts involving polonium may explain the aborigine deaths, but not, perhaps, the extent of the damage reported in the 1961 blasts, in which steel constructions are said to have been oxidized and lead bricks fused at a distance of one mile. The MoD "confirmation" that the 1963 tests were extremely minor sits uncomfortably with the recently-leaked unexpurgated version of the Pearce report on residual contamination at Maralinga, in which 20 kilograms of plutonium is reported to have been spread over four Maralinga sites during 1956–63, resulting in plutonium plumes of above-tolerance radioactivity extending over thousands of hectares.

The anecdotal eyewitness reports are at present unsubstantiated, but South Australian aborigine leaders say they are planning international court action and Mr Bannon has written to Mrs Margaret Thatcher, the British Prime Minister, and Mr Neil Kinnock, the British Opposition leader, for full disclosure. **Jeffrey Sellar**

Biochemistry in Japan

Applying fundamentals

Tokyo

INCREASED support for fundamental research in the life sciences is planned in a report to Prime Minister Yasuhiro Nakasone by Japan's top science policy-making body, the Council for Science and Technology.

Concern about the long lead of the United States in basic research in molecular biology and the effect this will have on the commercial exploitation of genetic engineering lies behind the report, and swift action is expected on its main recommendations — increasing the numbers and mobility of young researchers and strengthening the technical back-up for biotechnology. But university researchers are likely to be disappointed, for although the report is entirely concerned with "fundamental" research, the government sees this as "essential research fundamental to planned applications". Expansion of truly fundamental research in the universities is unlikely.

To prepare the report, the council, which includes the heads of the science and finance-related ministries and agencies as well as industrial leaders, took special advice from both a life sciences group drawn from government, universities and industry and from a special committee comprising 22 of Japan's leading molecular biologists. Nakasone is expected to accept the report within a few weeks, when the ministries will be expected to work out how it might best be implemented. The financial implications should be included in ministry draft budgets by the end of the year.

Professor Hiuga Saito, head of the Tokyo University's Applied Microbiology Institute, who was the chairman of the council's special committee, stresses that the most important point made by the report is the need to give more young people a training in biotechnology, perhaps by means of special fellowships which would allow young scientists to carry out original research — a possibility already under consideration by the Ministry of Education, Culture and Science (MESC).

The report particularly emphasizes that all three of Japan's research groupings — the universities, government research laboratories and industry — must be encouraged to work together more closely. The idea of a special research institute, supported jointly by government and business, where young people could be trained, is floated. But the university side shows little enthusiasm for that project, and the chances are that it will proceed no further.

A more promising proposal is the removal of restrictions that hamper original research. Increased flexibility is, for example, to be encouraged in the research system so that research proposals not fitting into the conventional "project" funding can find support. Increased freedom for young people to carry out individual research, and increased flexibility in the supply of equipment, perhaps by arranging for the rental of expensive equipment, are other possibilities.

University workers may gain from the recognition in the report that the pace at which biotechnology is advancing means that scientists can stay on top only if they can circulate around top laboratories — increased exchange of researchers is called for, both within Japan and between Japan and foreign countries, including more visits from foreign scientists.

The report also calls for the government to step up efforts to secure the basic resources of biotechnology. Calls are made for the creation of a larger collection of microorganisms, including those with special characteristics and from unique environments, as well as increasing stocks of cell lines, particularly those useful for the creation of hybridomas.

More rapid and thorough dissemination of data, particularly DNA and protein sequences but also data on the special characteristics of organisms and their life cycles, is seen to be important. A new computerized database to complement those existing elsewhere may result. Finally the report argues for the provision of more sophisticated tools for molecular biology — automatic DNA and protein synthesizers and analysers, and microinjection and laser techniques.

If all these measures are put into effect, the result should be a major fillip for research in industry but not for the universities. What the universities lack at present is not money for molecular biology but permanent research staff. An increase in staff (or the new college or department of life sciences that Professor Saito would like to see) is, however, almost impossible under the present administrative system because the government has a long-term commitment to reduce the number of civil servants — and university researchers are civil servants, employed by MESC.

Industry can expect to benefit quickly from an increased flow of researchers and resources. Indeed, confidence that industry can do its own biotechnology research and apply that research with superb efficiency is expressed in a report from a private advisory body, the Japan Economic Research Centre, published after the government council's report. The report predicts that Japan will be the world leader in biotechnology by the end of the century: joint ventures and technical links with foreign companies will bridge the gap over the next three to five years and then Japan's proven ability to commercialize technology should enable it to begin to move into the lead. The only note of caution behind such predictions is the proviso that the universities will have to provide a good supply of trained personnel in search of jobs.

Molecular sequences

UK community seeks access

BRITISH molecular biologists, frustrated by inadequate computing facilities, are attempting to persuade research councils and cancer charities to finance a new national computer link-up and software support scheme for protein and DNA sequencing. Their problems will be aired at a special meeting next month of the Inter-Research Council Coordinating Committee on Biotechnology with interested parties.

The stimulus for the meeting was a letter from prominent researchers addressed to the three research councils that support molecular biology and to the Imperial Cancer Research Fund and the Cancer Research Campaign. The signatories were Dr Michael Ashburner of the University of Cambridge, Professor William Shaw of the University of Leicester and Dr David Glover of Imperial College, London. Their concern arose from a feeling in the research community that scientists have to waste too much time in writing or modifying programmes that are system-dependent. It was also felt there was scope for an improvement in access to databases.

Research council officials are at pains to emphasize that no financial commitment is implied by next month's meeting. Enthusiasts in the research community, however, are already talking fondly of a network of "maybe 6 or 8" VAX machines at national centres, providing regular updates for databases and allowing the transfer of the latest software. These might in turn be connected to microcomputers for local analysis once the letter crunching had been done by the large machines. One estimate puts a price of "one or two million" pounds on the scheme.

The three research councils involved, the Medical Research Council, the Agricultural and Food Research Council (AFRC) and the Science and Engineering Research Council, all have their own budgetary problems. But, it is pointed out, all of these bodies give a high priority to the new biology, and the cancer charities are thought likely to look favourably on the idea. One of the difficulties is that the subject falls between the concerns of several research councils; however, the existence of the inter-research committee, whose chairman is Dr John Ingle of AFRC, has allowed a quick response. And, it is argued, the advantages of a computer link-up have already been demonstrated by the "Starlink" network used by astronomers.

Tim Beardsley

Peace protests

Soviet missiles unwelcome

THE Czech human rights organization, Charter-77, two weeks ago formally repudiated views it alleged had been ascribed to it by the British-based "European Nuclear Disarmament" movement (END). Peace, said the Chartists, is not in itself a sufficient goal — it may mean little more than passivity in the face of tyranny. International peace, they said, can be guaranteed only if governments treat their own citizens with respect. Charter-77 is not a peace movement; there is a "long road" from "the absence of war" to "real peace".

The Chartists' statement seems an overreaction to the current Warsaw Pact propaganda which puts the entire blame for the present nuclear confrontation on the United States. The Czechoslovak people as a whole seem reluctant to accept the official line. Party activists have reported difficulty in convincing factory meetings of the essential difference between "aggressive" United States missiles and their Soviet counterparts now being installed in Czechoslovakia to "defend peace".

Many have signed petitions against Soviet missiles, and students at the Charles University in Prague, aware that signing the petition would almost certainly result in expulsion, devised their own form of protest; a huge placard condemning the Soviet missiles was set up near the entrance to the university, with an invitation to all who agreed with the message to draw a little Sun on it. Within a couple of hours, the whole board was reportedly covered in Suns.

There is now evidence that concern about the Soviet missiles is widespread throughout the bloc. In East Germany, which is also to accommodate the Soviet missiles, there is a well-established "independent" peace movement. This accepts the concept of the bilateral withdrawal of missiles (and later of conventional arms), but is not acceptable to the authorities.

And in both Hungary and Bulgaria, the governments have denied widespread rumours that Soviet missiles may be arriving in the near future. The Bulgarians are particularly incensed, as they are committed to the campaign for a Balkan nuclear-free zone. In Romania (except when Soviet visitors are present), even official spokesmen take the line that they cannot apportion blame, albeit with hints that the West must make the first move. No "unofficial" opinions have so far been reported.

Poland has so far contributed little to the missile debate — save for the usual spate of "spontaneous" condemnations of the West. At least one group, however, has refused to sign such a document (see *Nature* 22 March, p.305). **Vera Rich**

Toxic chemicals

UK guidelines a compromise

BRITAIN's Health and Safety Executive seems to have pleased nobody with its first attempt at British guidelines on occupational exposure to toxic substances, published last week under the unassuming title "Guidance Note EH 40". Some of the concentration limits specified are admitted by industry not be be achievable in the foreseeable future, while trade unions are complaining that the new document weakens their members' legal protection.

Until last week, Britain relied largely on the toxic chemical guidelines produced annually by the American Conference of Government Industrial Hygienists. These were used by factory inspectors to assess compliance with the statutory requirement on employers to ensure their employees' health, safety and welfare "so far as is reasonably practicable". But differences of practice between Britain and the United States, and the conflicting requirements of European Community directives, made home-grown guidelines desirable, and consultations were started in 1980.

The main change is that short-term exposure will in future be assessed over a 10-minute period, rather than (impossibly) instantaneously. This has pleased those who worry about the theory of occupational hygiene, even though, for substances with very rapid effects, the 10-minute principle will have to be ignored. But the numbers in the new list are copied wholesale from the US list it was intended to replace.

These "recommended limits" are "considered to represent good practice" and will be used by factory inspectors "as part of their criteria for assessing compliance". The Health and Safety Executive explains that there are not enough toxicity data on most substances to warrant "control limits", which have been drawn up for fewer than a dozen materials. Control limits for these materials have been set after prolonged haggling between employer and union representatives on the executive's Advisory Committee on Toxic Substances. Embarrassed by the shortness of the list of control limits, executive officials stress that EH 40 will be updated regularly.

Control limits, as distinct from recommended limits, are considered to be "reasonably practicable" and "should not normally be exceeded", according to the executive. But Mr Edward King, an ex-president of the Institute of Occupational Hygienists, says that the existing control limited for lead could not be achieved at any secondary lead smelting factory in Britain in the forseeable future without unrealistic expense. The Chemical Industries Association reluctantly concedes that its members may have difficulty in reaching the supposedly enforceable control limit within 2 years. The limit for acrylonitrile may present similar difficulties.

The Association of Scientific, Technical and Managerial Staffs (ASTMS) condemns EH 40 for being out of date, based as it is on the US list for 1980, which has since been updated. Others think this is no bad thing. ASTMS also complains that it has not been given documentation of the new limits — although there does not seem to be any new scientific work underlying EH 40 and the union is represented on the committee that fixed the limits.

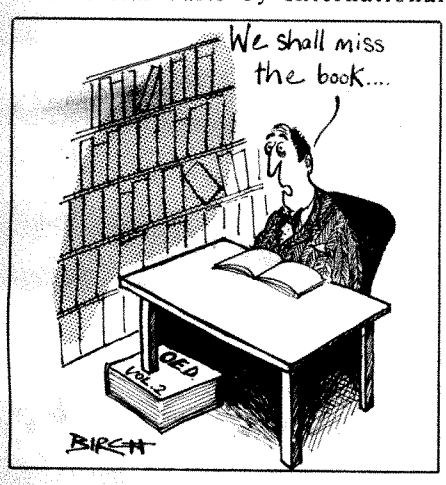
So what is the professional occupational hygienist's considered view of EH 40? Mr King has no hesitation in describing it as window-dressing that will do nothing to improve anyone's health. He believes that most damaging exposure to toxic industrial chemicals now occurs during cleaning and maintenance work, when normal codes of practice are often informally suspended in any case. Real improvements will have to wait until factory inspectors are more numerous or can impose more effective sanctions than at present. **Tim Beardsley**

Modest ecological disaster discussed

Washington

WHAT is fondly known as the "doom and gloom" lobby — the environment and world-future think-tanks that have been warning us for years about overpopulation, deforestation, acid rain, soil erosion and sundry depletions of non-renewable resources — met in Washington last week to say that things are not so bad after all. A conference organized by the World Resources Institute (a new "Center for Policy Research" in the Brookings Institution mould that is also known as the Council-on-Environmental-Quality-in-exile, thanks to the Reagan Administration's efforts to do away with that agency) entitled "The Global Possible" concluded that while the "doom and gloom" scenarios "could be valid", they were "confident that these trends can be reversed". How? By holding the world population to 8,000 million, arranging for a smooth transition to non-fossil fuels, controlling tropical deforestation, avoiding a disruption of global climate, increasing agricultural production, decreasing soil erosion, and, last but not least, strengthening public support for sound resource management.

Among the participants were Russell Train of the World Wildlife Fund, Lester Brown of the Worldwatch Institute, Martin Holdgate of the UK Departments of Environment and Transport and Mihajlo Mesarovic of Case Western Reserve University, a founding member of the Club of Rome. Stephen Budiansky



Computerized dictionary

English language quantified

THE *Oxford English Dictionary*, generally known as the OED, plans to leap into the twentieth century by investing £7 million in the computerized production of a new edition, a merger of the existing 12-volume dictionary with the four-volume supplement still not yet complete. Announcing this plan earlier in the week, Oxford University Press said that the merging of the OED and supplement into a single printed work (to be published in 1988) is merely the first phase of an ambitious programme leading to the availability of the dictionary in an electronic form and eventually to the use of computers for novel lexicographical purposes.

Oxford seems to have been able successfully to turn the respect and affection in which the OED is held into tangible support for the computerization project. IBM (UK) Ltd is lending for the first phase of the project computer hardware (a 4341 processor and up to a score of terminals), software and the services of two specialists on secondment. This assistance, valued at £1 million over the duration of the first phase, compares with the £6.5 million in cash and kind committed in a year by IBM to the support of computer development projects in the United Kingdom.

The Department of Trade and Industry has also provided a grant of £288,750 from its fund called Support for Innovation. The donkey work of "data capture" (or keyboarding) will be carried out on a commercial basis by International

Computaprint of Fort Washington, Pennsylvania.

In preparation for the later phases of the project, Oxford has also made an arrangement with the University of Waterloo, Toronto, Canada, which has undertaken to develop software for the computerized handling of lexicographical data. One obvious possibility is that the dictionary, supplemented by recently accumulated material, will be made available on magnetic tape or by means of a data bank, but there is also a possibility of making the whole work available on optical disks, one of which might be sufficient to contain the 1,000 million characters in the new edition. Oxford will pay a royalty for its use of the software, which the University of Waterloo will be free otherwise to exploit.

For users of the dictionary, the chief disappointment will be that the new edition, to be called the *New Oxford English Dictionary*, will be innocent of the entries accumulated since the appearance of the first supplementary volume nearly twenty years ago. Keyboarding will begin in September this year, but between now and then the dictionary staff will be chiefly concerned to develop the means by which the entries in the OED and the four supplements can be accurately logged and merged, given the variety of typefaces and alphabets used and the need for subjective judgement in telling how supplemental entries supplement the originals.

As things are, the project is cautious about the extent to which the resource being computerized may be used as an automatic source of novel dictionaries, but there seems a good chance that scholars will eventually be able to use the dictionary as a means, for example, of monitoring the rate at which nouns are being converted into adjectives or even verbs. □

Nuclear power

UK peers give Europe advice

THE European Commission should play a stronger role in environmental and energy policy-making, according to a new British report from the House of Lords Select Committee on the European Communities. The committee concludes there is a clear need for an authoritative international assessment of safety and other environmental aspects of nuclear power aimed at reassuring public opinion. It suggests that the commission might join forces with a body such as the International Energy Agency, in order to avoid the appearance of making propaganda.

In the meantime, it suggests that European reliance on the pressurized water reactor could have the "grave disadvantage" that a serious fault or an accident in one of these reactors might cause public opinion to swing against the nuclear energy programme in general. Because of the need to support diverse energy sources, their lordships are concerned to protect and encourage the role of nuclear power, so they suggest that the EEC should give serious consideration to advanced gas-cooled reactors (AGRs) as a possible future design. One of Britain's AGRs, at Hinkley Point in south-west England, is described as "a model of efficiency".

The House of Lords Committee reserves some scornful words for the present policies of the European Commission's Directorate-General XI, which concerns itself with environment, consumer protection and nuclear safety: "Public concern — well-intentioned but not always well-informed — leads to regulatory action before the relevant facts have been established". The Commission directive on sulphur emissions is cited as an example.

The general European objective of reducing oil imports is endorsed, however. The committee sees a danger that lower oil prices at present, which it sees as only temporary, might provide member states with an excuse to delay the move away from dependence on oil. It is also worried by the prospect of greatly increased imports of coal into the EEC, which are thought likely to be necessary in the 1990s. It therefore says that "profitable home production of coal should be encouraged", a delicately-worded statement that might be taken up by either side in the current British miners' strike.

Tim Beardsley

AFRC cuts meet disapproval

BRITISH Members of Parliament have taken up the cause of scientists employed by the Agricultural and Food Research Council who are threatened by redundancy. A report from the House of Commons Agriculture Committee published last week chides the government for imposing on the council cash limits that have forced a programme of contraction.

The committee's predecessor in the last parliament recommended a shift towards more food research, a move since implemented by the council. But the new committee now protests that it was never intended that this should be at the expense of mainstream agricultural research.

The council's submission to the Advisory Board for the Research Councils on scientific opportunities for 1985–86 includes a similar request for more provision for food science without this being at the expense of other work. Plant biotechnology is another area where the council wants to see increased provision.

The government's response to last year's Agriculture Committee report was to propose a new priorities board to advise on the strategy for scientific research related to agriculture, though in the words of Mr Michael Jopling, the Agriculture Minister, "it is expected the advice will usually be followed". But this does not satisfy the Public Accounts Committee, which complains that agricultural research is still "dangerously poised between many pinnacles of bureaucracy". Tim Beardsley

Nuclear war models

SIR — Our study of frost rings as indicators of climatically effective volcanic eruptions (*Nature* **307**, 121; 1984) was discussed by John Maddox in the same issue (p.107) in the context of recent calculations modelling the long-term consequences of nuclear war. We appreciate his synopsis of our study but we do not necessarily agree with his conclusions on the applicability of the frost ring-eruption relationship to the "nuclear winter" question. Mr Maddox emphasized the formation of a frost ring as evidence of a short-lived climatic response to a major eruption and contrasted this seemingly moderate reaction to an atmospheric aerosol veil with the severe picture presented in the nuclear winter scenario, attributing the disparity between the two responses to the nature of the assumptions made about the quantities of dust carried into the stratosphere.

Frost rings are most likely to form at the end of a summer that is already notably or even abnormally cool. Cold delays the completion of cambial activity, rendering the tree more vulnerable to damage by late summer polar-air outbreaks, which occur while the tree is still growing. This suggests not only a short-term regional climatic response, in the form of an unusual incursion of cold air over a period of a few days in years following a major eruption, but also reflects a longer-term response of general cooling — an extreme example of which seems to have occurred in the North-Atlantic sector in the "year without a summer", following the eruption of Tambora in 1815. If a single point source of atmospheric aerosols injected into the stratosphere can have such significant apparent short-term and long-term effects on climate, as well as a characteristic biological response, we believe the implications for the response to global nuclear war are grave indeed.

Nevertheless, the volcano-climate link is appropriate as an analogue for only that portion of the nuclear-war scenario that occurs as a result of large amounts of dust and aerosols reaching the stratosphere . One should indeed expect a large disparity between the respective responses of the climate system to the aftermath of a major volcanic eruption and the aftermath of a global nuclear war, as the former is a reaction to conditions primarily in the lower stratosphere while the latter is likely to be a far more complex response to conditions through several layers of the entire atmosphere, the most important of which is probably cooling due to heavy concentrations of soot and smoke in the mid-troposphere. Mr Maddox seems to have missed the essential point repeatedly made by Turco *et al.* that smoke, because of its high absorption in the visible light range and low absorption in the infra-red, causes most of the surface cooling.

Thus the "Krakatoa effect" — namely, a climatic and biological response to an eruption's aerosol veil — certainly supports the likelihood of a similar effect a nuclear war, but that the volcano-climate relationship alone is not wholly analogous to the far more complex and much more severe climatic and biological responses that Turco *et al.* (*Science* **222**, 1283; 1983), Ehrlich *et al* (*Science* **222**, 1293; 1983) and Covey *et al.* (*Nature* **308**, 21; 1984) have postulated.

● The point of that part of the article complained of was to object that one of the principal references was then still "in preparation" and to assert that predictions of nuclear winter should be regarded as qualitative until more accurate data and calculations are available — Editor, *Nature*.

Lie detector lies

SIR — It is illuminating to express the results of studies in the fallibility of lie detection, such as that of Kleinmutz and Szucko[1], in terms of the amount of information obtained, which can be measured as the "expected weight of evidence" introduced by I.J. Good[2]. Doing so reveals that what is obtained is a small fraction of the information required to take any rational decision.

Expressing experimental results as proportions: valid positive: proportion p of all actual liars, valid negative: proportion q' of all truth-tellers, false positive: $p' = 1 - q'$, false negative: $q = 1 - p$. The expected weight of evidence is the expected value of the logarithm of the Bayes' factor, which is

$$I = p \log (p/p') + q \log (q/q')$$

The logarithms can be taken to any base desired, and I follow Good[2] in using logarithms to base $10^{0.1}$ and calling the result "decibels" (db). Strictly, due allowance should be made for the small sample size, but for illustration I shall use the crude proportions as quoted by Kleinmutz and Szucko, which will tend to overestimate I. The value of I obtained for the results of their six interpreters are 1.3, 0.6, 2.8, 2.1, 0.8, 1.3, averaging 1.5 db (the variation is probably random rather than a reflection of varying skill). This is a very small amount of information. To make a confident decision in normal circumstances we usually need some 20 db — for instance, if we start with a hypothesis at "evens" (50 per cent probability), a log-factor of 20 db, that is a Bayes' factor of 100, will make it 100 to 1 on (99.01 per cent probability), which can perhaps be regarded as "practical certainty". In some proposed applications of the lie detector, however, we are starting with an *a priori* improbable hypothesis — that an apparently honest person is a traitor, for instance. If the prior odds are estimated as 1,000 to 1 against, the log-factor required for practical certainty becomes 50 db.

If some procedure can be devised for collecting many independent scraps of information like this and combining them accurately, for instance by estimating credible log-factors and adding them, it might be possible to produce a reliable result. The "guilty knowledge test"[3] which Kleinmutz and Szucko refer to is an attempt to do this: Lykken suggests using 10 to 16 independent items, which might add up to from 15 to 30 db. Where only the result of a single lie-detector test is available, the "confirmation" that it provides is so small that the only just course is to disregard it entirely.

Crater dated

SIR — The cover of your 19 April issue shows an aerial photograph of Meteor Crater, Arizona. It is stated in the caption that the crater is the "result of an impact about 50 million years ago" but I am unaware of any Meteor Crater age estimates of this magnitude. The crater is clearly of Pleistocene age.

The age of Meteor Crater has been estimated using various lines of reasoning. It was observed 50 years ago that sediments at the crater show evidence of the Wisconsin glacial episode[1]. These soils were later correlated with the well-studied stratigraphy at Hopi Buttes and it was observed that a Pleistocene sediment directly overlies the crater ejecta[2]. Two major pluvial episodes of Pleistocene age are recorded as distinct erosional patterns within the crater[3].

I have recently applied thermoluminescence (TL) dating to shock-metamorphosed sedimentary rocks from Meteor Crater (in preparation). Meteor Crater can be dated by the TL method because the TL of the target rocks was reset by the high temperatures experienced during the meteorite impact. After cooling, TL reaccumulated due to exposure to natural radioactivity. These measurements indicate that the Meteor Crater impact occurred 49,900 years ago with an estimated uncertainty of 2,900 years.

Tropical ecology research

SIR — The table below is compiled from the monthly listings of ecological publications in *Current Advances in Ecological Sciences* between 1979 and 1983. The journal (published by Pergamon, Oxford) cites an annual average of 15,000 recent ecological publications in about 2,000 source journals worldwide, under 56 major categories which I have condensed to 14 topics. The table shows a declining annual trend in tropical ecological research publications from 2.93 per cent of the global total for ecological publications in 1979 to about 1 per cent in 1983. The decline is also evident in each of the 14 areas listed except for tropical ecology (*sensu stricto*).

The major areas of research shown in the table are: (1) plant and animal interaction covering host/parasite relationships, competition and interaction of man and microorganisms (24.2 per cent); (2) plant and animal communities — sociology, population dynamics and behaviour (14.0 per cent); and (3) growth, diseases and adaptation (11.3 per cent). Very little (0.2–2.4 per cent) tropical research work was done in (1) micrometeorology and the use of artificial environments for studying the functions of tropical plants and animals; (2) water relations and hydrology; and (3) the ecology of various tropical plant communities as ecosystems.

The above trends indicate that tropical ecological research has been utilitarian, with emphasis on topics of direct benefit to mankind especially for food production. However, in view of the spread of desertification — which now affects 34 countries in Africa — and the economic crisis caused by the prolonged drought during 1982–83 in more than 24 African countries, including some coastal countries in the wet tropics, I think that much more emphasis should be placed on tropical ecological research dealing with water relations, hydrology and climate.

What is responsible for the decline in tropical ecological research publications? Can it be due to the effects of the economic recession and inflation on research work at universities and governmental institutions in developing countries in the tropics? One trend which has been obvious during the period is the massive migration of seasoned university staff and scientific research workers from the poorer developing countries in Africa to the more affluent developing countries in Africa as well as to the industrialized countries outside the continent. This brain-drain may have contributed to the decline in ecological research work in the tropics; other factors may be the paucity of research funds and facilities, and of the trained middle level manpower needed to support field work.

Classic errors

SIR — R. H. Wright and R. E. D. Cattley (*Nature* **303**, 568; 1983) and M. Macnamara (*Nature* **307**, 590; 1984) discuss the possible meaning of Homer's "wine-dark" sea. Wright and Cattley propose a chemical answer to the problem, suggesting that wine when mixed with the alkaline water of the Peloponnese would turn blue. Macnamara, following W. B. Stanford's observation that the Mediterranean can look wine-red, assumes that the primary question is to account for the redness of the sea, and makes the extraordinary assertion that Homer "mentions only red wine in his epics".

Wright and Cattley have not faced up to the implications of the Ionian origins of Homer and much of Greek culture up to at least the seventh century BC. What happened in the Peloponnese may be irrelevant compared with what happened in Asia Minor.

And (*pace* Macnamara) wine in Homer can be black as well as red. At *Odyssey* 5.265 and 9.196 we meet the phrase *ασκον...μελανος οινοιο*, "a wine-skin of dark (black) wine". Thus "wine-dark sea" may mean a black sea no less than a red sea.

The Homeric adjective *οινοψ* (wine coloured) occurs in the variant forms *οιωψ* in Sophocles and *οινωπος* in other Greek writers. At *Iliad* 18.562 we find *μελανες...βοτρυες*, ("a bunch of black grapes"); similarly, Sophocles (*Oedipus at Colonus* 674-5) applies *οινωψ* to ivy-berries. In fact wine was often described as "sparkling" in Homer (see *Iliad* 1.462 and 4.259), and the particular element of the sea which is important in the Homeric *οινοπα ποντον* is the sparkle of light reflected in the otherwise dark sea. Thus Theophrastus of Straton (*De Coloribus* 2.8) uses *οινωπος* to mean "black mixed with bright light". It may be (as Stanford believes) that *οινοπα ποντον sometimes* refers to a red sea. But this does not have to be the case, and to concentrate exclusively on the redness is to miss the real point. The sea is seen as a dark force, menacing and unpredictable (compare the primary meanings of the verb *πορφυρω* and the adjective *πορφυρεος*), and in this, as in wine, the light and the Sun are reflected (in the words of the poet) "in daggers of bright gold".

Yellow rain — a palynological analysis

Joan W. Nowicke* & Matthew Meselson*

Yellow rain, purported to be an agent of toxin warfare in South-East Asia, contains a high percentage of pollen. Analysis of this pollen in yellow rain samples suggests that they are the faeces of honey bees.

A HIGH pollen content has been reported in samples of yellow rain from South-East Asia[1-7]. We have examined 11 samples of yellow rain allegedly collected at sites of chemical attack in Laos. The samples contain a high proportion of pollen. No two samples, even different spots of yellow rain on the same leaf, have the same composition of pollen types. The plant taxa identified are common in South-East Asia. Seven pollen types in yellow rain samples were also found in *Apis cerana* and honey from Thailand. In general appearance, high pollen content, and differences in pollen composition from one spot to another, the yellow rain samples resemble honey bee faeces.

The first two yellow rain samples we analysed were from small reddish-brown rocks with yellow spots. The third, the ABC News sample, is reported to have been scraped from vegetation by Hmong soldiers in Laos in March 1981 and to contain three trichothecene mycotoxins[8]. The remaining 8 samples were yellow spots from the upper surfaces of narrow lanceolate leaves about 15 cm long. The rocks and leaves were given to Canadian Embassy officials in Thailand in April 1982 by Hmong refugees who said they had collected them at two sites of chemical attack in Laos in March. The records do not specify whether the rock and leaf samples we examined are from one or both sites. All spots were 2–5 mm in diameter, agreeing with earlier descriptions[1,2,7,9]. A 3 mm spot from a leaf weighed 1.5 mg and contained 1.1×10^5 pollen grains. We examined pollen from abdomens of two Asian honey bee species, *A. dorsata and A. cerana*, collected in Thailand by T.D. Seeley, who first suggested that yellow rain samples from South-East Asia might be faeces from cleansing flights of honey bees[7]. We also tested two samples of honey purchased in July 1983 at villages on the Thai-Laotian border, and known faeces of *A. cerana* and *A. dorsata* on leaves collected in July and September, respectively, near Poona, India.

The first rock sample (Table 1, rock 1) was the residue on a piece of paper on which the rocks had been examined. This, and all other samples except as noted were acetolysed before scanning electron microscopy (SEM)[10]. It contained at least six pollen types. None could be confidently identified even to family. The most numerous type, triaperturate and 20–23 μm long, is designated Fagaceae-like. The second sample, rock 2, was from a single spot. Its pollen consisted almost entirely of one of the minor types in rock 1, plus some grass pollen.

The ABC News sample consisted of four yellow fragments of approximately 2 mm^3. SEM of an untreated fragment revealed vague outlines of pollen in an unknown matrix (Fig. 1*a*). Another untreated fragment, mounted in glycerine jelly for light microscopy, appeared to consist mainly of pollen, plus a few bee hairs (setae). The remainder of the sample was acetolysed, revealing about 20 pollen types, some of which are shown in Fig. 1*b, d*. Families identified were Compositae, Dilleniaceae, Elaeocarpaceae, Euphorbiaceae, Icacinaceae, Myrtaceae, Polygalaceae, and Sterculiaceae (Table 1). There was also a small proportion of grains possibly of Melastromataceae/Lythraceae. Grains were found that are indistinguishable from *Dillenia pentagyna* taken from herbarium specimens. Also found (Fig. 1*d*) were grains indistinguishable from those of *D. hookeri*, a species common in Laos[11]. Another type in the ABC News sample (Fig. 1*d*) is indistinguishable from pollen from herbarium specimens of *Macaranga denticulata*, although its rather unspecialized morphology and the existence of some 300 species of *Macaranga* make narrow identification difficult. The most common grain in the ABC News sample is very small, about 10 μm, with three apertures and a smooth/irregularly-pitted surface (Fig. 1*d*). It is classified as Elaeocarpus-like. Also, fungal hyphae and a few setae were seen in acetolysed preparations of the ABC News sample.

Leaf samples 1 and 2 were spots from different leaves, while 3A and 3B were spots a few cm apart on a single leaf, as were the sample pairs 4A/4B and 5A/5B (Table 1). Leaf samples 1 and 2 had three pollen types present in the ABC News sample — *M. denticulata*, Melastomataceae/Lythraceae and a pollen type tentatively placed in *Apodytes* (Icacinaceae). In addition there were hyphae, setae, and stellate, trichome-like structures. An abundant grain in leaf sample 1, probably from Moraceae/Urticaceae (Fig. 1*e*), was not seen in leaf sample 2. Conversely, an abundant grain in leaf sample 2, from *Ilex* (Fig. 1*f*), was not found in leaf sample 1.

Leaf sample 3A contained *M. denticulata, Ilex, Apodytes*, Melastomataceae/Lythraceae and a small proportion possibly of *Nuphar* (Nymphaeaceae). Sample 3B consisted mainly of Fagaceae-like grains, matching those in rock sample 1. The remaining leaf spots 4A, 4B, 5A and 5B, all had *Ilex, M. denticulata, Apodytes* and Melastomataceae/Lythraceae, but in very different propor-

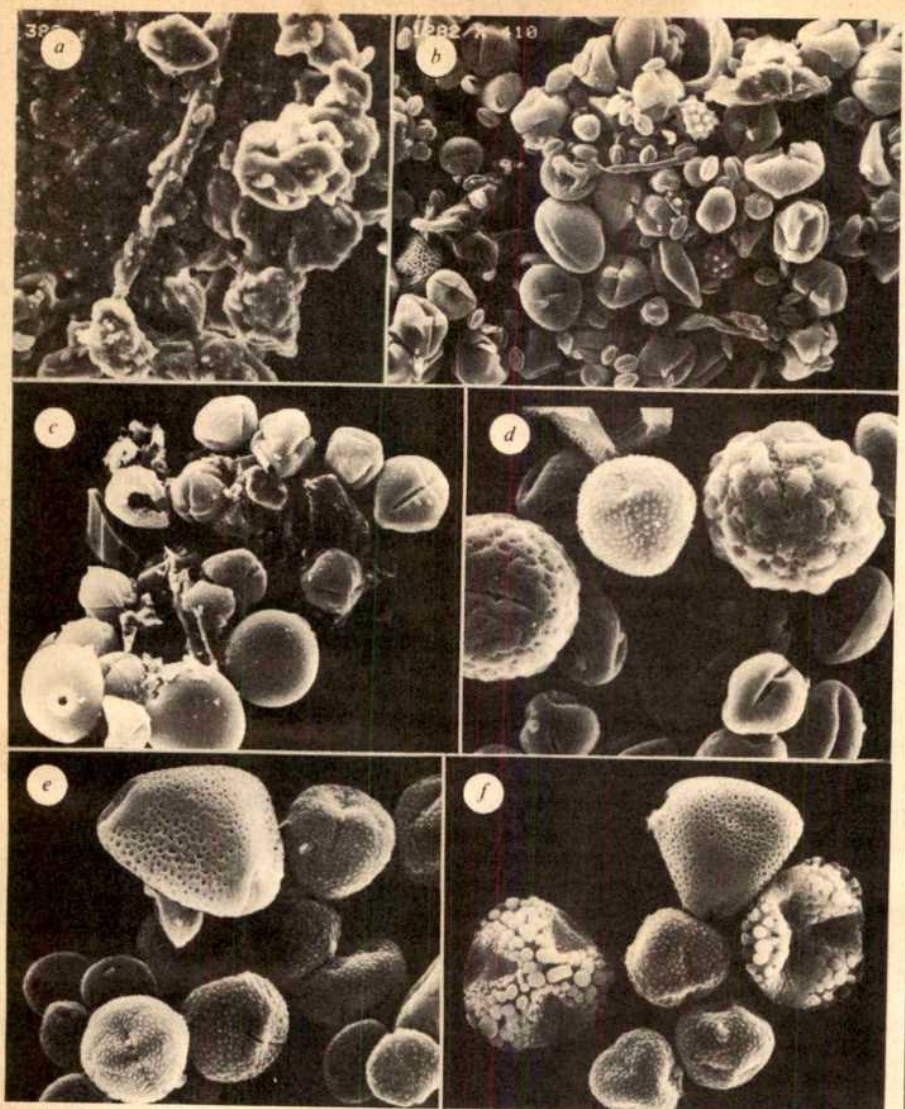

Fig. 1 SEMs of pollen in yellow rain. *a*, ABC news sample, untreated, X250. *b–f*, All acetolysed preparations. *b*, ABC News sample, X270. *c*, Rock sample 2, three spheroidal grains at bottom left are from the grass family, X330. *d*, ABC News sample, larger grain at upper right and partial grain middle left are probably *Dellenia hookeri*; grain between is *Macaranga denticulata*; the triangular grain in background is probably Myrtaceae; numerous smaller gains were classified as Elaeocarpus-like, X1,300. *e*, Leaf sample 1, the largest grain, seen in oblique view is assigned to *Apodytes*; the smallest grains, some showing pores, are Moraceae/Urticaceae; the remaining ones with furrows are *M. denticulata*, X1,170. *f*, Leaf sample 2, the uppermost triangular grain is *Apodytes*, the three small grains are *M. denticulata*, and the remaining two are *Ilex*, the one on the right is partially collapsed, X980.

tions in each case. In addition, 5A had an unidentified type 45–50 μm long, 3–4 aperturate with a thick exine, that was not found in the other samples. The great diversity of the ABC News sample as compared with the leaf and rock samles may be a consequence of collection technique — a number of yellow spots may have been combined.

An abdomen of *Apis cerana* collected in March 1980 contained at least three pollen types: Diospyros-like, a small proportion of grains from the grass family (Gramineae) and a reticulate type 35 μm long, matching in form and range of variation a type in the ABC News sample tentatively assigned to *Sterculia*. *A. dorsata*, collected in March 1980, had pollen probably representing two or three closely related species in *Castanopsis/Lithocarpus* (Fagaceae).

Honey sample 1, from Nakhon Phanom (17° 25′N: 104° 45′E) had at least ten pollen types, but none matched those in the yellow rain samples. Honey sample 2, from Chiang Khan (17° 55′N; 101° 45′E) contained many pollen types including Fagaceae-like, seen in rock sample 1 and leaf sample 3B; the type designated Melastomataceae/Lythraceae, found in the ABC News sample and in leaf samples 1, 2, 3A, 4A, 4B, 5A and 5B; and four more types seen in the ABC sample: *D. pentagyna*, Elaeocarpus-like, and an unidentified four-aperturate grain, 35–38 μm long.

Known faeces of *A. cerana* and *A. dorsata* on leaves collected near Poona, India resembled spots of yellow rain in size, general appearance, high pollen content and the presence of setae and hyphae. Each of three spots of *A. cerana* faeces had at least five pollen types, with only some common to all three. Faeces of *A. dorsata* from a nearby site showed similar diversity from spot to spot.

Our identifications of pollen in yellow rain samples were compared with those in a report from the Australian Defence Department[2]. One of their three samples had mainly Harpullia-like pollen (Sapindaceae); the other two were predominantly Rapanea-like (Myrsinaceae). A Chinese study describes a "yellow rain" phenomenon in September 1976 in Jiangsu[12]. Occurrences generally lasted a few minutes, covering areas of 0.5–20 acres with 2–6mm yellow spots rich in pollen. The authors concluded that the spots were honey bee faeces. Mass cleansing flights of *A. melifera*, causing similar phenomena, have been studied previously[13,14].

All of the plant taxa we identified in samples of yellow rain are common in South-East Asia. The three assignments we made at the species level, *D. hookeri, D. pentagyna* and *M. denticulata*, are trees native only to Southern Asia. Also, a reticulate type in the ABC sample assigned to *Sterculia* was present in *A. cerana* collected in the same season in Thailand. Most significantly, honey sample 2 contained six pollen morphotypes we found in yellow rain, showing that these pollen types are gathered by honey bees in Indochina. No two samples of yellow rain we examined had the same pollen composition; even adjacent spots on the same leaf were different. Pollen diversity from spot to spot was also found for known bee faeces from India. Such differences between spots would not be expected if the spots of yellow rain had been disseminated by an artificial source. Our observations lead us to conclude that the yellow rain samples we examined are probably honey bee faeces.

We thank Diane Baldwin for preparation of the manuscript, Janice Bittner for preparing pollen samples, Joseph Rosen for the ABC News sample, the Government of Canada for rock and leaf samples, George Eickwort for museum specimens of Asian honey bees, Amos Townsend and Dennis Meseroll for honey samples, Fred Dyer for samples of bee faeces from India, Peter Ashton for helpful discussions and Janet Peterson for technical assistance. □

Natural history of yellow rain

The discovery that some of the yellow rain falling from the sky in South-East Asia is the excrement of bees, first dismissed as impropriety, must now be taken seriously.

REPORTS in the past few years that mycotoxins have been used as lethal weapons, in South-East Asia and elsewhere, are not formally disproved by the preceding article which demonstrates that at least some of the yellow-coloured droplets falling from the sky are nothing but the excrement of bees. But they are a serious challenge for those who have been arguing that visual observations of "yellow rain" can all be counted as evidence of the use of chemical weapons against embattled populations, usually of civilians. And because the cause for supposing that yellow rain is proof of the use of mycotoxins against people has not significantly strengthened since the then US Secretary of State Alexander Haig gave it wide currency in a speech in West Berlin three years ago, there is the strongest possible reason why the scraps of evidence which survive should be looked at again, and reassessed.

Reports of the use of chemical agents against people in South-East Asia, principally in Laos and Cambodia (now Kampuchea) have been current since the late 1970s. By the time the United Nations set up a committee to investigate the allegations, towards the end of the General Assembly in 1980, there was a great mass of untested anecdotal evidence, usually gathered from the verbal reports of refugees from the endemic conflict in that part of the world. Many people from villages in the region reported having suffered from rashes, pulmonary and bronchial trouble and fevers after materials of various kinds and colours (black, blue, red, yellow) had been sprayed from the sky by aircraft. Many reported that fellow-villagers had died.

The report of the UN expert committee, which appeared in November 1981, served principally to show how difficult a task it had been given. Permission to visit the areas concerned was never forthcoming, with the result that evidence had to be collected from people already in refugee camps in Thailand and thus unable to point to the places in which supposed toxins had fallen from the sky. The UN expert group confesses in its report that the language problem was a serious impediment to straightforward investigation. While many of the reports thus gathered referred to fatalities in the aftermath of aerial spraying, with other people falling sick, deaths seem never to have been so numerous as to suggest an effective military weapon in the form of a toxic agent.

The suggestion that mycotoxins, toxic materials produced by the metabolism of certain fungal species, might be involved first appeared in a paper issued in Washington by the State Department in the wake of Secretary Haig's Berlin speech, announcing that evidence pointing to the use of toxic agents had been acquired. The identification on the surfaces of leaves smuggled out of South-East Asia of small quantities of trichothecene mycotoxins of a kind produced by species of the fungi *Fusarium* was a considerable triumph for chemists, and for Dr C.J Mirocha in particular. There is no reason to suppose that the measurements are in any way in error, but the manner in which the samples were collected (without controls), and the presumption that "yellow rain" was indeed the vehicle by which mycotoxins had been delivered, is bound to cast doubt on the interpretation of this scanty evidence.

It tends to be forgotten that the investigation of these obscure materials, mostly sesquiterpenes, is not much older than the suggestion that they have been used against human populations. Although it is in retrospect clear that human disease caused by trichothecenes was known to Galen, and while toxic epidemics caused by contaminated grain were common in the Soviet Union in the closing years of the Second World War (and have since been known in the United States, Mexico and India), identifications of chemical structures have all been crammed into the past fifteen years. Analytical techniques, among which the most sensitive are those based on immunological methods, can at their most sensitive detect nanogram quantities. Monoclonal antibodies may bring further improvements.

Pinning down what has been happening in South-East Asia will not be easy, especially if the presumption is correct that mycotoxins have been used in warfare — and if those responsible have changed their ways with all the publicity there has been. The most recent sober assessment of the trichothecene problem, the report *Protection against trichothecene mycotoxins* published towards the end of last year by the National Research Council in Washington (and primarily concerned with the civilian agricultural problem), points out that the symptoms of disease and death reported from South-East Asia are in many ways similar to those experienced by laboratory animals and the handfuls of terminal patients to whom the materials are reported to have been administered. But the report also says that the symptoms are not identical, which may be explained by a mixture of several related mycotoxins as might be expected in natural conditions — or by a quite different cause.

What seems, however, unambiguously to follow from what Nowicke and Meselson have to say is that the association of physical damage to people in South-East Asia can no longer be simply linked with yellow rain. At least some of that consists of bees' excrement, and for the time being there is no evidence that that is associated with mycotoxins. If it were, of course, the suggestion that toxic agents of some kind have been used against people in South-East Asia would be further undermined. But now it seems more prudent that those concerned with investigating the several possibilities should go back to the beginning, and consider other ways in which mycotoxins might have been delivered.

Hitherto, serious questions on these points have been met, at the State Department and at analogous departments of government elsewhere, with the statement that while the publicly available evidence that yellow rain is a shower of pollen doped with toxin so as to make its ingestion more probable may be slight, there is no publicly available evidence that the facts are what they have been said to be. The assumption, indeed the assertion, is that intelligence services know to be a fact what seems in the public world to be improbable. Such arguments nonplus.

For all of us, the best and simplest solution may be that the association between yellow rain and the injury or death of people in South-East Asia should cease to be a lively issue, perhaps as a consequence of climatic or ecological good luck — or perhaps, if people have been using toxic materials in the area, because they change their ways. But since luck is as often bad as good, the only constructive way forward must rely on a thorough investigation of the natural history of yellow rain in South-East Asia, and of the reported association of injury and ill-health among people.

While the State Department has unfairly dragged into a confusing argument evidence that it cannot publish, the governments directly concerned have nothing to lose by letting people investigate what has been happening.

John Maddox

Human evolution

A gathering of our ancestors

from Bernard Wood

THE word 'unique' is abused by us all, but is aptly applied to the 'Ancestors' programme mounted this year by the American Museum of Natural History (AMNH) in New York. Readers will doubtless be aware of the recent resurgence of the creationist movement and its attempts to influence both public opinion and, more importantly, the views of legislators. Scientists have counter-attacked in print but large organizations and institutions have, as always, found it more difficult to respond effectively to what amounts to an attack on the foundations of all scientific endeavour — namely, reason and evidence. The AMNH has not, however, been idle. Three of its curators, John Van Couvering, Eric Delson and Ian Tattersall, conceived the notion of an exhibit of original fossils which would show the public the evidence which enables palaeoanthropologists to trace the path, or paths, that have led to modern humanity. With the endorsement of UNESCO, the museum set about the task of persuading governments, museums and curators to loan their precious fossils. The excellent response — a tribute to the competence and tenacity of the organizers — has produced a spectacular exhibition, which opened to the public on 12 April and will run until September this year.

The designers have sensibly allowed the fossils to tell their own story. The legends are informative, authoritative, but concise, and the fossils have been displayed in a way that allows visitors to see and understand these remarkable documents of our past. Where important specimens were not made available, the organizers have made sensible use of casts to illustrate them. While one can understand the reluctance of curators to part with their fossils on the grounds of security, it is disappointing, but perhaps inevitable, that political considerations should have prevented the display of some material which is supranational in both its scientific importance and its social significance. There are no 'stars' in the exhibit, and all who see it will be impressed, perhaps moved, by different aspects.

What impressed me most were the specimens from the two ends of the time span: the early fossils from the Oligocene and the Miocene, and the late Neanderthals. The enigmatic cat-like skull of *Aegyptopithecus* and the face of *Sivapithecus* are mercifully unaware of how closely their every fissure and prominence is being analysed to seek evidence of affinities. The Neanderthals impress because, despite differences in size and geographical location, they all really do show the characteristic features of the face and vault. They are convincing evidence that morphologists can detect reliable marker features despite the potentially confusing background of intraspecific variation.

Although it is a major part, the exhibit is only one of three components of the Ancestors programme. The two others, a series of study sessions and a five-day symposium entitled 'Palaeoanthropology: the hard evidence', were held last month, and were sponsored by the AMNH with the support of the NSF and the Wenner-Gren and Leakey Foundations. Each study session provided an opportunity for the close study of five or six of the original fossils by as many palaeontologists. My original scepticism of the usefulness of such a scheme was, in large measure, unwarranted. In particular, the sessions made it possible to discuss points of interpretation with those who were expert either on particular anatomical regions, for example Y. Rak (Tel Aviv University) on the face, J. Laitman (Mt Sinai School of Medicine, New York) and W. Kimbel (Cleveland Museum of Natural History) on the cranial base and F. Grine (SUNY, Stonybrook) on the teeth, or on particular remains, such as R. Clarke (University of Witswatersrand) on SK 847 from Swartkrans and Stw 53 from Sterkfontein. These were truly workshops, and ideas were exchanged and debated in a spirit of collaboration which bodes well for future research.

A symposium which attempts a comprehensive review of hominid evolution from the Oligocene to the Holocene is too broad in its scope usefully to address any particular research problem, but three strands could be traced through the five days. The first was the quality and breadth of information about the temporal and palaeoenvironmental context of hominoid and hominid evolution. The second was the increased and welcome emphasis on studying variation within an anatomical region, across a wide range of fossil and extant forms, and the last was the increasing influence of phylogenetic analytical methods on hominid palaeontology.

Reports of research undertaken in the Potwar Plateau (D. Pilbeam, Harvard University), at Laetoli (reported by J. Harris, Los Angeles County Museum), in the Omo Basin (F. Brown, University of Utah) and at the South African Cave sites (C. K. Brain and E. Vrba, Transvaal Museum) served to emphasize the importance of the contrasting, but complementary, contributions of the physical sciences and faunal analysis to evolutionary studies. Brown reported a combination of chemical and microscopic analysis which has demonstrated that an ash widespread in the Omo Basin is present in deep-sea cores taken from the Gulf of Aden. This is compelling evidence in support of the contention that the same ash is present at Hadar (which has been effectively leap-frogged by the marine sediment evidence) and is a powerful illustration of the potential of such techniques. H. Thomas and E. Vrba made thoughtful and impressive use of faunal evidence in their contributions. Thomas reviewed the evidence for two phases of Neogene dispersal across the land bridge(s) between Africa and Asia: one at about 18×10^6 BP and the other at 15×10^6 BP. Vrba urged hominid palaeontologists to see hominids in the context of evolutionary changes occurring in other groups of land mammals. She associated, if not correlated, the marked peak in the rate of appearance of bovid species, and probably other groups as well, with a major change in climate. The apparent appearance at this time of *Homo habilis* and the 'robust' australopithecines suggests that hominids may have reacted in a similar, but more modest, way. It is therefore of some interest that at least one hominid palaeontologist suggested that the early phases of the evolution of *Homo* may have been more complex than usually presented. Vrba's admirable attempts to suggest a scenario for hominid evolution are, like many others, heavily influenced by the assumption that the hominids in Members 4 and 5 from Sterkfontein are taxonomically distinct, but more evidence will be needed before Stw 53, from Member 5, can be confidently included in *Homo habilis*.

There was evidence among some hominid palaeontologists of a move towards considering whether features are widely or narrowly distributed, and utilizing this, and additional, information to deduce morphoclines and thus clade groupings. But the shift towards this philosophy was stoutly resisted by others. Grade and clade arrangements rest on different premises. It is therefore pointless arguing about palaeontological details when at the heart of differences in interpretation are deeper philosophical divisions. Hominid palaeontology must, like other branches of palaeontology, see that its scientific dialogue is adjusted to take account of this. Cladists have to realize that a cladogram based on a narrow range of features stands an even chance of being unreliable when seen against the background of a comprehensive set of character states. Adherents of the classic 'Simpsonian' approach should also be aware that a concept such as the 'total morphological pattern' is often couched in such a general way that any systematic decisions based on it are essentially untestable. □

Bernard Wood is Professor of Anatomy in the Department of Anatomy and Biology as applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DP.

Cell biology

Epidermal growth factor receptor—yet another domain?

from Shelley Earp

CELLS responsive to epidermal growth factor (EGF) carry specific receptors for EGF on their surface membrane. Between 12 and 24 hours after EGF binds to these receptors, the cells begin to synthesize DNA. In the meantime, the majority of the EGF–receptor complexes have been removed from the cell surface by a process of internalization into cellular vesicles[1,2]. A long-standing question has been whether the cellular events triggered by EGF are solely a consequence of intracellular messages generated at the cell surface by ligand–receptor binding or whether the internalized complex can have additional intracellular functions. A radical re-examination of this question will be forced by the paper on page 270 of this issue of *Nature* in which Mroczkowski, Mosig and Cohen suggest that the EGF receptor has a direct effect on the structure of DNA[3].

The suggestion stems from the authors' detection of an endonuclease activity in preparations of EGF receptor highly purified by affinity chromatography. The activity is specific for the nicking of double-standed circular DNA and is stimulated by ATP but not by a non-hydrolysable ATP analogue. In those respects it resembles the enzyme DNA topoisomerase II but it has not been possible to demonstrate for the EGF receptor the DNA circle-closing activity characteristic of topoisomerase II[4].

The authors' interest in the latter enzyme, which catalyses topological rearrangements of DNA that are thought to be important in the regulation of transcription and replication[5], may stem from several reports that relate EGF receptor and topoisomerases. First, EGF increases DNA topoisomerase II activity in human foreskin fibroblasts[6] and this activity is also increased during liver regeneration[7], when EGF receptor internalization is known to occur[8]. Second, Wang and colleagues have shown that topoisomerases are covalently bound to the 5′ end of nicked DNA through a phosphotyrosine linkage[9]; the EGF receptor is well known to have tyrosine-specific protein kinase activity and to autophosphorylate its own tyrosine residues. While it is difficult to envisage the same catalytic site both transferring phosphate and forming protein–DNA linkages, the autophosphorylation site on the receptor could also serve as a topoisomerase-binding site.

As the authors point out, an important unresolved question is whether the endonuclease activity of the receptor preparation is the result of a contaminating enzyme detected by a highly sensitive assay. The concentration of receptor used is higher than would be necessary to detect receptor autophosphorylation. Most assays were conducted with 4–16 molecules of receptor per DNA circle and the limit of detection of endonuclease activity was 0.4 molecules per circle. The poor catalytic activity could be due to loss of activity during purification but the nuclease seems to be more stable towards heat denaturation than the receptor's tyrosine-specific protein kinase activity.

The dissociation of nuclease and kinase activity is troubling in another sense. Mroczkowski *et al.* indicate that purified pp60^{src}, the product of the transforming gene of Rous sarcoma virus, has an endonuclease activity similar to that of the EGF receptor. Both pp60^{src} and the EGF receptor exhibit tyrosine-specific kinase activity. If the endonuclease and kinase activities can be dissociated one might expect to see two distinct regions of sequence similarity between pp60^{src} and the EGF receptor. And yet the two proteins seem only to be related by sequence in the kinase domain[10].

Another nucleotide-binding site on the receptor would also need to be invoked to explain the differences in nucleotide specificity of the kinase and endonuclease activities of the EGF receptor — for example, GTP can be used by the former but not latter[11]. The nucleotide specificity of the reported endonuclease activity also differs from that of topoisomerases which, at equivalent concentrations of enzyme and DNA, can be stimulated by non-hydrolysable analogues of ATP[12].

Given there is little doubt that receptor occupancy causes immediate alterations in membrane function, probably related to stimulation of the receptor's protein kinase acting through tyrosine phosphorylation of perimembrane substrates, autophosphorylation of aggregated EGF receptors, or, as recently proposed, through phosphorylation of phosphatidylinositol[13,14], does the endonuclease activity of the EGF receptor have biological relevance? If it has, receptor internalization must be a prerequisite for EGF action. After a decade of research, the necessity of internalization for the mitogenic response of cells to EGF has not been established — but neither has it been ruled out. So it is worth considering several potentially relevant points about the consequences of internalization.

Since the EGF receptor has been shown to be proteolytically processed upon internalization[15], one possibility is that the process yields a new structure that dictates its own translocation to a specific site of action, such as the nucleus. If the translocated fragment acts catalytically only a small portion of internalized receptor would need to be segregated to the nucleus to produce a biological effect. It may also be of relevance that proteolysis seems to increase the activity and alter the topological specificity of certain nucleases[16]. Perhaps the EGF receptor is a pronuclease whose activity and catalytic repertoire can be increased by proteolysis. If proteolytic activation simultaneously eliminated the binding and antigenic domains of the receptor that are external to the cell surface, the fact that neither EGF binding nor receptor immunofluorescence has been consistently observed in the nucleus could be explained. If the catalytic endonuclease moiety generated by proteolysis had a short half life, it would account for the need to terminate the function it served after an appropriately short time. Any hypothesis that EGF releases a latent endonuclease activity must take into account the fact that EGF does not cause growth in all receptor-bearing cells, that EGF binding and action are influenced by other humoral agents and that in some cells the need for EGF can be abrogated by combinations of other factors[17-20]. It is possible that an endonuclease domain could be processed differentially depending on the cell type or the influence of modulating factors, but would cells opt for another level of complexity in their growth control network?

Several questions raised by the provocative findings of Mroczkowski *et al.* should quickly be resolved. Can the EGF receptor form a phosphotyrosine linkage with DNA? Can conditions be found to express the topoisomerase II-like circle-closing activity? Does experimental proteolytic cleavage of the receptor produce a receptor fragment with greater or more definable endonuclease activity? Is the ATP-stimulated DNA-nicking an intrinsic activity of the EGF receptor or will

a contaminating nuclease be separated from receptor preparations? Cohen has been consistently linked with new advances in the field of growth factors. His pioneering efforts in identifying and purifying EGF and its receptor have led to the discoveries that have set the rest of us in new directions. The new data from his laboratory direct attention to the nuclear effects of EGF and will undoubtedly stimulate discussion and experimentation. However before clamouring to exchange acrylamide for agarose, cell biologists should await further developments. □

Retinitis pigmentosa

Progress in sight

from Miranda Robertson

THERE is no doubt that molecular genetic technology is leading to an understanding of human genetic disease at a depth and resolution inaccessible to more traditional methods. Because the path to that understanding is often indirect, however, for the time being it presents a problem for clinicians as well as a challenge for research scientists. This is inevitable when the gene defect underlying the disease is unknown, and can be approached only through linked genetic markers. Such is the case in Duchenne muscular dystrophy, for which a marker was first reported two years ago[1], and Huntington's disease, for which a marker was discovered last last year[2]. On page 253 of this issue of *Nature*, Bhattacharya, Wright and their colleagues report an exactly similar marker for the X-linked form of retinitis pigmentosa[3].

As with Duchenne and Huntington's, the retinitis pigmentosa marker is simply an identifiable fragment of DNA that is close enough to the gene to be inherited with it, putting molecular biologists within 'walking' distance of the defective gene itself and offering clinicians the prospect of identifying some symptomless carriers of the gene and, possibly, diagnosing their unborn babies. What are the obstacles confronting the research biologists and the problems facing the clinicians?

Retinitis pigmentosa is the name given to a genetically and phenotypically heterogeneous group of degenerative diseases of the photoreceptor cells of the retina leading, in severe cases, to blindness. The mode of inheritance can be recessive, autosomal dominant or X-linked. The X-linked form, for which Bhattacharya *et al.* now have a marker, is one of the most severe; it accounts for perhaps 30 per cent of all cases and affects about 1 in 20,000 of the population. Because the defective gene is on the X chromosome, of which males have only one, they have no normal gene to compensate for its effects and are severely affected, often in childhood. Females, with two X chromosomes, may have a mild form of the disease or none at all; but they risk transmitting the severe form to their sons. Female carriers of the gene, and the daughters of known carriers, who have no way of knowing whether they themselves are carriers, stand to gain most from the new marker. But it will not help them all, for reasons that follow from the nature of linked markers in general.

The marker in this case is a DNA probe designated L1.28, corresponding to a small fragment of the human X chromosome. What allows this fragment to be used as a marker is its polymorphism — which is to say that it contains minor variations that can be detected by bacterial restriction enzymes (for a slightly fuller explanation of how this works, see ref. 4). L1.28 has two distinguishable variants, A1 and A2. Bhattacharya *et al.* were able to establish the linkage of L1.28 with the retinitis pigmentosa gene on the X chromosome by tracing the inheritance of both the disease and the A1 and A2 variants through five different families.

In the case of close linkage, you would expect the disease to be inherited consistently with one or other of the two variants within a given family; and this is what Bhattacharya *et al.* found. In four families retinitis pigmentosa was consistently inherited with A2; in the other one it was associated with A1. It is just possible that more than one gene on the X chromosome can give rise to retinitis pigmentosa. If so, the linkage will break down in further family studies. So for the time being clinical advice will not be offered on the basis of the L1.28 marker.

But assuming, as seems most likely, that there is only one gene, what are the limitations of L1.28? Most obviously, an affected male relative must be available to establish whether the defective gene is associated with A1 or A2 in the family in question. The second important limitation arises from the fact that both A1 and A2 are present at high frequency in the normal population. Take the case of a young woman whose father has the disease. Since one of her two X chromosomes must be her father's, and his single X chromosome has the defective gene, she will be an obligate carrier and there is an even chance that any son born to her will inherit retinitis pigmentosa. As things stand, she would be offered termination of any pregnancy in which the fetus was male — the entire X chromosome serving as a crude and unreliable marker for the disease. The L1.28 marker makes it possible to distinguish fetuses bearing the normal X chromosome of the mother from those bearing the defective one — but only if the mother is heterozygous for the marker: that is, if she has A1 on one of her X chromosomes and A2 on the other. In that case, if her father's X chromosome bears the A1 variant she can be certain that any male fetus inheriting A1 will also inherit retinitis pigmentosa, and conversely if he inherits A2 he will be normal. But if she is homozygous — that is, she has A1 on both X chromosomes — there is no way of distinguishing a normal male from an affected one before birth. Given the frequency of the two variants in the general population, only 40 per cent of women will be heterozygous.

Similar considerations complicate the case of a woman for whom the family history of retinitis pigmentosa is on her mother's side. Because the symptoms of the disease in women develop late or never, she may not know even whether she is a carrier. If her mother is homozygous for the marker, the marker cannot enable her to find out; though it may, if she herself is heterozygous, enable the disease to be ruled out in some of her unborn sons.

Finally, even for a heterozygote, there is always the slight chance (decreasing with the closeness of the linkage) of misdiagnosis if the defective gene has become separated from the linked marker by genetic recombination. The identification of a second linked marker, on the other side of the gene, would dramatically reduce the probability of mistaken diagnosis; it would also be helpful in the pursuit of the retinitis pigmentosa gene itself.

This, of course, is the longer-term aim of the research: in the end the only entirely reliable genetic probe is the one that identifies the mutant gene. Progress will demand patience and ingenuity. Patience because the distance between L1.28 and the retinitis pigmentosa gene is something on the order of 3 million bases; so to reach the immediate vicinity of the gene will require either a marathon chromosome walk or laborious family studies to find more closely linked markers; and ingenuity to identify the gene once it has been isolated. For retinitis pigmentosa, the best bet may be to compare the genes expressed in normal retinas with those expressed in affected retinas, by means of cDNA libraries from the two tissues.

How soon might a gene probe for X-linked retinitis pigmentosa be available? Should female carriers or suspected carriers wait a year or two before starting families in the hope of reliable prenatal diagnosis? In the case of Duchenne muscular dystrophy, there is still no gene probe two years after the first marker; but optimists expect one this year. □

Archaeology

The decline of Rome to a fast-food empire

from Richard Hodges

A NUMBER of recent archaeological publications provide evidence of a socio-economic transition that occurred in the Roman Empire as it declined and fell — 'the greatest, perhaps the most awful scene in the history of mankind', according to Edward Gibbon[1].

Whereas Gibbon's analysis of the faltering empire did not include such a transition, it had been anticipated by Henri Pirenne in his famous book *Mohammed and Charlemagne*, published half a century ago, the theme of which was returned to last year by C. R. Whittaker[2] who argued the revolutionary hypothesis that increased state exactions in kind in the later empire, and the effective decommercialization of the economy, reflected a reorganization of the means of exchange rather than economic decline. There was no fall, he contends, in production or exchange, only a decline in the entrepreneurial commodity market[3]. This reorganization, he argues, forms the foundation on which the medieval economy was constructed. But with such patchy documentation to support his argument, Whittaker, like Pirenne before him, is unable to measure change in production or distribution with any precision.

Archaeological evidence alone will adjudicate on this issue[4], and a recent volume of archaeological surveys in the Mediterranean area[5] pointedly illustrates one aspect of Whittaker's thesis. There was undeniably a change in the organization of production in the countryside towards the end of the fourth century AD; far fewer sites are characterized by the highly distinctive African Red Slip wares of the fifth and sixth centuries in all parts of the Mediterranean basin. Sadly, though, little attention is drawn to this fact — an occasion where archaeological statistics appear to be meaningful[6]. But what exactly does this reorganized rural pattern mean?

Alistair Small has excavated a Roman villa at San Giovanni di Ruoti in Basilicata that appears to be typical of the later Roman settlement system in Italy[7]. By early Roman standards it is a modest affair, but Small contends it is a normal residence of a *dominus*, a landlord in the fifth to sixth century. Of particular interest are the faunal and ceramic assemblages from the middens around the villa. As many as 40 per cent of the bones in the early fifth-century midden and 65 per cent in the later fifth-century midden are from pigs. The traditional balanced blend of meat consumption and stock-rearing on rural estates seems to have been abandoned in favour of the short-term fast production of pork. A passion for chops became the fashion of the time. However, while the animal bones reveal a trend towards fast-food processing, the pottery assemblage confirms the persistence, albeit in a re-organized form, of regional production–distribution services for ceramics. Several of the contributors to the volume in which Small's essay appears note the distinctive character of the later Roman economy as the state's role begins to diminish at a regional level.

Related information comes from the first part of David Whitehouse's important excavations at the foot of the Palatine[8]. From a study of the animal bones found there, Graeme Barker concludes that about 40 per cent of the meat eaten at this site was pork — a finding which he argues may be illuminated by the Theodosian code (AD 438) which describes guilds of pork suppliers who brought pigs from all parts of Italy for consumption by the poor of Rome. Pork, it seems, was the dole money of the Imperial City. Yet, as at S. Giovanni, the pottery assemblage at the *Schola* Praeconum indicates the existence of a vibrant market system. Large numbers of east Mediterranean amphorae and North African tablewares from the middens demonstrate far-flung mercantile connections of growing importance. So how does this evidence square up with Whittaker's thesis?

Two points emerge from the recent archaeological reports. First, short-term fast-food production and a trend towards more regionally devolved ceramic industries seem to have accompanied the drop in density of rural sites. Second, there were changes in distribution. Tax in kind, to judge from the pattern of pork consumption, was as significant as Whittaker anticipated. However, in contrast to the regionally discrete patterns of ceramic distribution evident in southern Italy, a marked increase in the volume of imported pots is evident in cities such as Rome[9]. The major cities, in other words, were booming and attracting the rural poor, the recipients of the pork dole, leaving *agri deserti* in the provinces, as Whittaker notes. Rome's Indian Summer, like that of the wealthier villas such as S. Giovanni, was notable for its emphasis on short-term consumption.

Whether the volume of production in this reorganized community remained static, as Whittaker contends, or declined, as seems more probable, will only be clear when the many regional archaeological surveys of the moment in Italy are completed. But all the current work demonstrates that these fifth-century developments reflect that time was running out for the Roman Empire. The state system began to gasp and collapse in the early sixth century before the Byzantine and then the Lombard invasions of the peninsula. The system of ports and villas fell apart soon after AD 500, leaving ruins which fascinated the early medieval elite as they do tourists today. Whittaker's thesis and his fascinating reworking of Gibbon's drama is to some extent confirmed by the archaeology of the period. The scale of change and the eventual collapse must have seemed every bit as awful to those who experienced it as Gibbon's gothic description contends. □

Oceanology

Storms in the abyss

from P.F. Friend

ANY lingering notion that the dark waters of the deep ocean floors are uniformly calm should finally be dispelled by the vivid account of this remarkable environment provided by Hollister and McCave starting on pages 220 of this issue of *Nature*.

Their study concentrates on a 2 x 4 km area of the Atlantic Ocean, where it reaches a depth of almost 5 km, some 500 km south of Halifax, Nova Scotia. Although the surface waters there move generally eastwards, as part of the Gulf Stream, the deepest waters tend to move westwards as part of a distinctive deeper western boundary current that is cold (less than 1.9°C) and perhaps has its origins in the bottom water of the Antarctic. This cold bottom current has a remarkably high velocity of up to 0.73 m s^{-1}, similar to those measured in strongly moving surface tidal flows or in flooding rivers.

Another striking feature of the area is that it is subject to 'storm' periods of several days to a few weeks in which bottom currents intermittently reach speeds of over 0.3 m s^{-1} and are often reversed. Calculations of the variance of current speed provide a measure of the so-called eddy kinetic energy of the system. It seems that high values of the eddy kinetic energy in deep waters are usually found in areas where the eddy kinetic energy at the surface is also high, as in the Gulf Stream. The kinetic behaviour of the deep currents in storms is perhaps best visualized as an intermittent and reversing surge; there is no sign of the oscillatory periods of several seconds that are typical of surface-storm kinetics.

Because the muddy ocean floor in the area studied is rich in organic nutrients, it supports many actively burrowing organisms that soon disrupt any sedimentary features. The fact that the top layer of the floor retains sedimentary features therefore indicates that it was recently and rapidly deposited. The concentration of sediment can be as high as 12 g m^{-3} in these deep-bottom waters, similar to that in some muddy estuaries. These concentrations, coupled with the major variations in the small structures of the ocean bottom recorded in time-series of photographs, show that the vigorous movements of the bottom currents erode and transport large amounts of the fine-grained sediment. Indeed, careful examination of sediment cores from the ocean bed reveals the rapid rates of deposition of sediment and the occurrence of frequent episodes of erosion: several centimetres of mud may be deposited in the course of a few days and then removed equally rapidly. By such a process more than 3,000 times more material may have been deposited in the 10,000 years of the Holocene than is apparent from the deposition rate of 5 cm kyr^{-1} recorded in the sediments, according to the estimates of Hollister and McCave. It is common to find that the rates of short-term sedimentation (and erosion) are several orders of magnitude higher than those of long-term accumulation for the shallow-sea deposits in many old sedimentary basins but it has not hitherto been known that the same is true on the floors of deep oceans.

Considering all the deep oceans of the Earth, Hollister and McCave point to seven discrete areas, most of them tens to hundreds of kilometres across, where the suspended load of the deep-ocean water is particularly high. All the areas occur below zones of high surface-eddy kinetic energy, and probably contain deep currents which move strongly and reverse intermittently. These few, rather small areas may be the prime sources of much of the suspended muddy material of the world's oceans just as a few land areas, which have erodible soils and intermittently strong winds, seem to contribute a large part of the very fine-grained suspended terrigenous materials in the Earth's atmosphere. □

Colour vision

Direct recordings from the cone cells of a primate

from J. D. Mollon

FACED with the infinite varieties of hues and tints in a sunlit wood in spring, it can be difficult to believe that all our sensations of colour arise from just three unidimensional retinal signals. Nevertheless, our ability to see in colour depends on no more than a comparison of the relative rates of absorption of photons in the three types of cone cell within each local region of the retina and on the distribution of these ratios across the retina. The three types of cone cell contain photopigments with peak sensitivity in different parts of the visible spectrum; although direct measurements of their absorbance spectra have been possible for many years, Nunn, Schnapf and Baylor have achieved a great technical feat in obtaining the first direct electrophysiological recordings from a primate cone cell, reported on page 264 of this issue[1].

The existence of three types of retinal receptor was first suggested 200 years ago[2,3] and by 1886 the brilliant Arthur König had accurately deduced the spectral sensitivities of the cones from psychophysical studies of normal and colour-blind observers[4]. But the three types of cone remained, in effect, hypothetical constructs until the first direct measurements of the absorbance spectra of the different cone types were obtained by microspectrophotometry, in which a narrow monochromatic measuring beam is passed through the outer segment of an individual receptor cell. Nowadays relatively precise estimates of the three absorbance spectra are available for monkey and human retinas[5,6].

An absorbance spectrum — a plot of the optical density of the cell at different wavelengths — is not, however, necessarily the same as an electrophysiological action spectrum, which shows the number of photons required at different wavelengths to produce a given electrical signal. For example, it might have been the case that the electrical signal produced by an absorbed photon was dependent on wavelength. Moreover, the steep long-wavelength limbs of the absorbance spectra can be followed only down to values around one-tenth of the maximum absorbance, whereas action spectra are not so limited and it is easy to measure the intense lights needed to produce a criterion electrical signal at long wavelengths.

It is physiological action spectra that Nunn, Schnapf and Baylor have now provided us with. To measure them in the tiny (perhaps 2μm by 10μm) pigment-containing outer segments of primate cones, they adapted a clever trick that Yau, Lamb and Baylor[7] introduced in 1977 originally to make recordings from the much larger photoreceptors of the toad. Instead of trying to put a microelectrode inside the outer segment, Yau *et al.* put the outer segment inside a micropipette, sucking it gently in and allowing the mouth of the pipette to form an electrical seal round the base of the outer segment. The signal thereafter measured is a graded reduction in the current that flows continuously into the outer segment in the dark.

In their samples of tissue from macaque monkeys, Nunn *et al.* have been able to record only middle- and long-wavelength cones; the peak sensitivities of the two types of record lie quite close together in the green (540 nm) and yellow-green (570 nm) regions of the spectrum, in good correspondence with both psychophysical

and microspectrophotometric estimates. The short-wave receptors, the so-called 'blue cones', have so far eluded measurement by the new method. But this is not surprising, for psychophysical, microspectrophotometric and histological results all converge to suggest that the blue cones are relatively sparse, perhaps accounting for less than 10 per cent of all cones in human and macaque retinas. It seems that we use the blue cones only for colour vision *per se*. For the detection and resolution of contours, for stereopsis and for discrimination of movement, we rely on visual subsystems that draw their inputs only from the long and middle-wave cones[8].

Of particular interest to many psychophysicists will be Nunn *et al.*'s observation that the electrical responses of primate cones have a shorter time course than do those of rods from the same species. Such a difference has long been postulated in order to explain why our ability to resolve rapid flicker is poorer, and why the subjective duration of our sensations is greater, when our vision depends on responses of the rods rather than of the cones[9].

Building on this pioneering work of Nunn, Schnapf and Baylor, it will be possible to answer some interesting questions. First, there is the question of adaptation. Nunn and Baylor have already reported that primate rods exhibit little intrinsic gain control as the illumination level is increased[10]. Will this also be the case for primate cones? Second, will there prove to be a residual discrepancy between absorbance and action spectra for primate cones and, in particular, is the quantum efficiency the same for the short-wave 'β band' as for the primary mode of the spectral sensitivity curve? These questions will be securely answered only when microspectrophotometric and electrophysiological measurements are made concurrently on the same primate cones. Third, will there prove to be individual differences in the exact spectral positions of cone sensitivities as has been suggested by microspectrophotometric data from human eyes[6]? □

Molecular biology

Anatomy of hypersensitive sites

from Sarah C. R. Elgin

In the analysis of the structure of chromatin in animal cells, sites hypersensitive to digestion by the enzyme DNase I are generally found within the 1,000 base pairs (bp) that flank the 5′ ends of genes that are active or can be activated (see ref. 1 for a brief review). That these discontinuities in the chromatin fibre mark sites relevant to the control of gene expression has been shown in several instances, most directly in an analysis of deletion mutations at the *Drosophila Sgs4* glue protein locus[2], and they can be considered as sites of potential interaction between specific effector proteins and DNA. A critical question is that of how the DNase I hypersensitive sites are generated and maintained; answers should not be long delayed to judge by the progress that has already been reported this year or is soon to be published.

The appearance of DNase I hypersensitive sites precedes the initiation of transcription and is tissue-specific for genes so regulated. Studies of the minichromosome of simian virus 40 (SV40) and of the chick β-globin gene indicate that DNase I hypersensitive sites correspond to regions of DNA that are nucleosome free[3-5]. Since it is known that DNA in certain conformations is unlikely to form stable nucleosomes, a formal possibility is that the DNase I hypersensitive sites consist solely of a short stretch of DNA in one such conformation. In that respect there has been considerable recent interest in sites that are sensitive to S_1 and other 'single-strand-specific' endonucleases in regions 5′ to genes in supercoiled DNA and in chromatin[6,7]. Some are sensitive to S_1 nuclease but not *Bal*31 nuclease, while others show the opposite pattern[11]. The sites frequently correspond to short stretches of double-stranded DNA where one strand is all purines and the other all pyrimidines[8-10]. The exact form of the altered structure at these sites in the supercoiled DNA is unknown but it appears unlikely that truly single-stranded regions are formed[10,11].

While the available data are sketchy, it is common to observe, 5′ to genes, one of several classes of sequence capable of adopting some sort of altered conformation. Comparisons of DNA mapping data with chromatin mapping data indicate that in at least some cases, such sequences flank DNase I hypersensitive sites of chromatin instead of being an integral part of them (for example, refs 11,12). This is not to suggest that they are necessarily without influence; data both from artificial rearrangements of the SV40 genome and from *Drosophila* variants at the *Sgs4* locus indicate that sequences adjacent, or within a few hundred base pairs, can be critical for the formation of DNase I hypersensitive sites[2,13]. A model in which alternative DNA structures play a part in generating DNase I hypersensitive sites is attractive[6,7]. One's enthusiasm must, however, be tempered by the fact that there is relatively little evidence of whether alternative forms of DNA actually occur *in vivo*.

It seems likely that DNase I hypersensitive sites are generated by the interaction of nonhistone proteins with the DNA, perhaps following cues from the surrounding sequence, perhaps binding to the region itself. The challenge to isolate such proteins has recently been taken up by Emerson and Felsenfeld[14]. Using as an assay the correct assembly of the DNase I site 5′ to the chick $^{A}\beta$-globin gene, they have separated from the nuclei of chick erythrocytes, in which the gene is expressed, a protein that not only produces the requisite nuclease sensitivity but also retains a DNA fragment containing the 5′-flanking region in a filter-binding assay. Binding experiments with different DNA fragments set one boundary of the recognition site between 268 and 303 bp, and the other between 40 and 164 bp, 5′ of the transcription start site. For comparison, the DNase I hypersensitive site maps between 65 and 163 bp, micrococcal nuclease sensitivity extends to 260 bp (ref. 5) and a tract of 16 consecutive deoxyguanosine residues, sensitive to S_1 nuclease in the supercoiled form, occupies bp 178–197 (refs 9 and 10). The region of interest therefore covers both the DNase I hypersensitive site in chromatin and the most prominent S_1 nuclease sensitive site in the DNA, but not the 'TATA box' or the transcription start site. Obviously more than one critical protein–DNA interaction may be occurring.

Fortunately, several new techniques have recently been developed which improve our ability to map or 'footprint' both alterations in DNA structure and protein–DNA interactions. In a forthcoming issue of *Nature*, M.M. Becker and J.C. Wang will describe a 'photofootprinting' technique, which uses ultraviolet light to detect protein–DNA contacts as well as changes in the structure of DNA at the sequence level. The technique is based on the observation that the photochemical reactivities of DNA bases are dependent on both protein-binding and DNA structure. Breakage of the DNA backbone only at the sites of photodamage and end-labelling by any of several techniques allows a map of relative photoreactivity to be developed. The question of which conformations of DNA at 5′ sites with potential alternative structures are present *in vivo* might profitably be addressed by this method in

the immediate future.

And on page 229 of this issue, Wu introduces a new approach to analysing the position of DNA-binding proteins within or around hypersensitive regions[15]. He uses exonuclease III of *Escherichia coli* to digest chromatin within the hypersensitive site after its cleavage by a suitable endonuclease (DNase I or a restriction enzyme). The exonuclease is thought to stop when it encounters a protein, thus defining one boundary of the binding site. In an analysis of a heat-shock protein gene (*hsp70*) of *Drosophila*, a resistant (protein-bound) site is found 12–40 bp 5′ of the transcription start site in normal cells; in heat-shocked cells, however, an additional resistant site is observed in the region between 40 and 108 bp.

Techniques recently devised to cross-link protein with DNA should provide a second method for mapping these interactions, and the potential to identify the proteins involved, although at present this is frequently limited to cases where antibodies against the protein are available (for example, refs 16,17). Concerted application of these techniques could lead to a full definition of the DNase I hypersensitive site in molecular terms within the next few years. □

Archaeological dating

New method for bricks?

from E.T. Hall

AN unexpected byproduct of investigations of the chemical stability of clays employed in the storage of nuclear waste is the suggestion of a new method of dating bricks, ceramics and other materials fired in antiquity. The technique, suggested by Waddell and Fountain[1], depends on the diffusion of Ca^{2+} ions from mortar or cement layers into the clay brick. The authors report a relationship between time and calcium content at the interface of the clay brick with the mortar but base their report on only seven samples. These show that there is an increase of calcium with time, although the experimental nature of the curve relating the distance migrated by calcium to time is far from clear. The migration distances are small (< 20 μm in 200 years), whereas the matrix of bricks is comparatively coarse. An electron microprobe was used for the analyses, providing a resolution of 2.5 μm; there can be little doubt that the analytical results from the traverses across the cement–brick interface must be very 'noisy' and accurate measurement difficult to achieve, even though multiple passes were made to obtain an average result.

The new technique is interesting but still at a preliminary stage of development and its application to real archaeological dating may well be problematical. Clearly it has a long way to go before it can rival the most successful of the methods for dating fired materials — thermoluminescence. The work of Aitken[2,3] and others[4] has made thermoluminescence the standard procedure[5] for testing the authenticity of doubtful ceramics, particularly when public or private purchasers are contemplating their purchase in the saleroom. For bricks whose environment is known, so that the thermoluminescent component arising from their surroundings or from cosmic rays can be estimated, thermoluminescence can be expected to provide dating that is accurate to within ~7 per cent.

Another technique for dating bricks and other fired clays is archaeomagnetic dating[6], where the past history of the Earth's magnetic field, both in direction and intensity, is used. In the case of bricks, which will have the direction of the Earth's field induced in them at the time of firing, we do not normally know the orientation of the brick when fired and so measurement of direction of the brick's magnetic moment will not help us. However, recent measurements[7] of intensities of magnetization, which can be related to the ancient field strength, have provided some evidence that this might become a useful method of dating, albeit at a lower accuracy than is provided by thermoluminescence. □

Fractals

Aggregationism

THE problem of aggregation is both ancient, as in the manufacture of carbon black, and modern, with the recognition in the past few years that microscopic structures as different as snowflakes and colloidal precipitates may be examples of physical structures with fractional dimensions — fractals in the sense intended by Hausdorff in 1919 and more recently given wide currency by the proselytizing of B.B. Mandelbrot. One page 225 of this issue R.M. Brady and R.C. Ball report one of the most direct demonstrations so far that aggregation does yield fractal structures.

Brady and Ball are concerned only with aggregation whose rate is limited by that at which extra particles can reach the surface of a growing cluster. The circumstances therefore do not necessarily correspond to those which determine the growth of, say, a snowflake from water vapour, where the shape of the crystal may be governed by the rate at which latent heat can escape. Either way, the application of macroscopic arguments to the growth of these structures is hampered by the non-linear character of the instabilities that form on growing surfaces (departures from regular shape grow more quickly) whence the interest in the microscopic simulation introduced by T.A. Witten and L.M. Sander three years ago (*Phys. Rev. Lett.* **47**, 1400; 1981).

That model is simple enough. Put a seed particle at the centre of a finite patch of, say, a square lattice and allow fresh particles to enter the system at random places on the periphery and to make their way through the lattice by random walking, following the rule that they stick to the growing aggregate whenever they reach a neighbouring position on the lattice. Brady and Ball confirm the computer prediction for the three-dimensional lattice (that the density should be a decreasing function of the radius of an aggregate) by their neat set-up in which the electrolysis current at constant voltage is simultaneously both a measure of distance and, when integrated over time, a measure of the total mass.

As it happens, an experimental investigation of the other obvious case of aggregation — that typified by the aggregation of colloidal particles in homogeneous suspension — has also just been published (Weitz, D.A. and Oliveria, M. *Phys. Rev. Lett.* **52**, 1433; 1984). The model, in this case, is one in which the particles initially occupy many sites of a lattice, then diffuse randomly through it and stick together whenever they encounter another particle or growing aggregate. The unpublished result of the simulation (due to P. Meakin) is said to be a fractal dimension of about 1.75, which Weitz and Oliveria say they have confirmed by the measurement of individual particles of colloidal gold in aggregates formed by controlled flocculation. □

Role of RecA protein spiral filaments in genetic recombination

Paul Howard-Flanders*, Stephen C. West* & Andrzej Stasiak†

Physical and enzymatic studies on RecA protein from Escherichia coli *provide the basis for a molecular model of general genetic recombination, a novel feature of which is the role attributed to spiral filaments of RecA protein.*

IN general genetic recombination, homologous chromosomes are paired, cut and joined to form chromosomes with new linkages. To examine the underlying mechanisms, data from genetic crosses in fungi, bacteria and viruses have been used to develop models that account for the genetic data. More recent biochemical and physical studies on RecA protein, the recombination enzyme of *Escherichia coli*, allow the development of more complete molecular models for the pairing and exchange reactions involved. In this article we describe such a molecular model, introducing it with a brief review of published models and the studies on which it is based.

Models of genetic recombination

Several alternatives have been suggested to explain how homologous pairing between chromosomes is initiated: (1) when both duplexes are nicked by an enzyme at identical positions in each chromosome[1]; (2) when one duplex carries a single strand gap and the other is nicked[2,3] (Fig. 1*a*); (3) when one duplex is nicked and a strand is displaced by local DNA synthesis[4] (Fig. 1*b*); (4) when both duplexes are replicated locally[5]; (5) when particular sites in DNA are recognized by initiation enzymes[6]; (6) when a two-strand break is made (Fig. 1*c*)[7]; or (7) when one duplex carries a single-strand gap and the other is intact[8–11] (Fig. 1*d*). The more recent models were designed to form unequal lengths of heteroduplex DNA, as required by the data on meiotic recombination in fungi[7,12,13]. However, it has proved difficult to determine from genetic data how recombination is initiated, and the choice between models remains open.

Homologous recombination also serves a function in the repair of certain types of DNA damage. In yeast, for example, the repair of double-strand breaks depends on recombination with a homologue[14]. Similarly, the switch between mating types is attributed to gene conversion at the mating type locus, initiated by a double-strand break[15]. In bacteria, recombination is initiated by DNA containing incised cross-links[16] or by post-replication gaps which induce sister exchanges with an efficiency close to unity[8].

In *E. coli*, both general genetic recombination and post-replication repair require *recA*$^+$, a pleiotropic gene that is activated by DNA damage[17,18]. The *recA*$^+$ gene product[19–23] is a protein of 38,000 molecular weight (M_r) and known sequence[24,25] that polymerizes into spiral filaments. It has a single-strand DNA-dependent protease activity for SOS induction in response to DNA damage[23], and it mediates enzymatic reactions with DNA of relevance to recombination[3].

DNA binding sites

In the presence of the non-hydrolysable ATP analogue, ATP(γ-S), RecA protein tends to aggregate at low *p*H into long filaments[26], and at neutral *p*H it condenses on duplex DNA in rod-like filaments[27]. On careful examination of shadowed specimens in an electron microscope, the filaments formed on DNA are seen to be striated and to consist of right-handed spirals of pitch 100 Å and diameter roughly 100 Å (Fig. 2*a*, *b*). When negatively stained, the spiral filaments appear to be deeply grooved with space between adjacent turns. They occur singly or in bundles in quasicrystalline alignment and appear hexagonal in cross-section[28].

The number of turns of spiral filament needed to cover a circular plasmid of defined length is very reproducible, indicating that RecA binds stoichiometrically to duplex DNA. There is one turn per 18.6 base pairs (bp) and there are 6.2 RecA monomers per turn, as determined by counting RecA striations on plasmid DNA and by measurements of the linear density of the filaments[29,30]. Evidently the spiral protein filament is wound along the phosphodiester backbone of the duplex with each monomer binding to exactly the same number of base pairs[28,29,31]. This number may be 3 bp, as assumed in Fig. 4, but not all methods give the same value[32]. Measurements of overall length of these filaments show the DNA to be stretched by 50% beyond the normal B-DNA length. At 18.6, instead of the usual 10 bp per turn, the duplex is underwound by nearly 50%, the angular twist between adjacent base pairs being reduced from the normal value of 36° to about 20° (refs 28, 29).

RecA protein filaments also form on circular single-strand DNA in the presence of ATP, but are neither stretched nor striated. Some complexes are seen by electron microscopy to be of similar length to B-DNA, but others are collapsed on themselves. They are unstable and few are seen unless single-strand binding protein is present, or they are fixed with glutaraldehyde[33].

Certain features of RecA spiral filaments have been revealed by X-ray crystallographic methods. RecA protein crystallizes in hexagonal and in tetragonal crystals, which have been examined by X-ray diffraction[34]. The hexagonal crystals which form at low *p*H appear to contain spiral chains with 6 RecA protein monomers per turn of length 84 Å and symmetry P6.1 (Fig. 2*c*). Since the spiral filaments seen by microscopy are right handed, we think the monomers may also be arranged in right-handed spirals within the crystals. The X-ray diffraction studies on hexagonal crystals prove that the spiral filaments consist of RecA monomers arranged head to tail in equivalent positions (Fig. 2*c*), and not in a sequence of dimers or tetramers[34]. The head-to-tail orientation of monomers provides a physical basis for the functional directionality of the enzyme in strand exchange reactions[35–37]. This directionality can be understood if each monomer has two DNA binding sites, one for each DNA molecule to be paired. In contrast there would be no basis for directionality if each monomer had only one DNA binding site and the functional unit was a symmetrical dimer.

In summary, these physical methods show that RecA protein binds to DNA stoichiometrically and forms right-handed spiral

The gap is repaired and the two cross-overs are resolved to form recombinants. The intact homologue is cut only at the resolution of the cross-overs[11].

filaments of regular structure with all the monomers orientated in the same direction.

Initiation, pairing and strand exchange

RecA protein binds cooperatively to single-strand DNA and has a single-strand DNA-dependent ATPase activity[38,39]. Homologous pairing by RecA protein was first detected *in vitro* when single-strand fragments were paired with circular duplex DNA to form stable complexes[40–43] referred to as displacement loops or D-loops. However, the pairing and strand exchange reactions of this protein have been more fully characterized in reactions with circular single-strand and full length linear duplex DNA[44,45]. RecA protein binds to single-strand DNA to form an initiation complex that is capable of immediate pairing with duplex DNA[46,47]. One strand of the linear duplex is transferred to the single-strand circle, to form a nicked circular heteroduplex and a linear single strand[44]. The strand exchange requires ATP and advances in the 5′ to 3′ direction along the original single strand at a rate of only a few bases per second[35,36]. It works best if single-strand binding protein (SSB) is added to stabilize the initiation complex, and has the advantage that the substrates, intermediates and products of the reaction can all be assayed.

Homologous pairing and strand exchange reactions also occur between two duplex molecules if one of them contains a small single-stranded gap (gapped DNA)[9,10]. When gapped circular DNA is incubated with RecA protein and linear duplex DNA containing a 3′ end complementary to the gap, RecA pairs the molecules starting in the gap[48,49]. Strand exchange then proceeds in the 5′ to 3′ direction in the gap and continues along the adjoining duplex to form two heteroduplexes[11,37]. When the gapped DNA is incubated with nicked circular DNA, pairing at the gap leads to the 3′ ends being exchanged and to the formation of figure-8 DNA structures containing Holliday cross-overs[50].

The reaction between gapped and intact circular duplex DNA is similar. Again, homologous pairing initiated at the single-strand gap, leads to strand exchange and the formation of heteroduplex DNA, but in this situation the length of heterodu-

RecA monomers are shown as spheres, but their exact shape is unknown. *c*, Diagram of RecA spiral filament in crystals of RecA protein free of DNA, based on X-ray crystallographic data. Arrows indicate alignment of monomers[34].

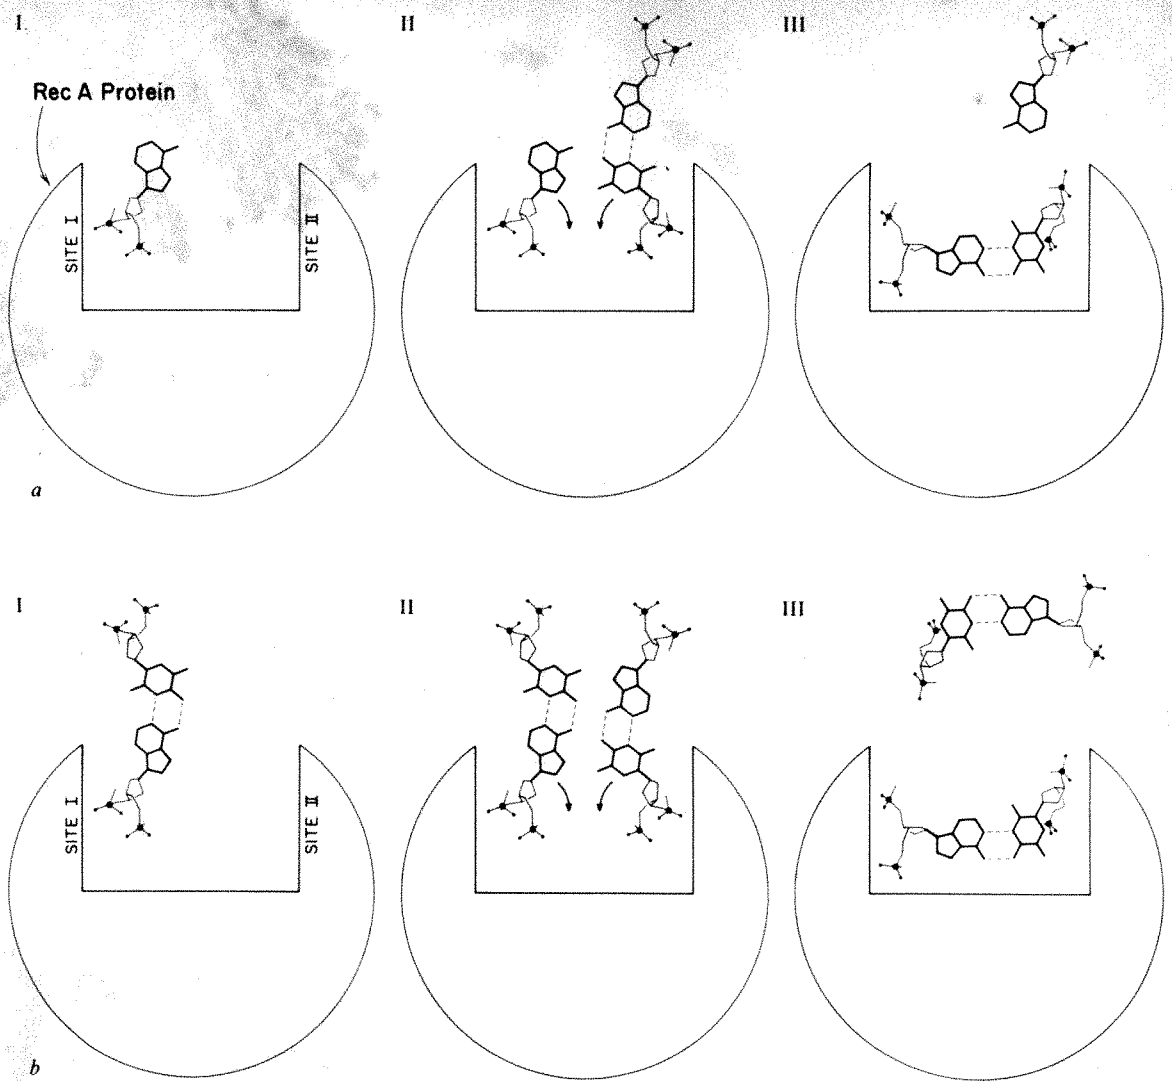

Fig. 3 A two DNA binding site model for RecA protein and a proposed mechanism for homologous pairing and strand exchange. Each base is shown in axial view with two phosphates. The sugar phosphates are unwound to about 20° between adjacent base pairs. RecA protein is about 50 Å in diameter, 60% larger than shown in this diagram. *a*, Pairing and strand exchange between single strand and duplex. (I) A single-strand binds at site I of RecA protein to form an initiation complex. (II) Initiation complex binds to one strand of a duplex at site II with homologous pairing by hydrogen bonding (bonds not shown) in the wide groove. (III) RecA protein rotates the bases into the heteroduplex position. *b*, Pairing and strand exchange between two duplexes. (I) One strand of the duplex binds at site I to form a duplex initiation complex. (II) The duplex initiation complex binds to the second duplex with homologous pairing by hydrogen bonding (bonds not shown) in the wide groove. (III) RecA protein rotates the bases into the heteroduplex configuration.

plex is limited by topological constraints and an interwound figure-8 carrying two Holliday cross-overs is formed[10,11].

Search for homologous contacts

Several mechanisms for homologous pairing can be visualized: (1) RecA protein may move two DNA molecules relative to each other until homologous sequences come into alignment, or (2) pairing may result from random contacts between DNA molecules. In support of the latter mechanism, RecA pairs single-stranded and duplex molecules if they share a common base sequence of 100 bp or more, but fails to do so if homology is limited to 30 bp. The rate of homologous pairing is directly proportional to the length of the DNA molecule, even if partially non-homologous[51]. Moreover, RecA protein forms aggregates with DNA, that are readily seen by electron microscopy and must locally increase the concentration of both naked and complexed DNA[27,33]. These results are consistent with a pairing mechanism in which DNA, aggregated by RecA protein, makes an increased number of random contacts at multiple points along chains. Such contacts will of course be transient unless homologous sequences touch and pairing is established.

The alignment of identical base sequences at homologous pairing presumably depends upon sequence specific complementary hydrogen bonding between DNA chains. Two forms can be visualized: (1) The two strands of a duplex may be separated and able to pair as Watson–Crick heteroduplexes. This form of pairing may occur in the absence of RecA when superhelical circular phage DNA is annealed with homologous single-strand fragments to form D-loops[52]. However, it is not at all clear that this form of pairing occurs in RecA-mediated reactions, particularly since *in vitro* tests for RecA-mediated strand separation of duplex DNA in advance of pairing have given negative results[53–55]; (2) Initiation complexes may pair in the wide groove of the duplex. Complementary base pairing between a single-strand and a fully base-paired duplex could depend on hydrogen bonds between the oxygen and amino groups at positions 4 on pyrimidines and positions 5 and 7 on purines. A four-stranded structure that depends on such bonding has been proposed[56–58]. Poly(dT) · poly(dA) · poly(dT) is not of exactly the same structure, but is an example of a stable three-stranded deoxyribose polynucleotide chain[59].

Although we cannot rule out either form of pairing on the

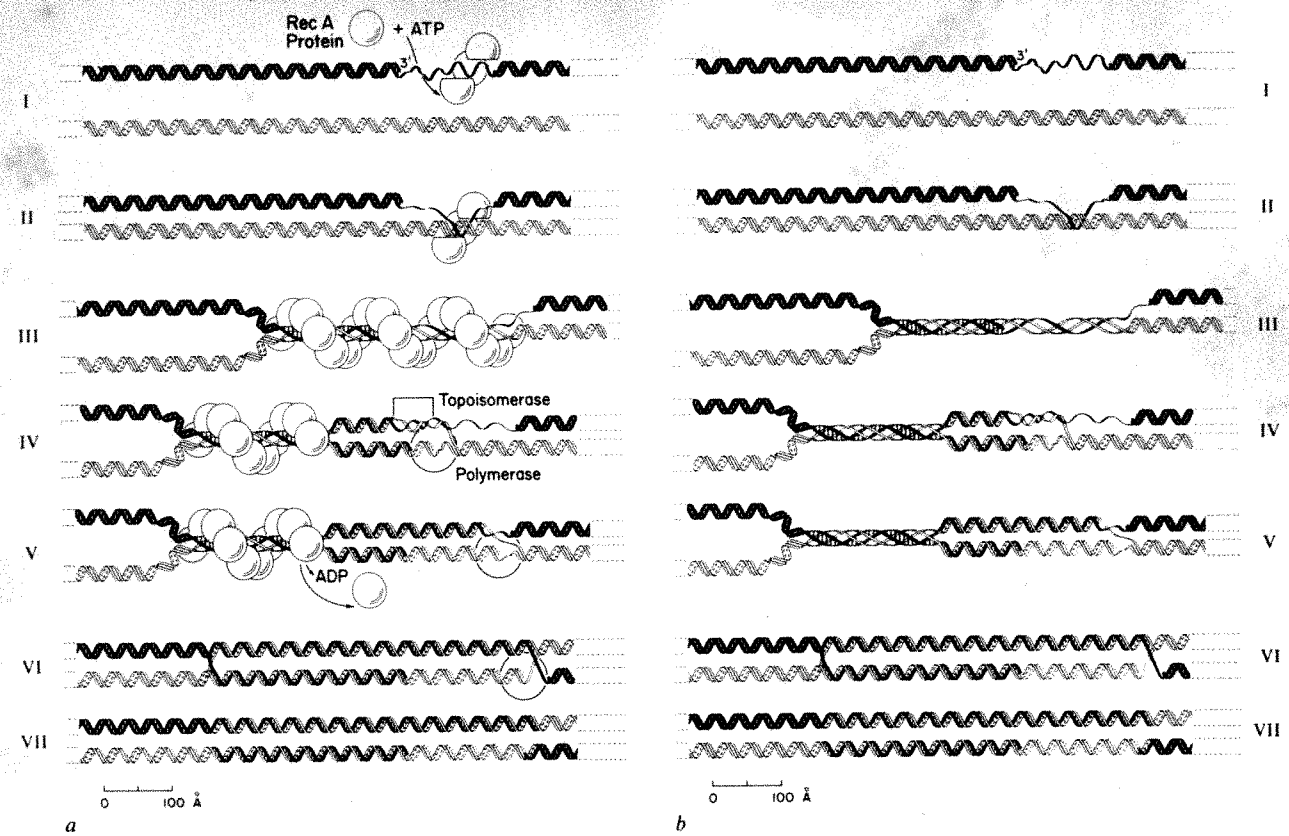

Fig. 4 An enzymatic model for genetic recombination. *a*, Complete model with enzymes; *b*, DNA only. (I) RecA protein binds cooperatively to the single strand in a gapped duplex to form an initiation complex, in preparation for pairing. Watson–Crick base pairs are shown as rods linking the DNA twin helices. (II) The initiation complex binds to the intact duplex, making transient contacts until a homologous site is reached. For clarity, the initiation complex is drawn with only a few protein monomers, but in reality is likely to extend over hundreds or thousands of nucleotides. (III) When homologous contacts are made and the strands become paired locally, the initiation complex acts as nucleus for further cooperative binding, which extends the RecA spiral filament around all three paired strands. As more RecA binds, the spiral filament extends around both duplexes drawing them together, wide groove facing wide groove. RecA binds to duplex molecules in response to pairing. (IV) The spiral filament is extended further by the addition of more monomers to the head end. RecA monomers at the tail end switch the strands to the heteroduplex configuration and may then be released from the DNA. The upper heteroduplex is relaxed by topoisomerase I. DNA polymerase starts to repair single strand gap by adding nucleotides to 3′ end (broken lines). (V) RecA driven branch migration continues with hydrolysis of ATP. (VI) Growth of the spiral filament ceases and the last RecA monomer dissociates, leaving single strand cross-overs, which are then resolved enzymatically. The crossover on right is generated by switching the base stacking (isomerization). (VII) Mismatched base pairs in the heteroduplexes are corrected enzymatically and mature recombinants are formed.

basis of experimental data, we think wide groove pairing to be more likely because of the failure to detect strand separation before pairing and because wide groove contact would hold the strands in position for the ensuing strand exchange reaction. Moreover, it is valid for pairing between single-stranded and duplex DNA as well as for the pairing between two duplexes that should occur in reactions between gapped and intact duplex DNA[9–11] (see also Fig. 3*a*(II), *b*(II)). Although stable four-stranded polydeoxyribonucleotide chains have not been found, they may be formed when two duplexes are held together within a spiral filament. However, the duplexes probably would not be in the normal B-form, nor in a fully paired four-stranded structure with 3.4 Å axial spacing as has been proposed[56,57]. Since RecA spiral filaments on duplex DNA are regular structures in which the DNA is underwound and stretched by 50% (refs 28, 29), the four-stranded structure is likely to be regular rather than a mixture of left- and right-handed turns, and to be symmetrical about the helical axis.

Surprisingly, strand exchange reactions do not require the substrate to be undamaged or even that the duplexes are fully homologous. For example, in a three-strand reaction, strand exchange is affected very little by deletions of 10 or 20 bp[60,61] or by pyrimidine dimers[62]. Similarly, deletions of a few base pairs in one duplex do not block strand exchanges between two duplexes[50]. Thus, in contrast to the initiation of homologous pairing which is sensitive to departures from homology, the strand exchange reaction advances along each duplex with little regard for small deletions or base damage.

RecA binding to duplex DNA

The binding of RecA protein to DNA molecules exhibits several unexpected features. In the presence of ATP, it normally binds only transiently to covalent circular duplexes. However, the addition of homologous single-strand DNA fragments results in a more stable form of binding of RecA to the double-stranded DNA, which then becomes temporarily immune to subsequent pairing with single-strand fragments[63–65]. This immunity may be due to the RecA protein which, starting from the paired initiation complex, binds cooperatively to the circular duplex and causes local underwinding. The remainder of the form I DNA becomes overwound and the whole molecule becomes immune to pairing. Further evidence for underwinding by RecA is obtained in similar reactions in the presence of topoisomerase I. Again the addition of homologous single strands leads to extensive RecA binding and to a marked reduction in DNA winding number[54,64].

In summary, RecA binds to ssDNA to form initiation complexes which are ready for pairing, but it binds to duplex DNA in response to homologous pairing, forming a complex which is immune. These results provide additional evidence that each RecA monomer has two DNA binding sites (Fig. 3*a*). Initiation complexes formed by interaction of the ssDNA fragment with

site I, pair with duplex DNA which binds at site II. Since the resulting ternary complex acts as a nucleus for further cooperative RecA binding beyond the terminus of the single stranded fragment, the duplex DNA becomes covered by RecA protein and is subsequently immune to further pairing.

A molecular model for recombination

Based on the information discussed above, we have constructed a molecular model for general genetic recombination in *E. coli*. It differs from previous models by proposing that RecA protein forms a spiral filament that surrounds the paired DNA molecules. The strand exchange reaction takes place within the spiral filament and switches base pairing to form two heteroduplexes. To illustrate this mechanism, we show a diagram of an exchange between two duplexes initiated at a single-strand gap, but anticipate that this mechanism may be applicable to recombination initiated in other ways.

The assumptions made in developing this model are as follows: (1) Each RecA monomer has two distinct DNA binding sites, the primary site and the secondary site (Fig. 3*a*(I) and (II)). (2) In an initiation complex, the primary binding site in each RecA monomer is filled by single-strand DNA. (3) Pairing is between an initiation complex and a naked duplex. (4) The RecA spiral filament winds round the paired DNA molecules and dissociates after strand exchange.

Figure 4a shows an outline of the proposed molecular model for recombination between two duplexes, and Fig. 4b shows the same model with enzymes removed, so the DNA strands can be seen more clearly. In this scheme, genetic recombination is initiated by the duplex containing a single-strand gap. Since RecA protein forms initiation complexes on single-strand DNA[46], we will assume it also does so on gapped DNA (Fig. 4*a*I), binding initially to the single-stranded DNA in the gap and subsequently along the adjoining duplex[27]. Once formed, initiation complexes pair with naked duplex DNA (Fig. 4*a*II). For clarity, the initiation complex is drawn in Fig. 4 with only a few protein monomers, but in reality is likely to be many times longer.

Homologous pairing between gapped and intact duplex molecules may occur when the initiation complex (Fig. 4*a*I) with single-stranded DNA at site I (Fig. 3*a*I), makes homologous contacts with a naked duplex, winding around all three strands (Fig. 4*a*II) with the duplex at site II (Fig. 3*a*II). Compensating left-hand turns which must form outside the paired regions, are not shown[58]. The paired initiation complex may serve as a nucleus for further cooperative binding, extending the spiral filament to the end of the gap and along the adjoining duplex, drawing both duplexes together (Fig. 4*a*III). In a similar way, when site I is filled by duplex DNA, it behaves as an initiation complex and is again capable of interacting with a naked duplex which binds in site II (Fig. 3*b*II). Thus, a single mechanism suffices for both three- and four-strand interactions. We will assume that the filament is orientated and grows by accretion at one end, which we will call the head end, and dissociates by loss from the tail end, the head to tail direction being set by the 3′ (head) to 5′ (tail) direction along the single strand. Once an initiation complex has established homologous contacts with a duplex, and the paired strands are surrounded by the spiral protein filament (Fig. 4*a*III), the strand exchange reaction may proceed. We suggest it may occur at the terminal monomer at the tail end and depend upon allosteric changes associated with ATP hydrolysis, in which the bases are rotated out of their original Watson–Crick pairing to form heteroduplexes as shown in Fig. 4*a*(III) and (IV) and more clearly in a plane at right angles to the helical axis in Fig. 3*a*(III) and *b*(III). In space-filling molecular models, the bases are easily rotated into the required positions by rotation mainly about phosphate-oxygen bonds.

Since each RecA protein binds to more than one nucleotide, it may switch several base pairs at a time. Figure 4*a*(IV) and (V) show the terminal monomer switching 3 bp and then dissociating, leaving the next monomer to perform the same reaction. Thus, we visualize that the spiral filament grows at the head end by monomers binding cooperatively, drawing the duplexes together, while monomers are released from the tail end as heteroduplex DNA is formed. The length of the spiral filament may therefore be variable, depending upon the balance of accretion at the head end dissociation from the tail end. The reaction will be completed when RecA protein, for whatever reason, fails to add further to the growing end, and the last monomer of the spiral filament dissociates.

Of the two heteroduplexes formed, the lower one should be free to coil into a relaxed duplex because of the single-strand gap, while the upper heteroduplex, having no gap, will be constrained but may be relaxed by topoisomerase I (Fig. 4*a*(IV)). The reaction is completed by a switch in base stacking referred to as isomerization[4] to provide the template needed for gap repair by DNA polymerase and ligase (Fig. 4*a*(V) and (VI)).

At this point, the gap has been repaired, the two duplexes are freed from the spiral filament, and they are joined by two single-strand cross-overs (Fig. 4*a*(VII)). They are converted to mature recombinants by the enzymatic resolution of cross-overs and the repair of mismatches in the heteroduplexes[50]. The endonuclease activities performing these functions are still to be purified and studied.

Future prospects

Several features of the proposed enzymatic model require further investigation. The basic structure of homologous pairing has not been established. RecA binding to DNA and the structure of the resulting complex require further examination. Conflicting results on the stoichiometry of RecA binding need to be resolved. We do not know what triggers a strand exchange or how it takes place. We do not understand RecA binding or its release from DNA following strand exchange, nor why it uses so much ATP. The structure of RecA protein is still to be determined. Other enzymes, notably those for resolving single-strand cross-overs and for mismatch repair in heteroduplex DNA, are needed to fill important gaps in the enzymology of genetic recombination.

Sedimentation under deep-sea storms

C. D. Hollister* & I. N. McCave*†

* Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA
† School of Environmental Sciences, University of East Anglia, Norwich NR47TJ, UK

Fast currents, high concentrations of suspended sediment and grooved mud beds are associated with erosion in frequent abyssal storms where a fast deep mean flow is augmented (or reversed) by intense intermittent currents. This occurs about 5 km below the Gulf Stream or its rings. The waning phase of a storm results in development of bedforms and rapid deposition of a mud blanket. Several other regions of the world ocean display evidence of abyssal storm activity.

REPEATED sampling of an area at 4.8–4.9 km depth lying under the path of the Gulf Stream or its warm-core rings revealed extremely high current velocities (up to 0.73 m s^{-1} (ref. 1)), suspended sediment concentrations up to 12 g m^{-3} (ref. 2) and bedform development. All these varied in time. The area is the lower continental rise south of Halifax, Nova Scotia (Fig. 1), and the measurements were taken as part of the High Energy Benthic Boundary Layer Experiment (HEBBLE)[3–5]. The experiment aimed to develop and test a coupled bottom Ekman layer and sediment transport model for cohesive sediment over uniformly distributed bed roughness[5]. Regional investigations in HEBBLE have provided numerous hydrographic[6,7], photographic[8], sedimentological[9], current velocity[1,10–12], light transmission[13–15], and suspended sediment[2,16,17] data. These have been used to select a 4 × 2 km box on the lower continental rise at 40°27′ N 62°20′ W where bed roughness is uniform, bed slopes are low (<1:100) and currents are intermittently fast (Fig. 1). The Nova Scotian Rise was first investigated because earlier data on sediments, photographs and currents suggested active sediment transport in the area[18–20].

Most sediment is carried to the depth of the continental rise by debris flow and turbidity currents. Subsequently, bottom currents produce two well-defined deposit types: those dominated by reworked current-deposited sediment, exemplified by parts of the eastern margin of the United States[21,22], and those where current reworking is slight, such as the margin off northwest Africa[23–26]. The lower Scotian Rise lies downstream of the Laurentian Fan, a major sediment accumulation produced by downslope sediment transport[27,28]. This is a probable source of fine material moving over the HEBBLE site in a deep western boundary current (which is not the 'western boundary undercurrent' comprising Norwegian Sea overflow water; this occurs above 4,000 m on the rise[10,29], Fig. 1*a*).

Here we draw together diverse data bearing on the rapid erosion, transport and deposition of sediments on the lower Nova Scotian Rise and on the driving forces, a combination of a strong mean component (DC current) with strong fluctuating components (AC current). We then examine the implications for sediment dispersal and deposition in the deep sea.

Sedimentology and stratigraphy

The 2 × 4 km HEBBLE box (Fig. 1*b*) was sampled with more than 30 box cores in July 1982. Over this area the upper unit is a ~4-cm layer of soft brown mud with a silt/clay ratio of 1.70, foraminiferal sand content of 6% and water content (% wet weight) of ~50.0%. The thickness of this layer measured in cores and on X-radiographs varies between ~0.5 cm and 12.5 cm. Its vane shear strength is uniformly low at ~0.4 kPa, rising rapidly to ~4 kPa in the underlying layer of foram clayey silt[30], whose water content decreases from 45.8% at the top of the layer to 36.9% at a depth of 14 cm. This underlying unit is about 30 cm thick, is extensively burrowed (live worms have been found down to the base of the unit) and is probably all Holocene in age as it contains *Globorotalia menardii*. The foram mud contains 1–30% sand, chiefly of planktonic foraminifera. Two longer cores have a gravelly mud of presumed late Pleistocene age beneath the Holocene.

Internally, the surface mud unit shown in Fig. 2 is variably burrowed and laminated. Some burrows are large and terminate in mounds, others are a filamentous network. The uniform physical properties of this surface layer suggest rapid deposition. This is corroborated by ^{234}Th ($t_{1/2}$ = 24 days) distributions showing penetration of the radionuclide to depths as great as 6 cm (ref. 31). A balance must be struck between introduction of this material by advection (sediment deposition) and (biological) mixing, parameterized as a diffusivity[32,33]. The best estimate

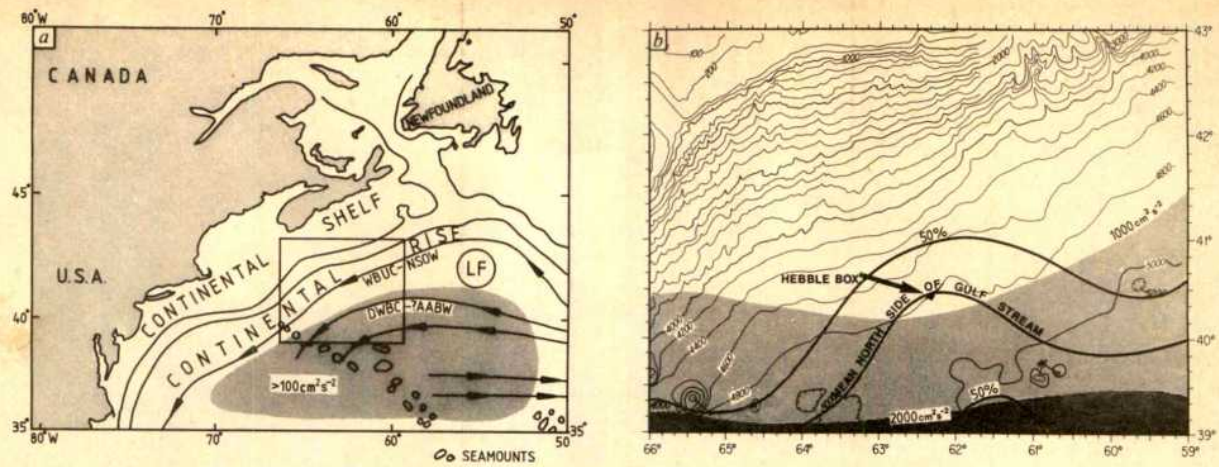

Fig. 1 Location of the HEBBLE box on the Nova Scotian continental rise. *a*, Physiography of the region with the paths of the Western Boundary Undercurrent (WBUC) transporting Norwegian Sea Overflow Water (NSOW) and a Deeper Western Boundary Current (DWBC) with cold ($\theta < 1.82$ °C) water of possible Antarctic Bottom Water (AABW) origin[6,29], and, stippled, the region of high abyssal kinetic energy ($>100\ cm^2\ s^{-2}$)[38,39]. *b*, Contoured enlargement of the slope–rise province with location of the HEBBLE box, the mean position of the northern side of the Gulf Stream[73] and its ±50% limits, and, shaded, the region of high surface kinetic energy ($>1{,}000\ cm^2\ s^{-2}$)[74]. Bathymetry of *b* courtesy of Dr A. N. Shor. LF, Laurentian Fan.

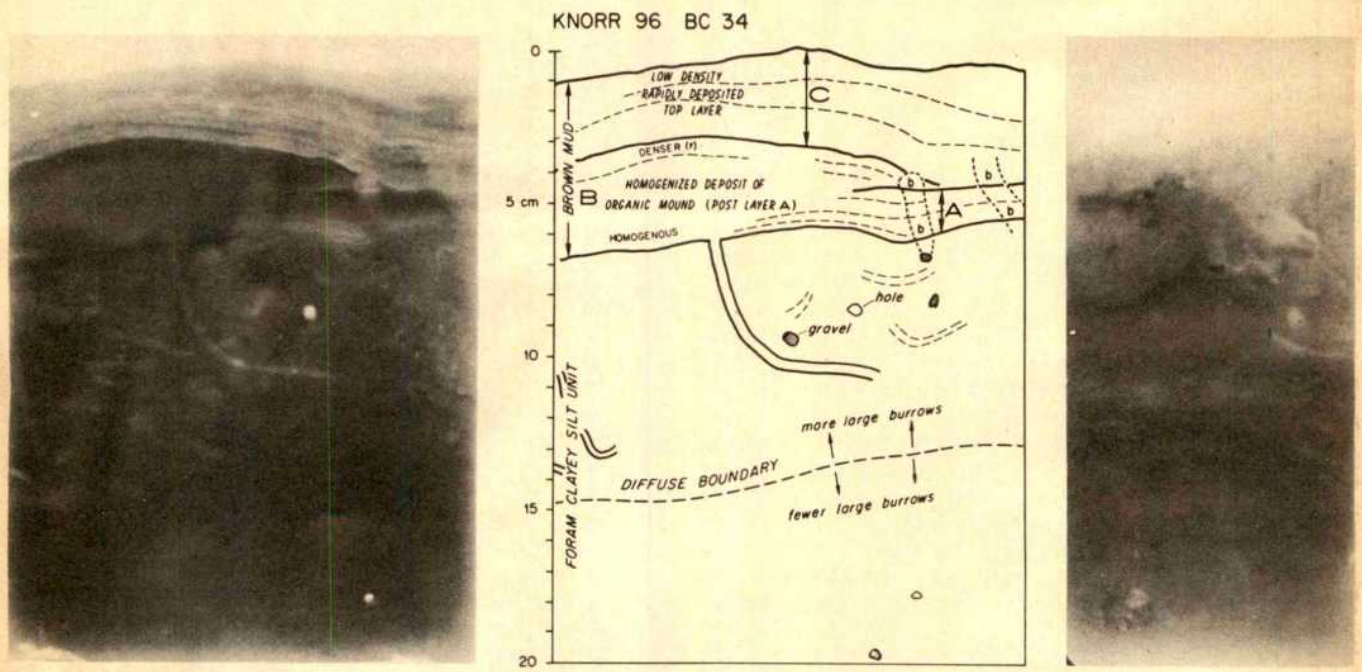

Fig. 2 Left: X-radiograph of the uppermost sediments in *Knorr* Cruise 96 (July 1982) box core 34. Centre: interpretation of the internal structure showing two depositional events (A and C) separated by an episode of mound construction (B). Right: an X-radiograph from box core 2 showing burrow-mixed upper part of the sediment column containing fine gravel (dark grains).

from one site is a deposition rate of 1.42 cm per month (17 cm yr^{-1}) and mixing parameter of 85 $cm^2\ yr^{-1}$ (ref. 30), values confirmed and extended by analysis of more samples by our colleagues D. DeMaster and C. Nittrouer[31]. These extremely high rates require very high suspended sediment concentrations (~100 g m^{-3}) occurring intermittently over a few months[30]. Deposition is often followed by rapid biological mixing of the sediment, a feature well shown by some X-radiographs (Fig. 2).

Detailed size analysis of 20 samples from 1–5 mm depths taken in July 1982 and June 1983 reveal a marked change in the material present. At depth, below the surface brown mud, on both occasions the silt fraction (2–63 μm) contained two modes at ~4 μm and ~14 μm. However, the surface 4 cm in July 1982 showed only a single peak at ~14 μm (ratio of % at 14 μm to % at 4 μm = 2.99 ± 1.38) whereas in June 1983 the bed was quite different with a clearly bimodal size distribution and a peak–height ratio of 1.42 ± 0.24 (±1 s.d.). The unimodal surface layer deposited before July 1982 must have been laid down in conditions of higher shear stress, suppressing deposition of the finer mode. Taking the preliminary *in situ* settling velocities (from trials of the optical tube of R. Zaneveld) for the fine mode to be 5.5×10^{-4} cm s^{-1}, the boundary shear stress under which the 1982 bed was deposited, preventing deposition of 4 μm silt, was >0.005 Pa (shear velocity >0.22 cm s^{-1}), while the 1983 bed was laid down under a lower stress[34]. Many X-radiographs reveal a laminated upper 5 cm of the bed, thus the bimodal deposit of 1983 could not have been formed by biological mixing-in of fine sediment deposited on top of the 1982 layer. We conclude that the bed of July 1982 had been completely eroded and that a new deposit of 'bimodal mud' up to 4 cm thick had formed since then. Again, our inference is

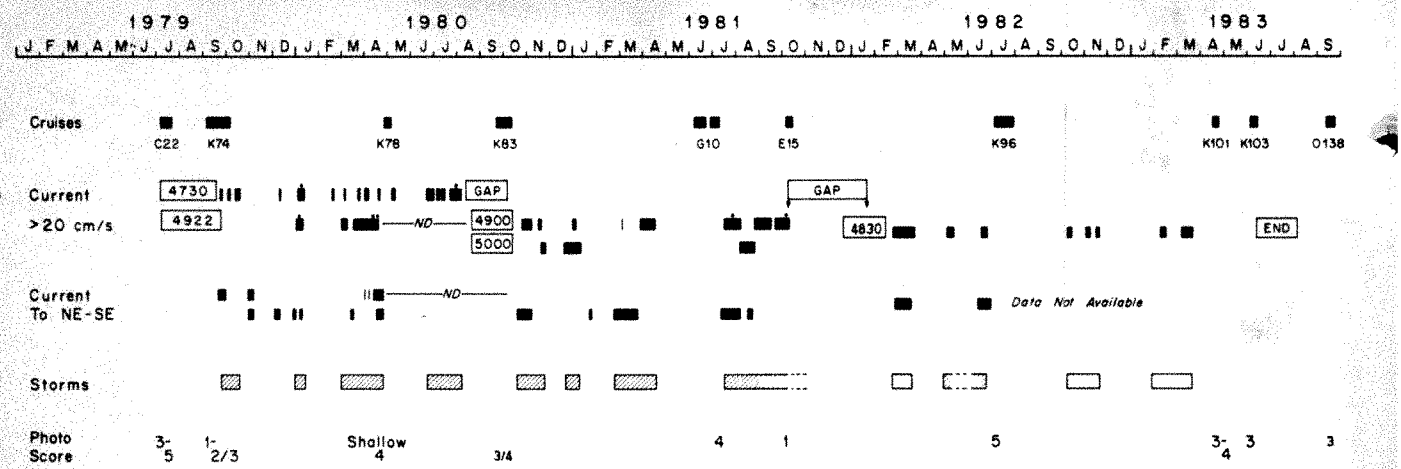

Fig. 3 A time-series of: *a*, cruises to the Nova Scotian rise in HEBBLE by Research Vessels C = *Conrad*, K = *Knorr*, G = *Gyre*, E = *Endeavor*, O = *Oceanus*; *b*, times when the currents were $>0.20\ m\ s^{-1}$ and, with a dot above the block, $>0.40\ ms^{-1}$ (courtesy of Dr M. Wimbush and Dr G. Weatherley; data for October 1980 to June 1982 in Weatherley and Kelley[6] and Koenig *et al.*[8]); *c*, times when currents flow to the east indicating eddy reversal of the mean flow, from the data sources for speed; *d*, times when the combination of speed and direction can be called a storm—this includes some lulls in the storm(s); *e*, scores (based on Table 1 criteria) of the suites of photographs from the vicinity of the HEBBLE box for cruise G10 onwards, for the deepest stations of K78, and for a 4,950 m station for K83. The range of C22 and K74 scores is discussed in the text.

one of extremely rapid erosion and deposition in this area, at rates which would not be thought low in an estuarine environment.

Photographs and currents

We have had at least one cruise per year to the Nova Scotian Rise since 1979, returning photographs from between 4,750 and 4,950 m (Fig. 3). Gross bedform zonation of the rise shows evidence of more tranquil conditions where the bed is shallower than 4,500 m and of faster currents below 4,750 m with very common longitudinal ripples below 4,850 m[8,35]. The zone between bottom depths of 4,750 and 4,950 and from 61 to 64°W was photographed in July and September 1979. These and the subsequent photographs can be assigned to a position in a rough scale of relative importance of erosion or deposition on the basis of the many features observed (Table 1) (compare with ref. 36, p. 357). It is not possible to calibrate this scale properly, though grooving (a score of 1) observed in October 1981 was associated with currents which exceeded $0.4\ m\ s^{-1}$ in the preceding 2 weeks (Fig. 3), and the tranquil end (a score of 5) has currents less than $\sim 0.05\ m\ s^{-1}$. It is unlikely that velocities for scores 2 to 4 can be obtained by linear interpolation.

The large-scale spatial variability displayed by the 1979 photographs also contains a strong temporal signal. In July the area was all at the depositional end of the scale, from 3 to 5 on the criteria of Table 1, with the scores of 4 and 5 occurring at shallower depths and 3 at depths over 4,900 m. In September the photographs were taken during a period of strong currents. Two of the stations between 61 and 61°30′ W at 4,840 and 4,920 m showed pronounced grooving, exhumed tubes and other indicators of erosion. Other stations rating scores of 1 to 2 occur along the south (deeper) side of the photographed region. The lowest scores at this time are 2 to 3 at 4,830 m depth. The most intense effects were seen in deeper water with intense scouring at two stations in the east of the region. A circular area incorporating the two scoured stations would be $\sim 10^3\ km^2$ but (the affected region might be more extensive along isobaths).

From 1981 onwards all photographs were precisely navigated by bottom transponder in the HEBBLE box. They display enormous temporal variability (Figs 3, 4), ranging from the most severe erosion to tranquil deposition with organic reworking, ratings of 1 to 5 on the criteria of Table 1. The end members are represented by the areas photographed in October 1981 on *Endeavour* 75 (score 1) and July 1982 on *Knorr* 96 (score 5) (Fig. 4*a*, *c*). Over an area the size of the HEBBLE box the photographed bed condition is spatially very uniform at a given time. During *Knorr* 96 the 16 sub-areas had over 20 photographs taken in each, and none rated a score less than 4. Current velocities measured about 35 km south of the EN 75 photographs during the previous 10 days (1–8 October) were all $>0.30\ m\ s^{-1}$ on daily average, and for 2 days they were $>0.40\ m\ s^{-1}$ (ref. 6). During *Knorr* 96 the photographs show surfaces with mounds, scattered faecal pellets, organic tracks and trails, various animal holes in the mud and occasional fine lineations. For the week before the start of the photographic survey, currents at 59 m above bottom (mab) in the HEBBLE box were $<0.10\ m\ s^{-1}$ and for half the time they were $<0.06\ m\ s^{-1}$.

At intermediate speeds, 0.05 to $0.15\ m\ s^{-1}$, deposition of silt occurred with development of barchan-like ripples in ~15 μm silt containing ~25% clay and <10% sand (Fig. 4*b*). The steeper faces on these bedforms suggest a measure of non-cohesive behaviour on the part of these clayey silts. The barchan ripples grow on the downstream side of biogenic mounds. It is not clear what dynamical condition controls the difference between formation of either single tails (mound-and-tail structure) or 'swallow-tailed' barchan ripples downstream of mounds. These

Table 1 Photographic features indicative of erosion/deposition

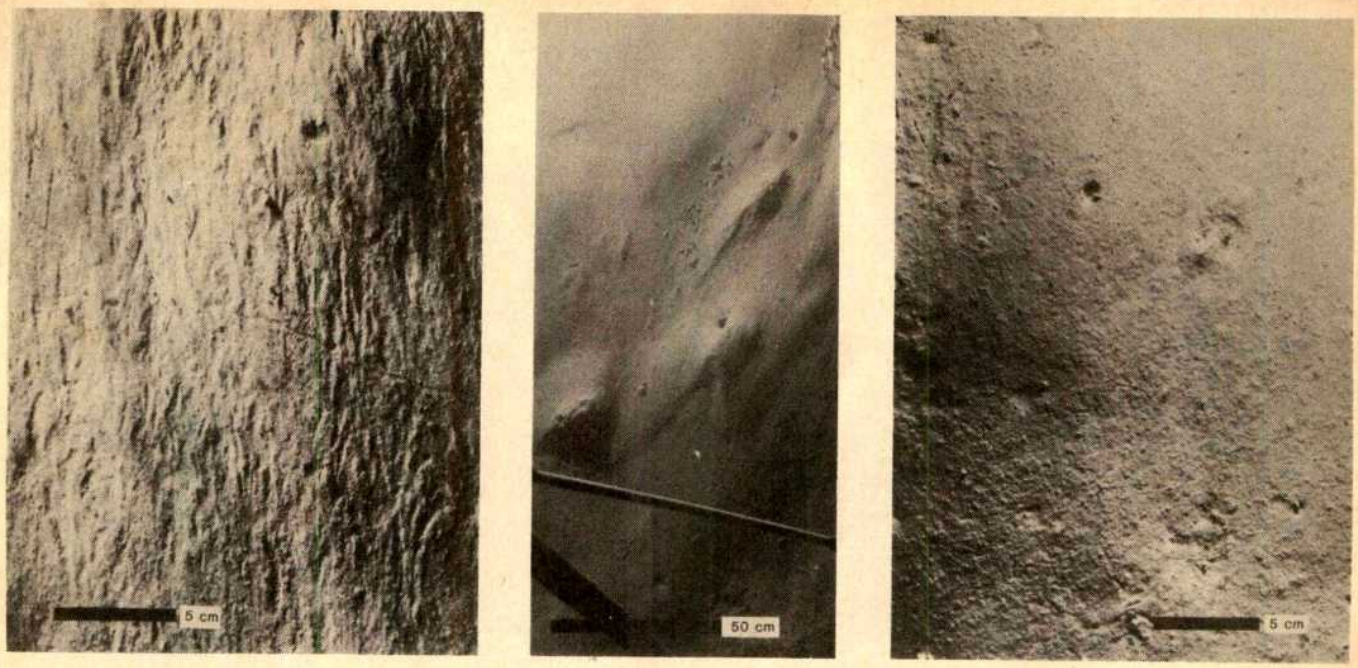

Fig. 4 Representative photographs for the conditions of: left, major erosion yielding a grooved bed (EN75); centre, deposition under a moderate current yielding barchan ripples in clayey silt (KN103); and right, tranquil conditions with a biologically textured bed and little evidence of current activity (KN96). All from the area of the HEBBLE box.

conditions are exemplified by the photographs of April and June 1983.

On the basis of the stronger bottom currents and direction reversals shown on Fig. 3 we have picked off certain times that we call 'storms'. We define as abyssal storms those periods of several days to a few weeks with intermittently high current speeds (over 0.20 m s^{-1} with peaks over 0.30 m s^{-1}) and often with reversals of current direction (see current meter records in Weatherly and Kelley[10]). Associated with this perturbation of the velocity field is high turbidity caused by resuspension of bottom sediments which some authors have termed storms[15,37]. We prefer to view the increased turbidity as a common consequence of storminess. There are about three of these storms per year occupying about 35% of the time. Less than a third of them contain speeds over 0.40 cm s^{-1} at the HEBBLE site, though they may contain such speeds somewhere in the vicinity. Nevertheless, an area can expect, on average, to suffer one of the intense scouring events like that photographed in October 1981, once per year, and be subject to a scale 2 or 3 event twice per year. The material put into suspension is deposited (or dispersed) in the remaining 65% of the time. The deposition is probably as episodic as the erosion, since concentration controls deposition rate both directly and through its control of settling velocity, thereby ensuring that initial deposition rates after storms will be fast.

The rates of deposition suggest that the upper layer 'C' of the sediment column shown in Fig. 2, 2.5–4 cm in thickness, was probably deposited between the minor storm of March 1982 and the sampling date of July 1982. The first layer 'A' probably post-dates the intense October 1981 storm, putting the mound formation in the period December to February 1982. These rates of up to a centimetre per month deposition are consistent with the ^{234}Th dating mentioned above[30,31]. The two-event signature of box core 34 (Fig. 2) is shown in at least 5 of the other 15 sub-areas of the HEBBLE box. The stratigraphy of the uppermost sediment column here is extremely ephemeral and its chance of being preserved very small. The overall Holocene deposition rate on this part of the continental rise is ~5.5 cm kyr^{-1} (giving an annual deposition/preservation ratio of 3,100), and the deposits preserved are almost totally disturbed by burrowing animals.

Driving mechanisms

The area we describe has three abyssal features possessed by several other points in the world ocean: (1) strong mean flow of 0.10–0.15 m s^{-1} (refs 10, 29); (2) high variability of flow speed and direction resulting in a high eddy kinetic energy (variance of speed)[38–40]; and (3) a large, fresh supply of mud in the form of turbidity current deposits located upstream (the Laurentian Fan). Several other sites with large supplies of mud and strong steady currents have been examined elsewhere, for example, Feni, Hatton and Gardar drifts in the northeastern Atlantic[41,42], and Blake and Greater Antilles Outer Ridge in the southwestern North Atlantic[43,44]. In none of these locations have the extraordinarily high turbidities (>1 g m^{-3}) and flow speeds attained on the Scotian Rise been matched.

The high turbidities attained must be related to high rates of erosion, as Armi[45] shows that they are not due to turbidity currents, an earlier explanation[46]. An important determinant of this is the sediment water content[47,48]. Rapidly deposited sediments have high water contents, and in the HEBBLE area the water content of the surface 2 cm ranges from >100% dry weight (>50% wet weight) to 170% (61% wet weight) (J. Y. Yingst and A. J. Silva, personal communication). This high potential erodability is a consequence of the fluctuating velocity regime, which allows rapid deposition of material under the low velocities following a storm. By contrast an area which suffers a more sustained stress may become 'stress-hardened' and more difficult to erode, requiring a large fluctuation in speed to move it[49,50]. Of course, the fact that the maximum currents here are up to 0.73 m s^{-1}, almost twice as high as those flowing over other deep-sea sedimentary bodies, also helps cause rapid erosion.

The origin of the high abyssal eddy kinetic energy in this region appears to be related to the high surface eddy kinetic energy of the Gulf Stream overhead[38–40,51,52]. However, Weatherly[39] shows that proximity of the Gulf Stream or its warm-core rings to the deep current meter locations is associated with a high frequency of current reversals (easterly flows) and with mean speeds of 0.15 to 0.20 m s^{-1} to both west and east. Rhines'[53] numerical models suggest a uniform decrease of the ratio of surface to bottom velocity with increasing E/δ where

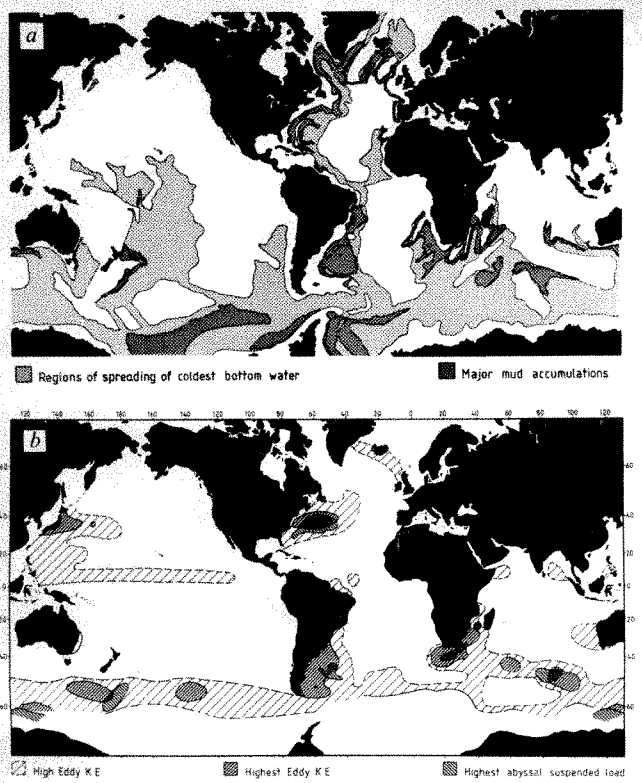

Fig. 5 *a*, Regions of spreading of cold bottom water[67] (light stipple) superimposed on distribution of large current-controlled accumulations of mud[68] (heavy stipple). *b*, Areas of high surface eddy kinetic energy or variability of surface elevation, based on Wyrtki *et al.*[71] and Cheney *et al.*[69], with, superimposed, the region of highest suspended particulate load ($>20\,g\,m^{-2}$) in the North and South Atlantic from Biscaye and Eittreim[64], the maximum turbidity in the Indian Ocean from Kolla *et al.*[65] and the turbidity high south of New Zealand from Dr P. E. Biscaye.

E is the Rossby number and δ is the relative roughness, a feature demonstrated by Dickson's results[40]. At high energy levels the eddies should be more barotropic[40] and the flow should depend only weakly on depth as shown in the Gulf Stream area by Schmitz[54]. Looking at the western Atlantic as a whole, Schmitz[38] identifies regions of deep strong mean flow as ones of enhanced eddy kinetic energy though the values are only up to half those found under the Gulf Stream.

Implications

(1) The deep-sea stratigraphical record under sites of high eddy kinetic energy is much more fragmentary than generally supposed. The situation more closely resembles storm-dominated shelf sedimentation than the continuous accumulation presumed for many parts of the deep ocean. In the Scotian Rise area the mean deposit thickness of 10^3 yr net accumulation can be removed in a few weeks and redeposited in a few months. The high nutrient flux resulting from both horizontal advection and vertical flux from the Gulf Stream's surface productivity allows intensive activity by burrowing organisms[9], yielding phenomenally high values of biological diffusivity ($3–85\,cm^2\,yr^{-1}$)[30,31] compared with previous deep-sea values (all $<0.5\,cm^2\,yr^{-1}$). Thus the signal of intermittent erosion and deposition is largely smeared out or erased once the sediments have passed below the zone of episodic erosion.

(2) This region is clearly important for generation of nepheloid layers and for their thickening by detachment and injection of turbid bottom-mixed layers to points higher up in the water column[13,16]. The high horizontal eddy kinetic energy may also be accompanied by enhanced vertical eddy kinetic energy and thus higher vertical turbulent diffusivity. It has been suggested that the cross-isopycnal diffusivity of $1–3\,cm^2\,s^{-1}$ identified by Hogg *et al.*[55] and Whitehead and Worthington[56] also results in the thickening of the nepheloid layer above the bottom-mixed layer through upwards diffusion of small particles[16,57]. A major feature of the GEOSECS suspended sediment profile down the western Atlantic is relatively high concentration extending up to a depth of 2,000 m (>2,000 m.a.b.) between 35° N and 45° N[58]. This may contain material resuspended from the bed under high eddy kinetic energy of the Gulf Stream and warm-core rings on the continental rise or cold-core rings over northern Bermuda Rise, which has been diffused upwards, as well as sediment that has spread laterally along isopycnals. Below the surface layer the small particles (mainly $<5\,\mu m$) providing most of the light-scattering signal to deep-sea nephelometers have a long residence time in suspension, probably more than a year[16,59]. Significant amounts of the optically detected material in nepheloid layers may thus have an origin in resuspension far from the detection point. This point is supported by the chemical data of Bishop and Biscaye[60], who find similarity between suspended and bed material in areas of strong currents where resuspension is likely, but some dissimilarity in quiescent regions with weak nepheloid layers. There the bottom sediment results mainly from rapid vertical flux from the surface and the nepheloid layer contributes only a slight rate of deposition. The stormy areas of the sea bed are seen as major sources of suspended material which is raised up and then advected across ocean basins. This situation is roughly analogous to that of soil aerosols, a major portion of which originate from a few areas with erodible soils and intermittently strong winds[61,62].

(3) The points of major resuspension under abyssal storms in the world ocean are likely to be those where surface eddy kinetic energy is high and coupled to a strong near-bottom mean flow and sufficient mud. An extremely dense nepheloid layer would indicate the possibility of storm activity and large sediment drifts and mud waves indicate significant long-term deposition. Several authors using the Lamont nephelometer have demonstrated a clear relationship between the regions of high mean velocity in deep boundary currents and high suspended sediment content[63–66]. Regions of spreading of coldest bottom water[67] and areas of depositional sedimentary bedforms[68] correspond closely (Fig. 5*a*). The distribution of eddy kinetic energy inferred from satellite[69,70] and ship drift observation[71] shows several areas of elevated surface eddy kinetic energy and a few particularly high spots where we presume high abyssal eddy kinetic energy. These are the North American basin under the Gulf Stream system, the Argentine basin under the confluence of the Falkland and Brazil currents, under the Kuroshio off Japan, in areas off South Africa in the Natal Valley and Mozambique Basin beneath the Agulhas current, in the Tasman Sea under the East Australian current, and over large areas beneath the Antarctic Circumpolar Current—south of the Crozet Plateau, east of the Kerguelen Plateau, in the Weddell Sea and on the southwestern side of the New Zealand Plateau (Fig. 5*b*). Many of the areas of potential bottom storminess are also the regions of maximum turbidity in the ocean basins (Fig. 5*b*). In the Atlantic the two maxima are under the Gulf Stream and in the Argentine Basin[63,64]. In the Indian Ocean maxima coincide with the Agulhas region and the area east of Kerguelen[65]. South of New Zealand along the southern end of Chatham Rise, P. Biscaye (personal communication) has located the maximum turbidity in the Pacific. The notable exception to this list is the area under the Kuroshio where no great source of suspended material has been detected[72]. The large amount of sediment eroded from Japan goes into the Japan trench and there is no strong near-bottom thermohaline flow in the region. The Pacific equatorial high surface kinetic energy does have a substantial accumulation of biogenic mud beneath it, but neither there nor in the Indian Ocean are there strong thermohaline currents along the bottom. Although only two areas under the Antarctic circumpolar current have demonstrated extremes of turbidity there is a general paucity of data from the region. It may be among the most stormy (at the bottom as well as the top) in the ocean and act as a major source of suspended material to

the abyssal thermohaline flows emanating from there and penetrating the western sides of the ocean basins.

These results drive us towards a fundamental revision of the notion that "... the warm water sphere protects and isolates the abyss from the more familiar forces of weather, leaving as the only significant dynamic factors in the nearly closed abyssal system the thermohaline currents ...' (ref. 36, p. 371).

We thank our colleagues in HEBBLE for their efforts, particularly Drs G. L. Weatherly and M. Wimbush for current meter data, Dr J. Yingst for X-radiography, Professor A. J. Silva for geotechnical data and the NCSU group for radiochemistry. Discussions with Dr W. J. Schmitz on abyssal eddy kinetic energy were very helpful, and we thank him and Weatherly for preprints of their work on abyssal kinetic energy under the Gulf Stream. This work was supported by the US Office of Naval Research under contract N00014-82C-0019 NR-083 to Woods Hole Oceanographic Institution. Woods Hole contribution 5570.

Fractal growth of copper electrodeposits

R. M. Brady & R. C. Ball

Cavendish Laboratory, University of Cambridge, Madingley Road, Cambridge CB3 0HE, UK

Black dendritic growths of copper were electrodeposited in steady-state diffusion-limited conditions onto an initially point-like cathode. Their spatial extent R *was inferred from the increased current and their mass* M *from the total charge transferred. Fractal behaviour* $M \propto R^D$ *was observed with* $D = 2.43 \pm 0.03$*, in good agreement with computer simulations of diffusion-limited aggregation.*

IF the accretion of material onto a surface is limited by diffusion onto the surface, deposition occurs preferentially on any protuberances (just as electric field lines concentrate on the convexities of a lightning conductor). In this way any initial roughness grows exponentially—the Mullins–Sekerka (MS) instability—and the deposit rapidly acquires a dendritic quality. Surface properties limit how finely ramified the deposit grows. This instability has been long recognized by materials scientists, with examples ranging from alloy solidification patterns to dendritic crystal growth (see ref. 1 for a review).

Recently, Witten and Sander[2] introduced a simple computer model in which particles diffuse onto a cluster by random walk, one at a time. This model differs from experimental systems principally by the absence of any surface tension or crystalline factors and by the very slow rate of reaction; and in this 'diffusion-limited aggregation' (DLA) model the clusters grow immediately dendritic and disorderly. They were shown to be fractal[3] in the sense that inside a large cluster the number of particles within a radius R of any given particle was on average proportional to R^D. The index D is the Hausdorff dimensionality[4] of the deposit and was found by computer simulation in three dimensions by Meakin[5] to be $D = 2.495 \pm 0.06$. Note that this model does not seem to be applicable to experiments (ref. 6 and D. Weitz, in preparation) where clustering of clusters was allowed and $D = 1.7$ obtained.

Even in the experimental systems where the MS instability is

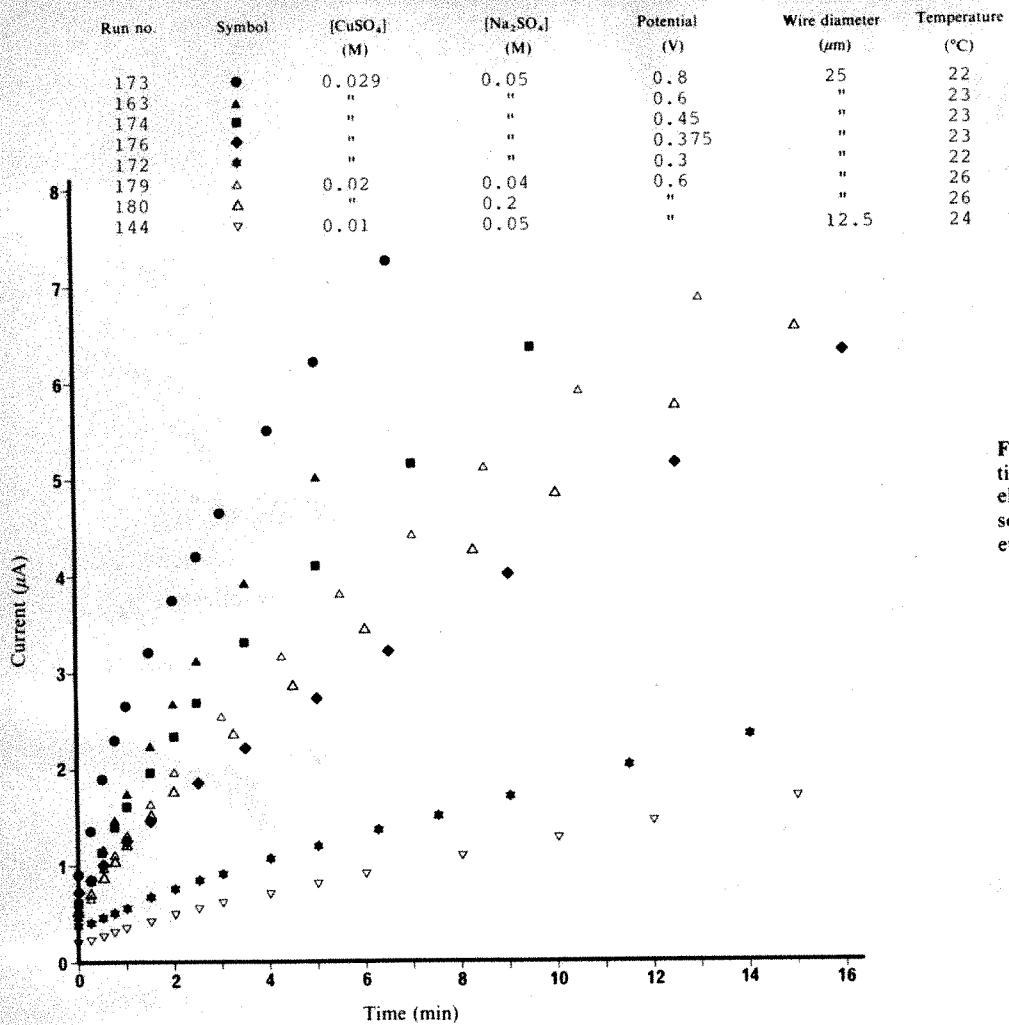

Fig. 1 Increase of current with time, for various potentials and electrolyte concentrations. All the solutions contained 1.4 wt% polyethylene oxide to impede convection.

limited by surface properties, Witten and Sander[2] suggested that weak noise should ultimately lead to disorder and similar fractal behaviour. Thus, at short length scales there may be local order due to surface tension or crystallographic factors, but at longer length scales they suggested random fluctuations should dominate: in particular, the Hausdorff dimensionality D found by computer simulation should also characterize experimental systems at long length scales.

We now report an experimental measurement of the Hausdorff dimensionality D of copper deposited electrolytically from aqueous solution in diffusion-limited conditions, onto an initially point-like cathode. The deposits were grown larger than the initial cathode but smaller than any diffusion length in the system. Because the diffusion-limited current onto such a spherical absorber is proportional to its radius (and[7] not its surface area), the instantaneous current gave an effective overall radius R_s for the deposit. With the mass M of the deposit determined from the total charge transferred, the relationship between M and R_s could then be inferred, and the fractal law $M \propto R_s^D$ verified.

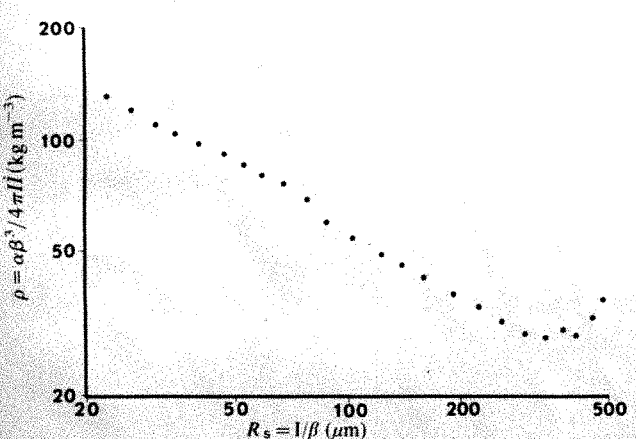

Fig. 2 Logarithmic plot of inferred density as a function of radius, for run 144.

Experiment

Solutions of copper sulphate and sodium sulphate were made up using deionized, distilled water. Polyethylene oxide $(C_2H_4O)_n$ with molecular weight 6×10^6 was added at 1.4 wt%, increasing the viscosity by a factor of 1,000 to ~1 P. The solutions were stored away from light and vigorous stirring was avoided, to prevent damage to the polymer.

In each experiment a sample of the solution was placed inside a hole of diameter 7 mm drilled in a copper block, which acted as the anode. Insulated wire of diameter 12.5 or 25 μm, the end freshly cut with a razor blade, acted as the cathode. The copper deposit would grow in a dendritic cluster around the cut end of the wire which was suspended vertically into the solution. To prevent mechanical movement during the experiment the free length of wire was kept to <7 mm, a vibration-free mounting covered with a bell-jar was used, and at least 5 min were allowed for any movement to die down before the voltage was applied.

The experiments were performed at constant voltage set in the range 0.3–0.8 V, and the current through the cell was measured as a function of time. Initially the interval between readings was 10 s, increasing to several minutes as the current rose more slowly. Typically the experiments were stopped after half an hour.

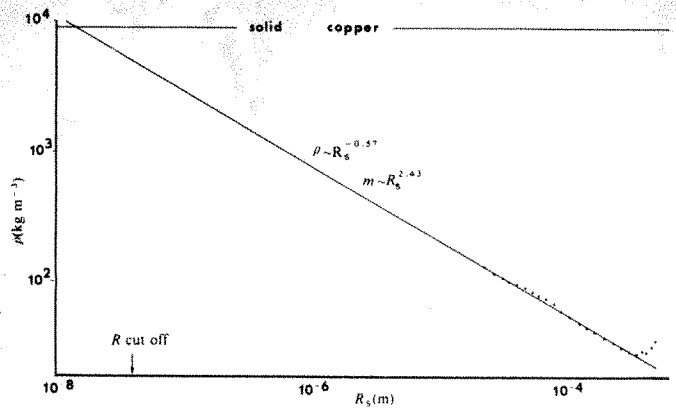

Fig. 3 The data of Fig. 2 plotted on a scale showing the density of solid copper and the radius R_{cutoff} of crystallites observed in electron micrographs. Note the extrapolation (solid line) corresponds to a Hausdorff dimensionality of 2.43.

Figure 1 shows direct plots of current I against time t for various voltages and electrolyte concentrations. It can be seen that the current grows much faster for higher voltages and higher concentrations of copper sulphate, but is relatively insensitive to the sodium sulphate concentration.

It was noted that changing the instantaneous voltage did not change the instantaneous current significantly in our experiments. Any change would have indicated that the reaction was not limited by diffusion of Cu^{2+} ions but was dominated by some other mechanism. The set voltage thus influenced the current–time curves through the morphology of the deposit and not directly through any ohmic or activation limit on the conduction.

Figure 2 shows, with interpretations discussed below, the rate of change of current dI/dt plotted as $-\log I(dI/dt)$ against $\log I$. Plotted in this way the experiment was reproducible to better than 10% except at high currents. Problems at high current and hence large radii included mechanical motion (for example, the wire bending under the weight of the deposit), stirring of the solution, and contact resistances (later improved by applying silver dag).

Results and interpretation

We define an effective radius for the deposits in terms of the diffusion-limited current. Modelling the cathode growth by a perfect spherical absorber of radius R_s, the current[7] is

$$I = \beta R_s \tag{1}$$

the coefficient β being given by

$$\beta = 4\pi KCq \tag{2}$$

where K is the diffusion coefficient, q the charge, and C the number density far from the absorber of the copper ions. This 'Smoluchovski radius' R_s characterizes where the deposition is taking place, and thus how far out the deposit extends in space. Clearly R_s will be of the same order of magnitude as the radius of gyration, R_g, measured in computer simulations[2,5]. Indeed, provided the growths are self-similar fractals as the simulations suggest, within the diffusion-limited regime the ratio R_s/R_g will be a constant independent of all parameters.

The number N of copper atoms deposited can be inferred from the charge transferred Q,

$$N = Q/q = \alpha \int I\,dt \tag{3}$$

Using equations (1)–(3), the relationship between the radius R_s and the number of atoms N can in principle be observed directly throughout the growth of the deposit. In practice the cathode was initially of finite size so that there would be an offset error in the N obtained by integration. It is to avoid this that we have instead plotted dI/dt in Fig. 2.

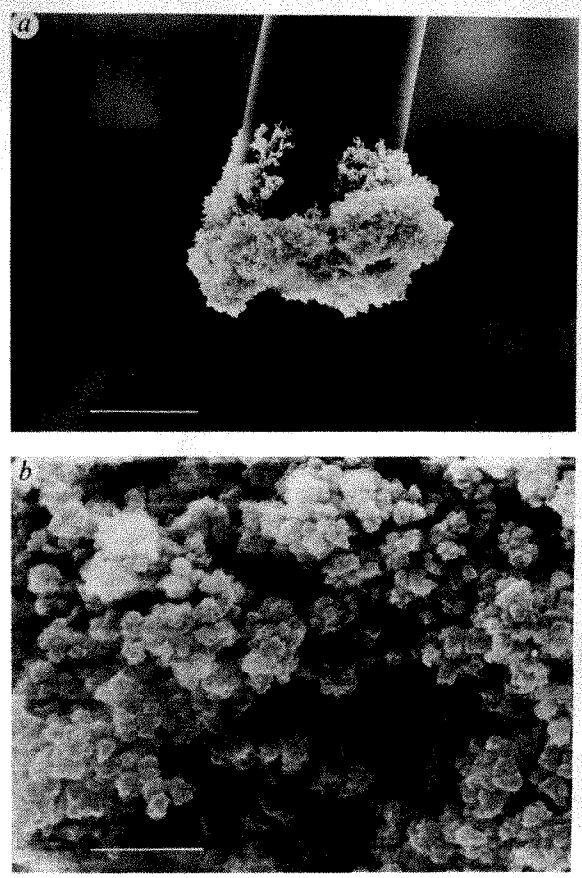

Fig. 4 Electron micrograph of a deposit grown for only 1 min in the absence of polymer. 0.01 M $CuSO_4$, 0.05 M Na_2SO_4, 0.6 V. Scale bars: *a*, 20 μm; *b*, 1 μm.

The quantity

$$\rho = \frac{\beta^3 \alpha}{4\pi I \dfrac{dI}{dt}} \tag{4}$$

may be interpreted as an effective density of deposition since, using the definition (1) above,

$$dN = 4\pi R_s^2\, dR_s \rho \tag{5}$$

Figures 2 and 3 show the density–radius plot inferred from the data shown in Fig. 1. Note the logarithmic straight line $\rho \propto R^{-0.57}$ which implies fractal behaviour, $N \propto R^D$ with $D = 2.43$. Writing this result in the form

$$\rho = \rho_{Cu}(R/a)^{D-3} \tag{6}$$

where ρ_{Cu} is the density of solid copper, the length a characterizes the onset of fractal behaviour. Extrapolating the data in Fig. 3 back to the solid copper density gives an intercept of

$$a = 14\ \text{nm} \tag{7}$$

which compares with the characteristic radius of the dendritic features seen in the electron micrographs (Fig. 4)

$$R_{cutoff} = 40\ \text{nm} \tag{8}$$

The specimen in the micrographs was produced in similar conditions, except that it was grown for only 1 min and with no polymer present so as to minimize damage on removal from the solution.

The experiment was repeated at various electrolyte concentrations as listed in Table 1 together with the Hausdorff dimensionalities D obtained. The values of D show no evidence of systematic variation and taken together give

$$D_{\text{experiment}} = 2.43 \pm 0.03 \quad (9)$$

which compares with the result from DLA computer simulations[5]

$$D_{\text{DLA simulation}} = 2.495 \pm 0.06 \quad (10)$$

For each run the intercept a was extrapolated using the value $D = 2.43$, and Fig. 5 shows how the reciprocal radius $1/a$ varied with the voltage of the experiment. We have no explanation for the apparent law,

$$1/a \propto V - (0.23\ \text{V}) \quad (11)$$

Note that the intercept a in Fig. 5 does not depend on the concentration of copper sulphate.

Electrochemical considerations

Our interpretation of the experiment presupposes that the net reaction at each electrode was

$$Cu^{2+}(aq) + 2e^- \rightleftharpoons Cu(s) \quad (12)$$

and that the reaction was limited by diffusion of Cu^{2+} ions in the vicinity of the cathode.

To evolve hydrogen gas at the cathode in the principal experimental conditions (0.01 M $CuSO_4$, 0.05 M Na_2SO_4, neutral pH) requires at least 0.685 V (ref. 8). Below this limit there are no anion oxidations available, and the only remaining chemical difficulty is the role of singly charged Cu^+ ions. In experimental conditions there is an equilibrium ratio in the presence of copper (see ref. 8),

$$[Cu^+]/[Cu^{2+}] = 7 \times 10^{-3}\ (25\ ^\circ\text{C}, 0.01\,\text{M}\ Cu^{2+}) \quad (13)$$

and such a concentration of Cu^+ is soluble. With the anode working at low current density (of the order of 1 μA cm^{-2}), we presume that this equilibrium was maintained and therefore that the current due to Cu^+ ions was negligible.

If stirring of the solution is prevented, the electric fields will be screened and deposition will be limited by diffusion in the neighbourhood of the cathode. The calculated Debye–Huckel screening length for 0.05 M sodium sulphate is $\lambda = 1$ nm. (There is in fact a small unscreened voltage of the order of

$$V = kT/e([Cu^{2+}]_{\text{bulk}} - [Cu^{2+}])/[Na_2SO_4] = 5\ \text{mV} \quad (14)$$

required to maintain neutral charge density as the Cu^{2+} ions adopt a density profile governed by diffusion kinetics.)

Data from the Smithsonian Tables[9] indicate an ionic diffusion constant for aqueous Cu^{2+} at 24 °C of $K = 6.17 \times 10^{-10}$ m^2 s^{-1}, with a temperature coefficient of 0.0229 K^{-1}. This implies a value for our parameter β (equation (1)) of

$$\beta = 0.0121 \quad \text{A m}^{-1}\ (\pm 5\%) \quad (15)$$

We assume that the polymer had little effect so that the main error in the value for β was the use of dilute solution approximations.

Diffusion lengths

The assumption of Smoluchovski kinetics (equations (1), (2)) requires that the cathode radius R is less than any intrinsic diffusion lengths limiting the scope of a laplace equation for $[Cu^{2+}]$.

The rate at which the diffusant concentration can relax determines a diffusion length $\xi_t = \sqrt{Kt}$. From equations (1)–(4) the dimensionless ratio $\gamma_t = R/\xi_t$ is of the order of

$$\gamma_t = \sqrt{C/\rho} \quad (16)$$

reaching a maximum value of 0.1 for the largest deposits grown (see Fig. 3) with a concentration of copper suphate $C = 0.01$ M.

The fluid close to the cathode is depleted of copper ions and is thus less dense by about 2% than the surrounding fluid in

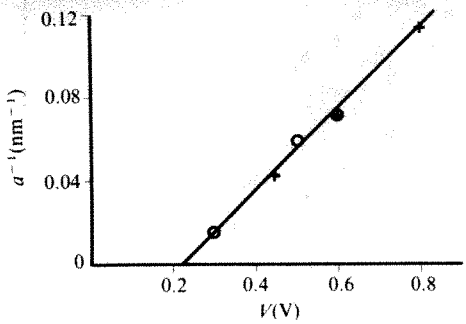

Fig. 5 Variation with voltage of intercept radius a. 0.05 M Na_2SO_4, 1.4 wt% polyethylene oxide. Concentration of copper sulphate (redetermined by solution conductivity): +, 0.029 M; ○, 0.01 M.

Table 1 Fractal dimension of copper electrodeposited from solution at 0.6 V

180	0.02	0.2	2.41
Mean dimension			2.433 ± 0.03
Computer prediction[5]			2.495 ± 0.06

The solutions contained 1.4 wt% polyethylene oxide to increase viscosity.

experimental conditions. Comparing the resulting flux due to convection with that due to diffusion gives a dimensionless parameter

$$\gamma_c = R/\xi_c = mgCR^3/\eta K \quad (17)$$

where mg is the weight of a copper ion and η is the viscosity of the solution. This gives a room temperature value $\gamma_c = 0.02$ for twice the radius of the thinnest wire used ($R = 25$ μm) if no polymer is added. Because $\gamma_c \propto R^3$ this would leave less than one decade of radius before convection became important.

The addition of 1.4 wt% polyethylene oxide raised the overall viscosity by a factor of ~1,000 without significantly affecting the diffusion of small inorganic ions. The range of diffusion-limited behaviour is thus extended in radius by an order of magnitude and the damping of mechanical disturbances also improved.

Conclusions

The two principal conclusions are that the electrolytic deposit of copper in experimental, diffusion-limited conditions is fractal, and that the Hausdorff dimensionality agrees closely with the simple computer model of diffusion-limited aggregation[2,5]. This is the first experimental verification of the conjecture by Witten and Sander that such fractal behaviour should occur at long length scales irrespective of local details. The experimental deposits were highly ordered up to order 40 nm, but the Hausdorff dimensionality was measured over the range 25–400 μm. Extrapolating the experimental data and comparing with electron micrograph observations suggests that in fact the fractal behaviour extends over the full range 40–400,000 nm.

There are several possible sources of systematic error in the present experiment. Convection, agitation, contact resistance and resistance and rigidity of the deposit were all problems that we believe were brought under control. Other possible problems

include non-inertness of the polymer, and the presence of any surface-active impurities.

In future work there are four aspects of the experiment which could be improved or varied: the type of measurement made; the electrolyte solution; the geometry; and the physical regime.

That the surface area of the deposit is proportional to its mass could be verified by measuring the capacitance. If the screening length in the solution is short and resistances can be rendered small or corrected for, the capacitance should be proportional to surface area.

The complications associated with the two possible oxidation states of copper might be avoided by, for example, the use of silver electrolytes. Convection might be suppressed without resort to polymer by the use of aqueous Ni^{2+} in the presence of excess CsCl: with these species there is the possibility of arranging that there be no net density change of the solution near the cathode. Other viscosity enhancers might also be tried.

It might be possible to make measurements in a two-dimensional geometry by, for example, using filter paper soaked in the electrolyte. In three-dimensional experiments, the use of microelectrodes would allow measurements to be made down to smaller length scales, but there could be mechanical problems with such an arrangement. A novel and more stable geometry would be to grow from a 'pinprick' (perhaps made by a spark) in the insulation on a plate: it would be useful to perform the corresponding computer simulation for growth from a point seed into the half space above a plane.

In our experiments the deposits grew slowly compared with the diffusion of ions. It should be possible by using higher electrolyte concentrations to explore the region where the deposits grow more quickly and behaviour is controlled by the diffusion length[1,10]. An alternative regime leading to fractal deposition might be obtained by stirring the solution until the reaction becomes limited not by diffusion but by ohmic resistance. It would then be the equations of electrostatics which drive the MS instability at long length scales.

R.C.B. and R.M.B. acknowledge Research Fellowships from Gonville and Caius College and from Trinity College, Cambridge respectively. We also thank Union Carbide Ltd for supplying their WSR 301 Polyox, the polymer used in our experiments. Finally we thank Drs J. Agar, M. Archer, J. Deutsch and P. Luckham for valuable advice and discussions.

Two protein-binding sites in chromatin implicated in the activation of heat-shock genes

Carl Wu

Laboratory of Biochemistry, Developmental Biochemistry Section, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

The resistance to exonuclease digestion of two regions of chromatin at the 5′ end of heat-shock genes in Drosophila *implies they have protein bound to them. The pattern of resistance before and after induction of gene expression suggests that heat-shock genes are activated by the sequential binding of at least two protein factors.*

THE continuous array of nucleosomes along the eukaryotic chromatin fibre is punctuated by local discontinuities which are hypersensitive to endonuclease attack. Discovered originally at the origin of replication in the simian virus 40 (SV40) minichromosome[1–4] and in cellular chromatin encompassing the 5′ end of several *Drosophila* heat-shock genes[5,6], nuclease hypersensitive sites spanning about 100–300 bp of DNA in chromatin have since been widely observed (see refs 7, 8 for recent reviews). Usually, but not always, the hypersensitive sites are located near the 5′ end of genes. Their appearance precedes the onset of transcription and is also tissue- or stage-specific in developmentally regulated genes. The extreme susceptibility to nuclease attack is generally considered to indicate a local opening in chromatin for regulatory proteins and enzymes to enter and bind to target DNA sequences.

I have developed an *in situ* exonuclease III (Exo III) protection technique which maps sequences within nuclease hypersensitive sites in chromatin onto which regulatory proteins might be bound. Short stretches of DNA amidst the 5′ hypersensitive sites of the genes for the heat-shock proteins of molecular weight 83,000 and 70,000 (hsp83, hsp70) in *Drosophila* are indeed found to be resistant to exonuclease digestion. The resistant regions cover the TATA box sequence and an upstream control element.

5′ hypersensitivity of the hsp70 gene

Hsp70 is the most abundant of the small group of proteins inducible in *Drosophila* and other organisms by heat shock or other environmental stress[9]. There are five copies of the uninterrupted 2.2 kilobase pair (kb) hsp70 coding sequence, located at two chromosomal loci, 87A and 87C. The hsp70-coding region and about 350 base pairs (bp) of 5′ flanking sequences are highly conserved among all five genes[9–11].

Fine-structure analysis of the DNase I hypersensitive site at the 5′ end of the hsp70 gene gives an initial hint for a resistant region buried within. Nuclear chromatin from noninduced *Drosophila* cells (Schneider line 2, SL2) is digested gently with DNase I. After purification, the DNA is cleaved with a restriction enzyme, *Bam*HI, electrophoresed on a long agarose gel, blotted to nitrocellulose, and hybridized to a ^{32}P-labelled, probe segment chosen to abut the common *Bam*HI site at position +1,262 in the hsp70 gene sequence; +1 is the transcriptional start (Fig. 1). This effectively labels subfragments extending from that restriction site to the DNase I break made in the initial digestion;

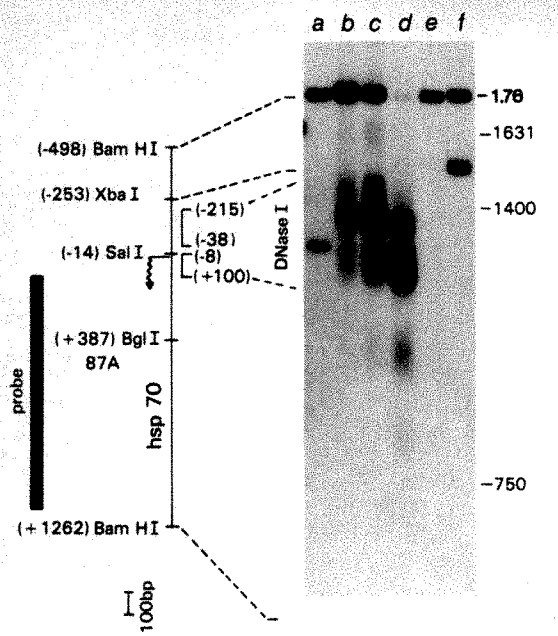

Fig. 1 DNase I hypersensitivity at the 5′ end of the noninduced hsp70 gene. A partial restriction map of one of the two hsp70 genes at chromosomal locus 87A is shown[11]. The start site (+1) and direction of transcription is indicated by the arrow.
Methods: Nuclei from *Drosophila* SL2 cells were isolated and digested with DNase I at 6, 8 and 4 U ml^{-1} (a separate reaction) respectively as described previously[5] (lanes *b–d*). Purified DNA (10 μg per lane) was restricted with *Bam*HI, electrophoresed on a 40 cm long, 1.4% agarose Tris-acetate EDTA (TAE) gel, blotted, hybridized to a ^{32}P-labelled, cloned probe fragment (solid bar) and autoradiographed as described previously[5]. For markers, SL2 DNA was restricted partially with *Sal*I, *Bam*HI and *Xba*I respectively, followed by complete *Bam*HI restriction and processing as above (lanes *a*, *e*, *f*).

thus the DNase I break points can be positioned by simple length measurement (the indirect end-labelling method)[5,12]. The probe used detects the *Bam*HI fragments and cleaved subfragments from all five hsp70 genes, although only the 1.76-kb *Bam*HI fragment corresponding to one gene is included in Fig. 1; the larger *Bam*HI fragments have been cropped away[5]. As noted before, the DNase I cleavages in chromatin span a broad region around the 5′ end of the hsp70 gene, although some suppression and enhancement is now clearly evident (lanes *b–d*). For precise mapping, genomic DNA restricted additionally at landmark sites are electrophoresed in adjacent lanes (lanes *a*, *f*), or are co-electrophoresed with the samples (data not shown). Thus the hsp70 sequences hypersensitive to DNase I in chromatin extend from positions +100 to −8 and from −38 to −215, with a peak at −93. The 30-bp region in between, from −8 to −38, is relatively resistant. These measurements are precise to 5–10 bp. The complex digestion pattern could be due to different contributions from each of the five hsp70 genes. However, it is qualitatively unchanged when the genes at either chromosomal locus are removed with specific restriction cleavage (data not shown); thus the average pattern is likely to represent each hsp70 gene. The site from −8 to −38 that is resistant to partial cleavage suggests bound nonhistone protein. For more conclusive evidence, a new test has been devised which can visualize the resistant fragments positively after limit nuclease digestion.

Mapping Exo III-resistant sites

One way to locate the borders of protein-bound sites on a piece of DNA is to nibble in from either end with an exonuclease, usually *Escherichia coli* exonuclease III[13], until further passage of the enzyme is blocked, and to measure the length of the resistant DNA strand in such a limit digest. This approach was used successfully to localize protein-binding sites in reconstituted complexes of DNA with purified *E. coli* RNA polymerase, λ integrase and SV40 T antigen, and to analyse the disposition of DNA in native and reconstituted nucleosomes[14–26]. Here I combine the use of Exo III with the indirect end-labelling method to detect the presence of specific barriers against Exo III digestion in chromatin.

As Fig. 2*A* shows, an initial cut is made within a hypersensitive site by a (partial) endonuclease reaction on isolated nuclei. This creates a free end from which Exo III can digest 3′ to 5′ along the DNA until a specific block is encountered in the limit. The DNA is purified and the single-stranded tails are trimmed with S_1 nuclease. After further cleavage with flanking restriction enzymes it is possible to determine the relative start and stop positions of Exo III by indirect end-labelling the subfragments produced from endo- and exonucleolytic cleavages.

For the noninduced hsp70 gene, the initial cuts can be made by each of four different endonucleases: DNase I, micrococcal nuclease, a Ca^{2+}–Mg^{2+} stimulated endogenous nuclease, and a restriction enzyme *Xho*I which cleaves at position −194, inside the distal boundary of the DNase I hypersensitive site (Fig. 2*B*). Exo III is added in increasing amounts simultaneously except for micrococcal nuclease, which is inactivated with EGTA without affecting Exo III added subsequently. The purified and S_1-trimmed DNA is restricted with *Bam*HI and *Xba*I, and the relative positions of the endo- and exonuclease cleavages are located by indirect end-labelling.

The complex pattern of 5′ hypersensitivity is again observed when only the initial cuts are made with no added Exo III (Fig. 2*B*, lanes *b*, *j*). However, with the introduction of Exo III, the fragments upstream of the 30-bp, resistant site coalesce sharply to a discrete position on its distal edge, no matter which enzyme is used to make the initial cut. The discrete barrier clearly persists even when Exo III activity is increased roughly 100-fold (lane *i*). When the first cut is made by *Xho*I at position −194, Exo III nibbles almost quantitatively from that site to the same discrete stop. The distance travelled by Exo III from the *Xho*I site can be determined precisely (to within 5 bp) by measuring the relative difference in fragment lengths between the two subfragments, using DNA markers in adjacent gel lanes, or mixed in together with the samples (see Fig. 3). Thus the block in the noninduced hsp70 gene is located at position −40.

No Exo III resistance on protein-free DNA

Two potential artefacts can compromise the technique. The discrete block observed could be due to a specific cut made by S_1 nuclease on the purified DNA during the trimming step, or to a peculiar DNA sequence which blocks the passage of the enzyme by virtue of primary or secondary DNA structure alone. In a control experiment using protein-free DNA as substrate (Fig. 2*C*), no specific cuts are shown to be made by S_1 nuclease on free DNA at the position of blockage in chromatin, nor at any other position in the region analysed (lane *c*). Also, no impediments against Exo III digestion due to the DNA sequence alone are observed (lane *d*). Hence, the resistance to Exo III digestion is due to nucleoprotein structure in chromatin.

Heat shock

Does the pattern of Exo III digestion from the *Xho* I cut at −194 change during heat shock? Although the efficiency of restriction is somewhat reduced in the induced hsp70 gene, the digestion pattern is qualitatively different from the noninduced pattern (Fig. 3). Instead of a discrete stop at −40, the enzyme stutters from position −108 to −40, indicating that a comparatively weak barrier (or series of barriers) is encountered, starting at −108. The different patterns of resistance in the normal and the induced genes are found to be similar at both chromosomal loci, using additional restriction cleavage which effectively removes the genes at either locus (data not shown); thus the average pattern is likely to represent each individual hsp70 gene.

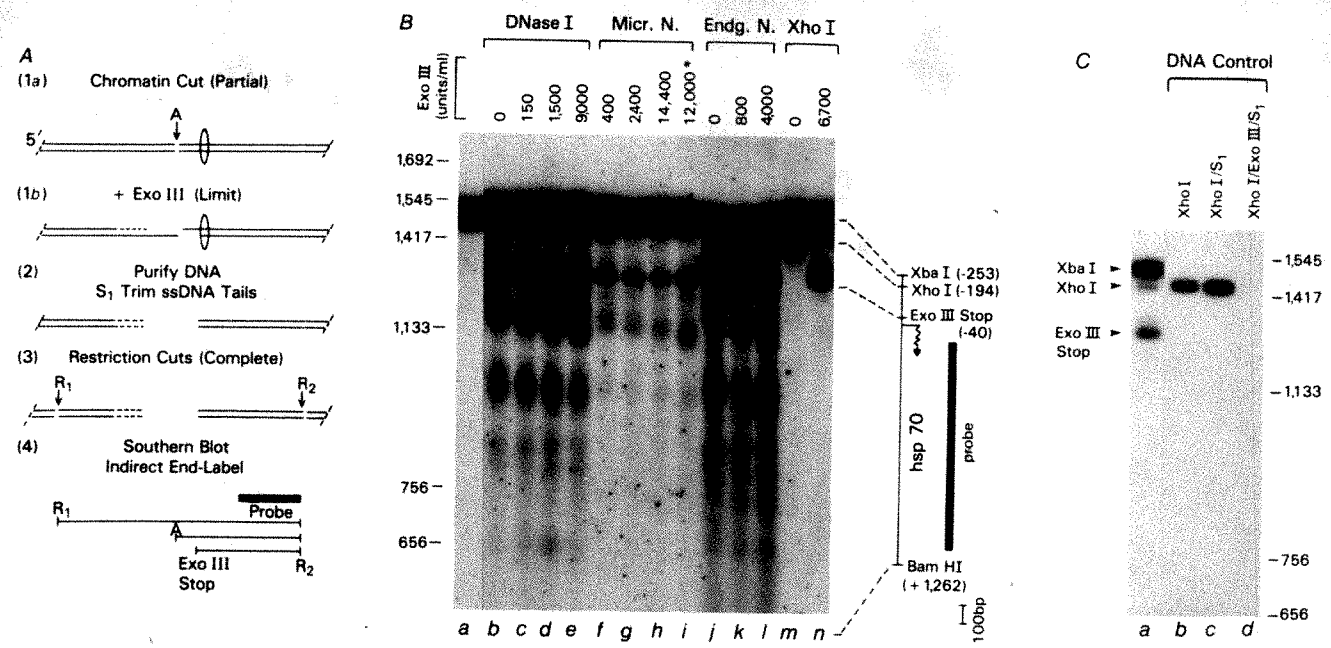

Fig. 2 ***A***, The Exo III protection technique. A hypersensitive site in chromatin is drawn as a region of DNA with a hypothetical protein bound to it. ***B***, Exo III resistance in chromatin in the noninduced hsp70 gene. A partial restriction map of the hsp70 gene is shown[11]. Lane *a*, No enzyme control. SL2 nuclei were mock-incubated in digestion buffer. Lanes *b–e*, SL2 nuclei were digested with DNase I, 10 U ml^{-1} and Exo III for 11 min at 30 °C. Lanes *f–i*, 0–18 h embryonic nuclei were digested with micrococcal nuclease, 9 U ml^{-1}, 3 min, 25 °C. The enzyme was inactivated with EGTA to 0.5 mM, Exo III was introduced and the digestion continued at 30 °C for 7 min (lanes *f–h*) or for 30 min (lane *i*)*. Lanes *j-l*, SL2 nuclei were digested with an endogenous nuclease stimulated by digestion in buffer plus 1 mM $CaCl_2$, at 37 °C for 10 min. $CaCl_2$ was chelated with EGTA to 1.5 mM, Exo III was added and digestion continued at 37 °C for 15 min. Lanes *m*, *n*, SL2 nuclei were digested with *Xho*I at 2,000 U ml^{-1} and Exo III for 10 min, 30 °C. ***C***, S_1 nuclease and Exo III reactions on protein-free DNA.
Methods: ***B***, Isolation of nuclei: SL2 cells were disrupted at 0–4 °C in a Dounce homogenizer in nuclear buffer (60 mM KCl, 15 mM NaCl, 5 mM $MgCl_2$, 0.1 mM EGTA, 15 mM Tris-HCl *p*H 7.4, 0.5 mM dithiothreitol (DTT), 0.1 mM phenylmethylsulphonyl fluoride (PMSF), 0.3 M sucrose). Unbroken cells were pelleted at 1,600*g* for 45 s. The supernatant was centrifuged through 1 vol of nuclear buffer–1.7 M sucrose (stirred interface), at 17,000*g* (average) for 15 min in a swinging bucket rotor. Purified nuclei were resuspended for digestion in nuclear buffer–5% glycerol at 5×10^8 nuclei ml^{-1}. Nuclei from *Drosophila melanogaster* embryos (Oregon R, P2 strain) were prepared after dechorionating in 50% Chlorox, 0.02% Triton X-100 for 3 min at room temperature, by disruption in a Dounce homogenizer in nuclear buffer at 0–4 °C. The homogenate was filtered through a crude paper filter and the filtrate was centrifuged at 1,600*g* for 90 s. The supernatant was centrifuged at 3,700*g* (average) for 5 min in a swinging bucket rotor to pellet crude nuclei. The pellet was resuspended in nuclear buffer, and further centrifuged through nuclear buffer–1.7 M sucrose as above. Purified embryonic nuclei were resuspended for digestion in nuclear buffer–5% glycerol at 1×10^9 nuclei ml^{-1}. Nuclease digestion: Nuclear buffer–5% glycerol was used as the standard buffer for all digestions except those involving micrococcal nuclease, which included 0.4 mM $CaCl_2$. Nuclei were digested with the primary cleavage enzyme plus Exo III (New England Biolabs or Boehringer Mannheim). Digestions were terminated as described previously[5] and nucleic acids were purified by overnight proteinase K digestion, 50 μg ml^{-1}, 37 °C, and by repeated organic extractions followed by ethanol precipitation[6]. S_1 nuclease trimming: Reactions were performed in 40 mM NaOAc, *p*H 4.5, 1 mM $ZnSO_4$ and 250 mM NaCl using 4,000 U ml^{-1} S_1 nuclease (Boehringer Mannheim) at 30 °C for 15 min. The DNA concentration was typically ~0.2 mg ml^{-1}. The reaction was terminated by the addition of EDTA to 5 mM and Tris-HCl *p*H 8.0 to 50 mM. Nucleic acids were purified by organic extraction and ethanol precipitation. Restriction digests and gel electrophoresis: DNA samples (~ 5 μg per lane) were secondarily restricted to completion using *Bam*HI + *Xba*I, together with a trace of RNase A and RNase T1. DNA was electrophoresed on a 40 cm long, 1.4% agarose TAE gel at room temperature for ~35 h. The gel was treated in 0.1 M HCl for 15 min before the DNA was denatured, neutralized and blotted, as described previously[5] except that the blotting solution was 20x SSC, 1 M NH_4OA_c (1x SSC is 0.15 M NaCl, 0.015 M Na citrate *p*H 7.0). The filter was rinsed in 1/2 × blotting solution, dried, baked, prehybridized for 4–8 h at 65 °C and hybridized as described previously[5] without dextran sulphate for 12 h at 65 °C in a slit chamber to a recombinant plasmid labelled with ^{32}P by nick-translation to a specific activity of $\sim4\times10^8$ c.p.m. per μg DNA. The solid bar indicates the region of the hsp70 gene in the plasmid. The filter was washed twice at 65 °C in 2 × SSC, 0.5% SDS and three times in 0.1 × SSC, 0.1% SDS, 65 °C; each wash was for 15 min with agitation. The filter was exposed without intensification. ***C***, 20 μg purified SL2 DNA was restricted with *Xho*I in 25 μl of 100 mM NaCl, 6 mM $MgCl_2$, 10 mM Tris *p*H 7.4. After the reaction 25 μl of nuclear buffer was added and 5 μl of the mixture was removed for secondary *Bam*HI restriction (lane *b*). Lane *c*, DNA was purified by phenol extraction from 22.5 μl mixture. The phenol was removed by ether extraction, the DNA treated with 2,500 U ml^{-1} S_1 nuclease as in Fig. 2*b* legend, purified, and digested with *Bam*HI. Lane *d*, the last 22.5 μl of mixture were digested with 4,000 U ml^{-1} Exo III at 30 °C for 10 min. DNA was purified, S_1 trimmed, repurified and restricted with *Bam*HI. Samples *b–d* were electrophoresed, blotted and hybridized to hsp70 probe as in *B* legend, along with a typical *Xho*I + Exo III reaction on chromatin for comparison (lane *a*).

Other side of barrier

The other side of the barrier to Exo III in the normal and induced hsp70 genes is mapped using *Pvu*II to make the initial cut; the enzyme cleaves at position +65, inside the proximal boundary of the DNase I hypersensitive site (Fig. 4). The hybridization probe labels the 3.56-kb fragment containing one hsp70 gene, but is also weakly homologous to other *Bgl*II fragments; these do not obscure the analysis of the hsp70 subfragments. In both normal and induced samples, a discrete barrier which maps to position −12 is observed (Fig. 4, lanes *c, d, f, g*). A control experiment using protein-free DNA as substrate indicates that this barrier is due neither to artefactual S_1 cleavage nor to the DNA sequence alone (data not shown).

An endogenous exonuclease activity is also observed here, in the reactions without Exo III, but this activity is blocked at essentially the same position (Fig. 4, lanes *b, e*). Taking into account the uneven amounts of DNA loaded, proportionately more of the *Bgl*II–*Pvu*II fragment is chased into the subfragment, by addition of Exo III. The endogenous activity nibbles predominantly in a single-stranded manner since *Pvu*II restriction of chromatin without subsequent S_1 nuclease reaction gives a fragment which co-migrates with a whole *Bgl*II-*Pvu*II fragment (lane *a*). As expected from previous work[27], the sensitivity of a *Pvu*II site at +1,034 in the hsp70-coding region is increased during induction, but no discrete subfragments due to exonuclease activity emerge from this site.

In summary, convergent Exo III digestion from cuts on each flank of the DNase I hypersensitive site reveals strong blockage at positions −40 and −12 respectively, and delimits a 28-bp, resistant site (site I) for the noninduced hsp70 gene. This agrees well with the earlier mapping of the 30-bp, DNase I resistant site from −38 to −8. For the induced hsp70 gene, strong blockage again at −12 suggests retention of site I. In addition, the diffuse blocks from −108 to −40 reveal a new site of weaker resistance (site II), the distal border of which lies at −108; its proximal border cannot be mapped from the other side because the enzyme is unable to penetrate site I.

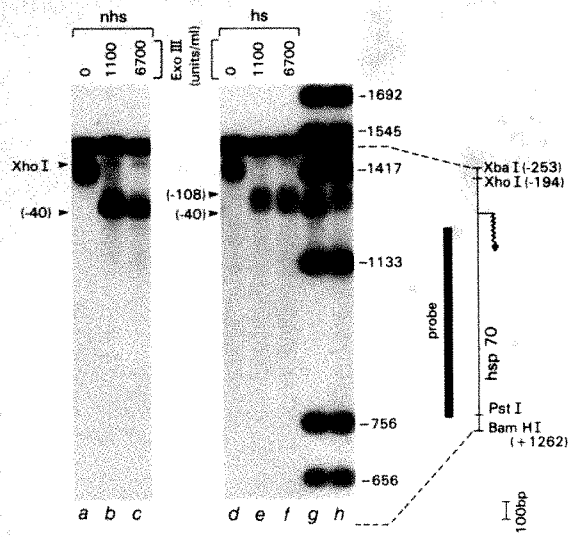

Fig. 3 Exo III digestion from the *Xho*I cut at position −194 in normal and induced hsp70 gene chromatin. Isolated nuclei from 0–18 h old, nonshocked embryos (lanes *a-c*) and from embryos heat-shocked for 15 min at 36 °C (lanes *d–f*), were digested for 10 min at 30 °C with *Xho*I at 2,000 U ml^{-1} plus Exo III as indicated. Purified DNA samples were digested with S_1 nuclease, restricted secondarily with *Bam*HI + *Xba*I, electrophoresed, blotted and hybridized with the hsp70 gene probe as described in Fig. 2*B* legend. The Exo III stop positions in base pairs upstream from the mRNA start (+1) are indicated beside the arrowheads. Lanes *g* and *h* are the same samples as in *b* and *e* spiked with pBR322 marker fragments, ~60 pg each (pBR322 restricted with *Bam*/*Pvu*II; *Bam*/*Pst*; EcoRI/*Sal*I/*Pvu*II/*Pst*I).

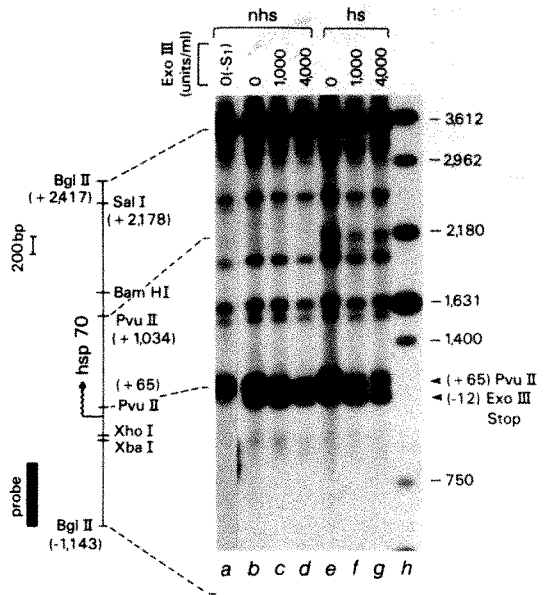

Fig. 4 Exo III digestion from the *Pvu*II cut at position +65 in normal and induced hsp70 gene chromatin. A partial restriction map of the first of the two hsp70 genes in tandem at chromosomal locus 87C is shown[11]. Isolated nuclei from nonshocked SL2 cells (lanes *b–d*) and from cells heat shocked for 15 min at 36 °C (lanes *e–g*) were digested for 40 min at 37 °C with 600 U ml^{-1} *Pvu*II plus Exo III as indicated. DNA was purified, trimmed with S_1 nuclease, repurified, restricted with *Bgl*II, electrophoresed on a 30 cm 1.2% agarose gel, blotted and hybridized with the cloned probe (solid bar) as described in Fig. 2*B* legend. An arrowhead indicates the Exo III (and endogenous nuclease) stop position. Similar results are obtained using normal and heat-shocked embryos. Lane *a* is a *Pvu*II digest of nonshocked SL2 nuclei at 400 U ml^{-1}, 30 °C, 20 min; the purified DNA was restricted with *Bgl*II without prior S_1-nuclease treatment, and processed as above. Lane *h* contains pBR322 markers as in ref. 5.

Exo III resistance on hsp83 gene

The single-copy gene encoding hsp83 resides at chromosomal locus 63BC and consists of a 3.7-kb transcription unit containing two exons separated by a 1.1-kb intron[28–31]. I have previously mapped a cluster of three DNase I hypersensitive sites, one of which encompasses the 5′ terminus of the hsp83 gene[5]. The Exo III digestion pattern from a *Eco*RI cut at position −166 is shown in Fig. 5*A*. In noninduced *Drosophila* embryos, the principal subfragment among the heterogenous collection produced by the endogenous exonuclease and by Exo III locates a barrier at position −39 (Fig. 5*A*, lanes *b*, *c*). On heat induction, this barrier shifts sharply to position −86 (lanes *d*, *e*).

The other side of the barriers are located by using exonuclease to nibble upstream from a *Rsa*I cut at position +20 (Fig. 5*B*). In noninduced *Drosophila* embryos, the principal subfragment produced by the endogenous exonuclease locates a weak barrier at position −17 (Fig. 5*B*, lanes *b*, *c*). Addition of Exo III further degrades that subfragment; there is a minor pause at −61 (lanes d, e). In heat-shocked embryos, two sharply discrete subfragments, one chasing into the other, are produced by the endogenous exonuclease and by Exo III (Fig. 5*B*, lanes *f*, *g*, *h*, *i*), locating two barriers at positions −17 and −50 respectively. No resistant sites are found in the controls using free DNA (data not shown). The relatively lower yield of cleaved subfragments in noninduced samples in Fig. 5 is primarily due to a less efficient initial restriction cut.

In summary, the resistance to convergent exonuclease digestion at −39 and −17 delimits a relatively weak, 22-bp resistant site (site I) for the noninduced hsp83 gene. For the induced gene, blockage again at −17 suggests the retention of site I. In addition, a 36-bp resistant site from −86 to −50 is revealed (site II). The distal border of site I cannot be mapped here because exonuclease is unable to penetrate site II. No highly resistant sites are found within the other two DNase I hypersensitive sites clustered near the 5′ end of the hsp83 gene (data not shown).

TATA and upstream sequences

The resistant sites are aligned over the nucleotide sequences[29] upstream of the hsp83 and hsp70 transcriptional starts in Fig. 6*A*. They lie within the 5′ flanking region involved in the regulation of these genes[32–36]. Strikingly, for both hsp83 and hsp70 genes, site I surrounds the TATA box sequence which is indispensable for accurate transcriptional starts[37]. For the induced hsp83 gene, site II covers the upstream consensus sequence CTNGAANNTTCNAG that is required for heat-inducible expression in heterologous transient assays[33,35]. This upstream element is also contained within the more diffuse site II in the induced hsp70 gene, although the site does extend an additional 45 bp upstream. Curiously, site I is strong in the hsp70 gene whereas site II is strong in the hsp83 gene.

Site II does directly cover the consensus sequence in the induced hsp83 gene. Before induction, two *Xba*I sites at −74 and −64, essentially coincident with the upstream element, are hypersensitive to *Xba*I cleavage in chromatin when compared with a site at +484 within the hsp83 transcription unit. After induction, the upstream *Xba*I sites are almost totally resistant, whereas the latter is more sensitive (Fig. 5*B*, lanes *j*, *k*). A rough analysis (not shown) indicates that sites I and II in the hsp83 gene are also resistant to DNase I digestion.

Discussion

The resistant sites surrounding the TATA box sequence and the upstream control element cover 22 bp or 28 bp and 36 or <68 bp respectively, depending on the gene. This range is considerably less than the 146 bp of DNA resistant to enzyme

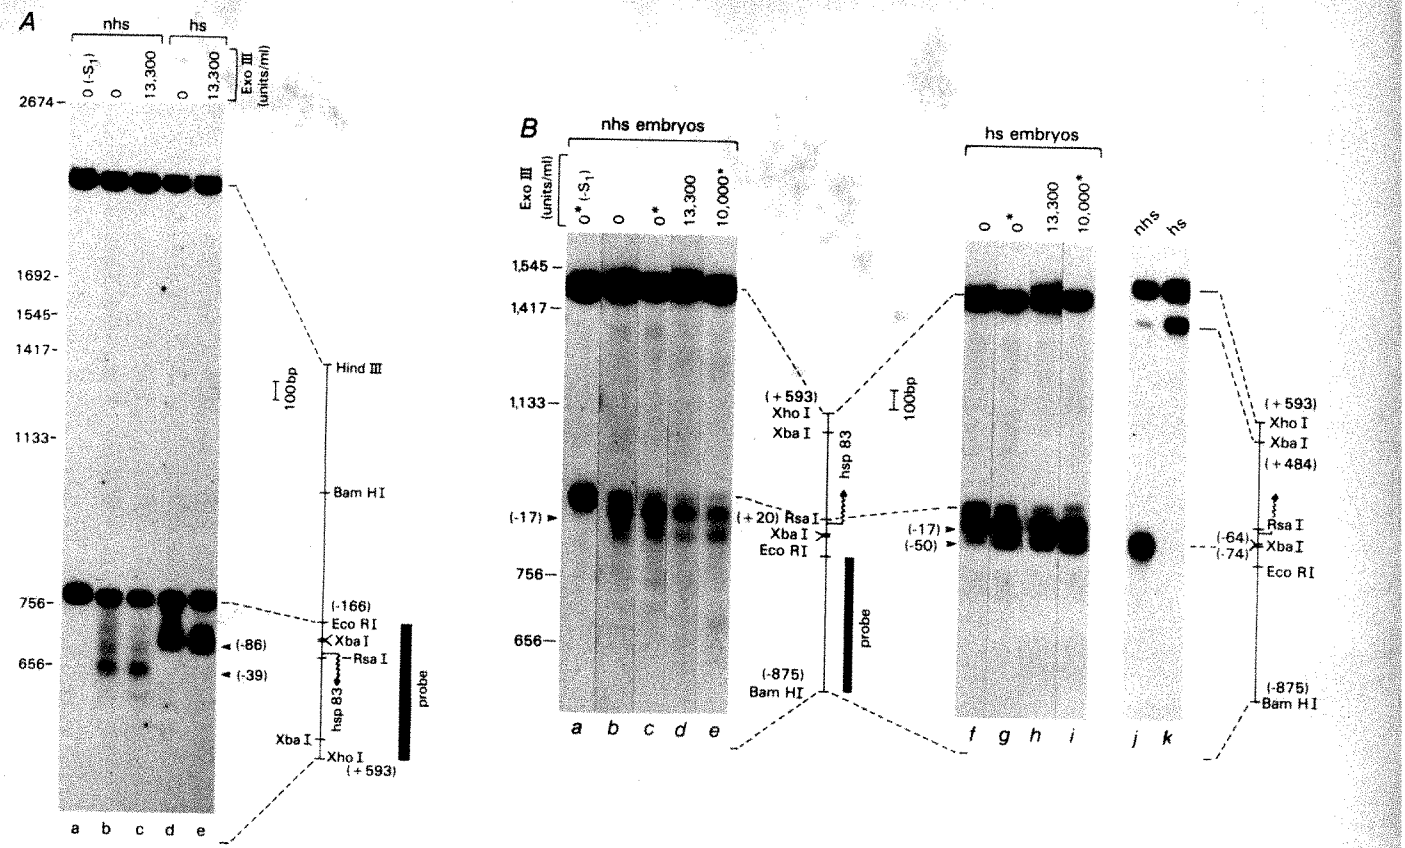

Fig. 5 ***A***, Exo III digestion from the *Eco*RI cut at position −166 in normal and induced hsp83 gene chromatin. A partial restriction map of the hsp83 gene region is shown[28,30]. Isolated nuclei from normal (lanes *a-c*) and heat-shocked (lanes *d, e*) 2–8 h-old embryos were digested with *Eco*RI at 4,200 U ml^{-1} plus Exo III as indicated for 7 min at 30 °C. The purified DNA was trimmed with S_1 nuclease (except in lane *a*), repurified, restricted with *Xho*I + *Hind*III, electrophoresed on a 40-cm long, 1.4% 50 mM Tris-borate EDTA *p*H 8.3 (TBE) gel, blotted and hybridized with the cloned probe (solid bar) as described in Fig. 2*B* legend. Arrowheads indicate the stop positions of Exo III and the endogenous exonuclease. ***B***, Exo III digestion from the *Rsa*I cut at position +20 in normal and induced hsp83 gene chromatin. Isolated nuclei from normal (lanes *a–e*) and heat-shocked (lanes *f–i*) 2–8-h-old embryos were digested with 1,500 U ml^{-1} *Rsa*I plus Exo III as indicated, for 15 min at 35 °C (lanes *a, c, e, g, i*)* or with 1,700 U ml^{-1} *Rsa*I plus Exo III as indicated for 7 min at 30 °C (lanes *b, d, f, h*). The purified DNA was trimmed with S_1 nuclease (except in lane *a*), repurified, restricted with *Bam*HI + *Xho*I, electrophoresed on a 1.4% 50 mM TBE gel, blotted and hybridized with the cloned probe (solid bar) as described in Fig. 2*B* legend. Lanes *j, k*, *Xba*I cleavage of hsp 83 chromatin. Isolated nuclei from normal (lane *j*) and heat-shocked (lane *k*) 2–8-hr-old embryos were digested with 1,400 U ml^{-1} *Xba*I at 35 °C for 15 min. The purified DNA was restricted with *Bam*HI + *Xho*I, electrophoresed beside the above samples and processed similarly.

digestion in the nucleosome core particle[38–40], but is similar in size to the fragments resistant to digestion when prokaryotic activator and repressor proteins are bound to DNA[41]. We suggest that the resistance is due to at least two nonhistone proteins which bind specifically to duplex DNA in the TATA box region (TATA-binding protein(s), TAB), and the upstream heat-shock control region (heat-shock activator protein(s), HAP) respectively (Fig. 6*b*). (Since Exo III is also unable to digest single-stranded DNA, the resistance to cleavage could conceivably occur by a melting of the sequences, but this is improbable because the sites are resistant to DNase I cleavage too.)

We conjecture that the binding of TAB establishes the transcriptional potential of heat-shock genes in (post-blastoderm) embryos. This potential is realized during heat-shock activation by the additional binding of HAP. The fact that site II only appears in the active gene argues that HAP is a positive activator of transcription; a repressor should have had the reverse effect. Others have also argued for positive regulation in the sense that deletions in the upstream element reduce transcription during heat shock rather than cause constitutive expression[33,34]. Only after TAB and HAP are bound might transcription be initiated by RNA polymerase II. The significance of protein-protein contacts in the binding of polymerase II to eukaryotic promoters has been argued[42].

The displacement of a nucleosome from the TATA box region by TAB, combined with the perturbation of higher order contacts between neighbouring nucleosomes in the native chromatin fibre, could be sufficient to create nuclease hypersensitivity over the adjacent sequences, its relative intensity and spread being influenced by the local sequence order. Such a displacement could occur during transient reassembly of chromatin during DNA replication.

Is the TATA box sequence in all genes which possess it bound to TAB in chromatin? This seems unlikely in view of other work on developmentally regulated genes which suggest a nucleosomal arrangement over promoter sequences in all but the expressing tissue. Although no obvious additional homologies have been generally found within 10 bp around the TATA box[37], Holmgren *et al.*[29] have pointed out an eight base homology (A/G)C(C/A)GGCGC immediately following the TATA box in the heat-shock gene family, which, curiously enough, is also present at the same locations in the *Drosophila* histone H4 and alcohol dehydrogenase genes (noted in ref. 33) but not in other *Drosophila* genes. All TATA binding functions could be governed by a small group of TAB proteins, each of which is able to bind to a 'TATA(+)' consensus sequence common to one or more gene families. Davidson *et al.*[43] have recently reported a Hela cell factor which is necessary for *in vitro* transcription from conalbumin and adenovirus late promoters, which binds to the TATA box region in the absence of polymerase II and forms a stable pre-initiation complex. It is interesting to speculate that TAB may fall into this class of transcription factors.

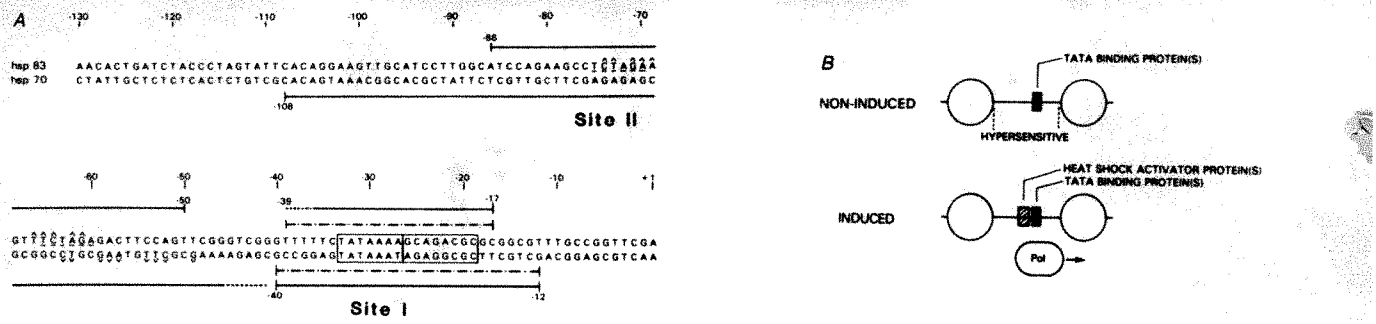

Fig. 6 ***A***, Exonuclease resistant sites aligned over nucleotide sequences upstream of the 5′ ends of the hsp83 and hsp70 genes. The sequences are copied from Holmgren *et al.*[29]. The initiation site of transcription of both genes is shown as +1. Boxed sequences indicate homologies shared between these and other *Drosophila* heat-shock genes[29]. Capped nucleotides indicate the consensus sequence that is required for heat induction[35]. Underlined nucleotides indicate the two *Xba*I sites upstream of the hsp83 gene. Lines above and below the sequences are resistant nucleotides in hsp83 and hsp70 gene chromatin respectively. —·—·—, Resistant nucleotides in the noninduced genes; ——, resistant nucleotides in the induced genes. Boundaries of the resistant regions are precise to five base pairs. Undeterminable boundaries are indicated by dots following the solid lines. ***B***, A model for the heat-shock promoter region in chromatin during normal and induced states. Circles represent nucleosomes; their positions have not been determined. Pol refers to RNA polymerase II.

Our simple model does not attempt to account for the more subtle nuances of heat-shock gene expression, such as the developmental control which is superimposed on the hsp83, hsp28 and hsp26 genes in *Drosophila* ovarian nurse cells[44]. We hope it will be useful as a framework for comparison with the rest of the heat-shock gene family and for defining the minimal components essential for heat-shock gene expression. Aspects of the model are generally applicable to the regulation of other eukaryotic genes.

This work has focused on the localization of barriers against convergent Exo III nibbling from cuts on either side of a nuclease hypersensitive site. Divergent cleavage, presumably into adjacent nucleosomal DNA, might reveal the positions of neighbouring nucleosome core particles. We have not extended our analysis into this area, except in one example averaged over the five heat-shock genes, and this result appears to argue in favour of a statistical[45] location of these nucleosomes (Fig. 2*B*). A more detailed analysis is required to address this question properly.

The Exo III protection technique could be used for mapping other protein-binding sites in chromatin. Clean results are obtained especially when a single-cut restriction enzyme is used to make the initial cleavage in the hypersensitive region. We have found empirically that mild conditions for restriction and Exo III cleavage (30 °C, 10–15 min) using several thousand units per ml of restriction enzyme can result in cleavage of more than 50% of the molecules at a particular hypersensitive site, of which roughly 50–100%, depending on the site, can be digested further by the endogenous exonuclease or Exo III. Thus, the resistant sites occur in a significant fraction of the overall population. For ultimate precision in site mapping, the exonuclease resistant fragments can be separated on sequencing gels (without prior S_1 trimming), and the appropriate strand labelled with a single-stranded probe after blotting to nylon membranes according to a new protocol[46].

I thank R. Morimoto, R. Holmgren, R. Blackman and M. Meselson for gifts of cloned heat-shock genes, and for communicating unpublished sequences, and J. Lis for the latter. I thank my colleagues for helpful suggestions, M. Singer for a critical review of the manuscript, T. Paisley for technical assistance and B. Wood for maintaining our *Drosophila* colony.

Two types of binary radio pulsars with different evolutionary histories

E. P. J. van den Heuvel

Astronomical Institute, University of Amsterdam, Roetersstraat 15, 1018 WB Amsterdam, The Netherlands

R. E. Taam

Department of Physics and Astronomy, Northwestern University, Evanston, Illinois 60201, USA

The four known binary radio pulsars (Table 1) seem to fall into two different categories. Two of them, PSR0655+64 and PSR1913+16, have short orbital periods (<25 h)[1,2] and high mass functions, indicating companion masses >0.8 $M_\odot$ (respectively, about 1 $M_\odot$ and 1.4 $M_\odot$ (ref. 2)). The other two, PSR0820+02 and PSR1953+29, have long orbital periods (≳ 120 days), nearly circular orbits and low almost identical mass functions of ~3×10^{-3} $M_\odot$, suggesting companion masses of ~0.2–0.4 $M_\odot$ (refs 3–5). We point out here that these two classes of systems are expected to be formed by the later evolution of binaries consisting of a neutron star and a normal companion star, in which the companion was (considerably) more massive than the neutron star, or less massive than the neutron star, respectively. Mass transfer from an evolved companion that is more massive than the neutron star (more precisely, mass ratio ≳0.85 (refs 6, 7)) tends to be unstable and to lead to runaway mass transfer and spiral-in resulting in a very short orbital period, whereas mass transfer from an evolved companion that is less massive than the neutron star is stable and leads to expansion of the orbit[6,7]. Furthermore, we point out that in the systems with a less massive companion, the neutron star most probably was formed by the accretion-induced collapse of a white dwarf. Such a model explains in a natural way why PSR1953+29 has a millisecond rotation period and why PSR0820+02 has not.

When the companion has a mass several times that of the neutron star (≳3–4 $M_\odot$, see below) and the system is relatively wide (orbital period ≳ a few weeks) so that at the onset of the mass transfer the companion has a deep convective envelope, runaway mass transfer is unavoidable. This is because (1) mass transfer from the more massive to the less massive star leads to shrinkage of the Roche lobe of the more massive star, while (2) a convective envelope tends to expand when the star loses mass[8]. This will, on a time scale of ~10^3 yr, lead to the formation of an extended convective common envelope in which the neutron star and the evolved core of the companion will spiral towards each other as a consequence of the large frictional drag[9–12]. The duration of this spiral-in process, in which finally the envelope is lost, is expected to be short, ~10^3–10^5 yr (refs 11–13).

The final result is expected to be a system consisting of the neutron star and the evolved core of the companion with an orbital period ranging from ~1 h to a few days (in analogy to the case of cataclysmic variables which are products of a similar type of spiral-in evolution[9,12]).

In order to have deep spiral-in, the two components should differ sufficiently in mass, preferably by more than a factor of two, because otherwise soon after the onset of the mass transfer the mass ratio will be reversed which would lead to subsequent spiral-out. (For systems with mass ratios in the range 0.85–2 the outcome of the evolution is more complex and, for the sake of argument, will not be considered here.)

Figure 1 depicts as an example the anticipated evolution of a binary initially consisting of a $M = 5M_\odot$ star and a neutron star, with an orbital period of ≳80 days. The $5M_\odot$ star overflows its Roche lobe when it has exhausted helium in its core (that is, when it climbs up along the asymptotic giant branch, AGB). At helium exhaustion it has a 0.95 $M_\odot$ degenerate CO core[14] surrounded by He and H-burning shells. During its ascent of the AGB this core mass increases to 1.39 $M_\odot$. We assume that the star engulfs its companion when $M_{core} \simeq 1.0\ M_\odot$, implying a binary period of about 100 days (see Table 2). The system after spiral-in will consist of a 1.0 $M_\odot$ CO white dwarf and a neutron star with a narrow and a circular orbit, that is, closely resembling the PSR0655+64 system (see Table 1). The type of binary evolution considered here is the so-called case C [6,7]. (In shorter-period systems—case B—the evolution will be somewhat more complex and may lead to several stages of mass transfer[15,16]; the outcome will, however, in most cases be roughly similar[15].) Table 2 lists the maximum and minimum orbital periods for case C evolution for companion masses in the range 3–7 $M_\odot$, derived from Paczynski's[14] evolutionary tracks. The corresponding CO core masses are also listed.

Table 2 shows that an evolution similar to the one depicted in Fig. 1 is expected in all wide (case C) neutron star binaries in which the mass of the companion is in the range ~5 to ~8 $M_\odot$, as on the AGB all such stars develop degenerate CO cores with a mass in the range 0.95–1.39 $M_\odot$ (refs 14, 17, 18). For companion masses of 3–5 $M_\odot$, the same holds if the binary periods are ≳80 days, such that after helium exhaustion the core can still grow to ≳0.90 $M_\odot$ before the star overflows its critical lobe. Companions more massive than ~8–10 $M_\odot$ will develop evolved cores too massive to terminate as white dwarfs[15,19]. Following the spiral-in and subsequent nuclear evolution such a core is expected to collapse to a neutron star. The mass ejection in this second supernova in the system may induce a considerable orbital eccentricity or may even disrupt the system[20,21]. PSR1913+16 is expected to have been formed in this way[21,22] (in the case of disruption, two runaway neutron stars will be formed, one young and one old).

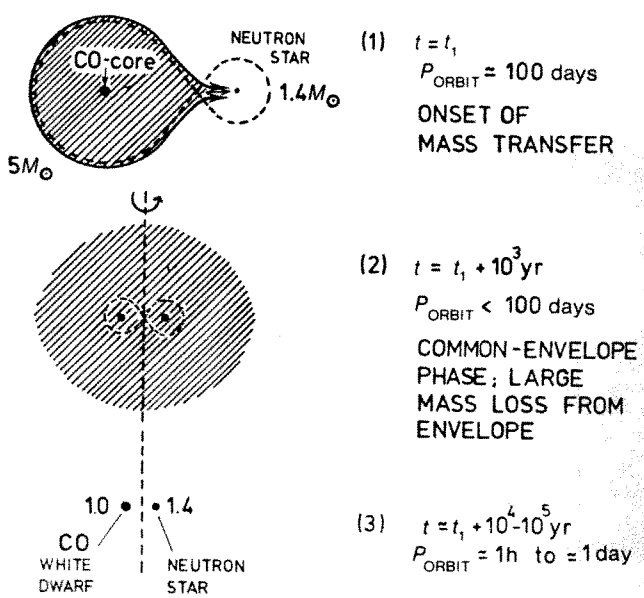

Fig. 1 Anticipated evolution of a relatively wide binary consisting of a 5 $M_\odot$ star with a neutron star companion. At the onset of the mass transfer the 5 $M_\odot$ star is a giant with a 1 $M_\odot$ degenerate CO core and a gradually expanding envelope (1). Rapidly, a common convective envelope forms (2) in which the CO-core and the neutron star spiral-in. During this spiral-in the envelope is ejected due to frictional heating and a very close system remains (3) consisting of a neutron star and a massive CO-white dwarf in a circular orbit. All wide (case C) neutron star binaries with companions in the range 3 $M_\odot$ to 8–10 $M_\odot$ are expected to evolve in this way. For companions more massive than 8–10 $M_\odot$ the evolved core after spiral-in collapses to a neutron star, and a close neutron star binary with an eccentric orbit (or two runaway pulsars) will be formed[20–22].

At the onset of the spiral-in the neutron star will often be older than 10^7 yr (companion stars of 5–15 $M_\odot$ need some (1–5) × 10^7 yr to leave the main sequence) such that its surface magnetic field strength may have decayed by several orders of magnitude. (The space distribution of radio pulsars with known proper motions indicates that the dipole strength of the surface magnetic field of a neutron star decays on a time scale of (2–5) × 10^6 yr (refs 23–25).) With a canonical magnetic dipole strength at birth of $\sim 10^{12-13}$ G (refs 23–25), the dipole strength at the onset of spiral-in may thus be $\sim 10^{10-11}$ G, as observed in PSR0655+64 and PSR1913+16 (see Table 1). During the spiral-in the accretion onto the neutron star will take place near the Eddington-limited rate $\dot{M}_{\rm Edd}$, implying that its rotation will be spun-up to a minimum period that depends practically only on the surface dipole strength B_9 (in units of 10^9 G) as[21,26,27]

$$P = (2.7\ \text{ms})\ B_9^{6/7}\ R_6^{15/7} \left\{\frac{M}{1.4\ M_\odot}\right\}^{-5/7} \left\{\frac{\dot{M}_{\rm Edd}}{\dot{M}}\right\}^{3/7} \qquad (1)$$

where R_6 is the neutron star radius in units of 10^6 cm and M is its mass. After the loss of the common envelope these neutron stars will become observable as radio pulsars with a relatively low surface dipole magnetic field strength[21,22,24]. For the observed B_s values of PSR0655+64 and PSR1913+16 (Table 1), and $R_6 = 1$, $M = 1.4\ M_\odot$, equation (1) yields $P = 0.17$ and 0.04 s, respectively, in reasonable agreement with their observed pulse periods (allowing for some spin-down since their formation[21,24]).

The absence of radio pulses from the second (younger) neutron star in the PSR1913+16 system may be due either to beaming effects, or to the relatively short spin-down time scale of a newborn strong-magnetic field neutron star (if the second supernova in the system took place a few million years ago, the new neutron star may already have reached the turn-off period of a few seconds whereas the 'recycled' old one, due to its weaker surface dipole field, will remain observable as a pulsar for a much longer time[21,22,27,28]). The best known progenitor candidates for the above described type of evolution seem to be the B-emission X-ray binaries, which have orbital periods ranging from 15 days to several years[29,30], and companion masses ranging from $\sim 7\ M_\odot$ (spectral type B3Ve) to $\sim 20\ M_\odot$ (spectral type O9Ve). The companion of PSR0655+64 should have had a mass below the limit for exploding as a supernova, $\leq$8–10 $M_\odot$ (in case C; in case B: $\leq$10–12 $M_\odot$) whereas that of PSR1913+16 had a mass above this limit (see ref. 21 for details).

We now turn to the alternative case in which the system started out with a companion star less massive than the neutron star. When in this system (mass ratio ≤ 0.85) the companion begins to overflow its Roche lobe, the ensuing mass transfer will be self-stabilizing as it leads to expansion of the orbit. Webbink *et al.*[31] and Taam[32] have shown that in this way, starting with companions with $M \leq 1.2\ M_\odot$ and orbital periods upwards from about 1 day, one obtains a long-lasting ($\sim 10^6$–10^8 yr) stage of relatively high mass transfer ($\dot{M} \geq 10^{-8}\ M_\odot\ \text{yr}^{-1}$).

During this phase the companion ascends the giant branch and has a degenerate helium core with a mass in the range 0.2–0.45 $M_\odot$, and generates energy by burning hydrogen in a shell around this core. The mass transfer, and the associated expansion of the orbit, are driven by the gradual growth of the core mass. The duration of the mass transfer phase depends mainly on the initial mass of the companion and the initial orbital period. In the end, only the degenerate helium core of the companion is left behind, as a helium white dwarf, and the final orbit will always be wide, as the mass and orbital angular momentum of the system are, in first approximation, expected to be conserved.

Savonije[33], Paczynski[34] and Joss and Rappaport[35] have, independently, pointed out that the final systems resulting from this evolution show a striking resemblance to that of the 6-ms binary radio pulsar PSR1953+29, as (1) the final companion mass will be low ($\sim 0.3\ M_\odot$) and (2) the orbit will be (almost) circular as a consequence of the long-lasting preceding mass transfer stage. (When the companion is a red giant which is filling its Roche lobe, tidal dissipation in its convective envelope will be very efficient[36,37].) Rappaport and Joss[35] showed that for an initial mass of the companion of 1 $M_\odot$, the most likely initial orbital period of PSR1953+29 was around 10 days and that of PSR0820+02 about 1 yr. The duration of the mass-transfer phase in these systems was (3.5–7.7) × 10^7 yr and 4 × 10^6 yr, respectively (similar results are obtained for a companion mass of 1.2 $M_\odot$, as can be easily verified).

The above outlined evolutionary model for these wide systems thus seems to explain their observed orbital characteristics, including their mass functions; but this model at the same time implies that the systems must be very old (at least several times 10^9 yr) as the companion stars should have started out with masses $\leq 1.2\ M_\odot$ and had already completed their main-sequence evolution before the onset of the mass transfer. Because surface dipole components of magnetic fields of neutron stars seem to decay on a time scale $\leq 10^7$ yr one would, therefore, not expect any detectable surface dipole fields to be left in them.

However, PSR0820+02 and PSR1953+29 still have a surface dipole magnetic field strength of 3 × 10^{11} G and $> 10^9$ G, respectively (Table 1). The same problem exists in the GX 1+4 system which is an 120 s X-ray pulsar, and must be a very wide system as the companion star is an M6IIIe red giant[38]. Such a system seems an excellent progenitor candidate for a system like PSR0820+02 (ref. 39). From its spin-up rate in combination with its X-ray luminosity of $\sim 10^{38}$ erg s^{-1} (ref. 38) one derives a lower limit to its magnetic field strength of $\sim 3 \times 10^{11}$ G (ref. 26), which is similar to that of PSR0820+02. Because an M6IIIe giant cannot be more massive than $\sim 3\ M_\odot$ (ref. 14), the age of this system is at least $\geq 2 \times 10^8$ yr (the main-sequence lifetime of a 3 $M_\odot$ star). Moreover, the position close to the galactic centre and at high z suggests an old-disk population old age of (5–10) × 10^{10} yr.

The only consistent way in which one may explain why the neutron stars in these old (wide) systems still can have such fairly strong surface magnetic fields seems to be if they were formed only recently—during the mass-transfer stage itself, by the accretion-induced collapse of a (relatively massive) white dwarf. (It seems reasonable to assume that, regardless of the formation mechanism, all neutron stars are formed with a canonical surface dipole magnetic field strength of 10^{12-13} G, due to dynamo action during the collapse process[25].) Because in the case of PSR1953+29 the mass transfer stage lasted (3.5–7.7) × 10^7 yr and for PSR0820+02 it lasted only $\sim 4 \times 10^6$ yr, the time elapsed since the collapse in these systems may be relatively short: a few times 10^7 yr in the case of PSR1953+29 and $< 10^7$ yr in the case of PSR0820+02, respectively. Hence, one would not expect their surface magnetic fields to have decayed by more

Table 1 Orbital and pulse properties of the four binary radio pulsars together with estimates of their surface magnetic field strengths and the masses of their companions

Name	$P_{\rm orb}$ (day)	e	Mass function ($M_\odot$)	Most likely companion mass ($M_\odot$)	$P_{\rm pulse}$ (s)	B_s (G)	Ref.
PSR1913+16	0.32	0.617	0.1322	1.40 ± 0.05	0.059	2×10^{10}	1
PSR0655+64	1.03	0.000	0.0712	1.00 ± 0.30	0.196	8.6×10^{10}	2
PSR0820+02	1,232	0.012	0.00301	0.2 – 0.4	0.865	3.3×10^{11}	4
PSR1953+29	~120	<0.05	0.00272	0.2 – 0.4	0.006	$\sim 2 \times 10^9$ (predicted)	5, 47

Table 2 Minimum and maximum orbital periods for neutron star binaries in which the companion overflows its critical lobe after it has exhausted helium in its core (case C evolution)

Companion mass	P_{min} (day)	M_{core} (He exhaustion) ($M_\odot$)	P_{max} (yr)	M_{core} (max) ($M_\odot$)
$3M_\odot$	32	0.51	5.5 (19)	1.39
$5M_\odot$	76	0.95	4.5 (13)	1.39
$7M_\odot$	173	1.02	3.6 (10)	1.39

A neutron star mass of 1.40 $M_\odot$ was assumed and the corresponding masses M_{core} of the degenerate CO-core of the companion are indicated (Paczynski's[14] evolutionary tracks were used). The first value of P_{max} corresponds to the moment at which the orbital separation equals the radius of the companion; the value within parentheses corresponds to the moment at which the companion fills its Roche lobe.

than a factor of 10^3 and 10^1, respectively. That PSR0820+02 indeed still has the strongest magnetic field of the two is therefore in excellent agreement with the prediction of this accretion-induced collapse model.

In addition, the conditions for achieving accretion-induced collapse are expected to be favourable just in systems with a low-mass ($\leq 1.2\ M_\odot$) giant component for the following reasons. To reach collapse the white dwarf (consisting of CO or O–Ne–Mg) should be able to grow substantially by accretion—as the *a priori* probability that it was born with a mass close to the Chandrasekhar limit will be very low. Just at the accretion rates produced by low-mass giant companions (in the range $10^{-8}\ M_\odot\ yr^{-1}$ to $2\times10^{-7}\ M_\odot\ yr^{-1}$) a considerable growth of the white dwarf is indeed possible as the accreted hydrogen burns in shell flashes that are too weak to cause mass ejection[40–42]. At lower accretion rates, $<10^{-8}\ M_\odot\ yr^{-1}$, hydrogen burns with very strong nova-like flashes in which part (and possibly all) of the accreted matter is ejected such that a substantial growth of the white dwarf is unlikely. In addition, at the age of these systems ($\geq 10^9$ yr) the oxygen in a carbon–oxygen white dwarf may have separated from the carbon and have settled in the core[43], creating a situation favourable for the occurrence of accretion-induced collapse[44].

Because, at any time during the accretion phase the envelope mass of the white dwarf is small (more than a few hundredths of a solar mass of hydrogen would not fit inside its Roche lobe) and because the mass loss of the white dwarf during the collapse need not exceed the equivalent of the binding energy of the neutron star ($\sim 0.1\ M_\odot$), the orbital eccentricity induced by the mass loss in the collapse need not exceed 0.05 (ref. 20) and the orbit may be subsequently circularized by the continued mass transfer from the companion and by tidal forces[39,45].

The above described model is entirely consistent with the very short (6 ms) pulse period of PSR1953+29, because in the PSR1953+29 system the collapse can have occurred several times 10^7 yr before the end of the mass-transfer phase. Consequently, the surface dipole field had time to decay to $\leq 2\times10^9$ G and according to equation (1), spin-up to $\sim$5 ms was possible. On the other hand, in view of the much shorter mass-transfer time scale in the PSR0820+02 system, such a field decay and spin-up to a short period were not possible here.

Thus we conclude, on the basis of the above arguments, that the existence of the two binary radio pulsars with wide circular orbits and low-mass functions, provides the first very strong evidence that neutron stars can be formed in an old stellar population by the accretion-induced collapse of a white dwarf in a relatively wide binary (Whelan–Iben model[46]).

We thank H. Henrichs, G. J. Savonije, J. van Paradijs, V. Radhakrishnan, R. Blandford and M. Goss for stimulating comments and discussions, V. Boriakoff for providing information on PSR1953+29 in advance of publication, and V. Trimble for suggestions. This work started during the CECAM workshop on "Late Stages of Close Binary Evolution" in Meudon (France), July/August 1982.

Cosmic dust collection by the capture cell technique on the Space Shuttle

J. A. M. McDonnell, W. C. Carey & D. G. Dixon

Space Sciences Laboratory, University of Kent at Canterbury, Kent CT2 7NT, UK

The capture cell technique is a new approach to the study of extraterrestrial material: although complementary to stratospheric collection techniques[1], it avoids selection effects introduced by the deceleration of dust in the Earth's atmosphere. The method, to be used extensively in cosmic dust retrieval experiments on the forthcoming NASA Long Duration Exposure Facility, now yields results from its first application in the microabrasion foil experiment (MFE) which was flown as part of the scientific payload on the STS-3 Space Shuttle mission. Post-flight analysis yielded four hypervelocity impact perforation events during 8 days of exposure to space, and confirmed the capture cell technique as a viable low-cost method for the assessment of the near-Earth particulate environment. The effectiveness of a meteoroid bumper[2] in dissipating incident particle energy is strikingly demonstrated; markedly different and yet unexplained perforation morphologies are observed and a revision of the current near-Earth microparticle influx model[3] is suggested.

MFE was exposed over 8 days in a circular Earth orbit of 241 km altitude and 38° inclination, recording a total of one large (23 μm diameter) and three near-marginal perforations

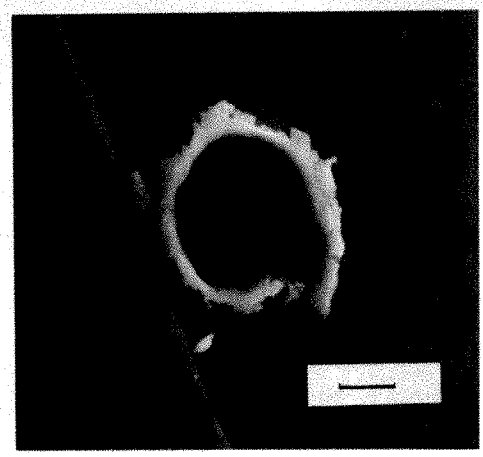

Fig. 1 Scanning electron micrograph of the impact side of the largest aluminium foil perforation (23 μm diameter). Evidence of target melting, raised crater lips and circular symmetry, and especially close correspondence with the exit side (see Fig. 2*a*) indicates that it was caused by a particle considerably smaller than 23 μm; at an assumed velocity of 15 km s^{-1}, a particle diameter of 10 μm is required based on simulation and experiment. Scale bar, 10 μm.

(5.1, 6.5 and 7.5 μm in diameter, respectively). The experiment comprises a double layer foil structure[4]; the top layer of 5-μm aluminium foil is held ~1 mm above a Kapton sheet by a gold-coated brass spacer grid in a 1-m^2 rectangular array with an effective detection area of 0.4 m^2. An actual exposure time to space, computed from the shuttle manoeuvring records provides an area–time product of 1.52×10^5 m^2 s (corrected for Earth shielding). Penetration experiments[5] on identical aluminium foils with iron microparticles show that dust particles with masses $>10^{-12}$ g will marginally penetrate the 5-μm aluminium foil. Particles of lower density would have a larger mass threshold, scaled, for example[6], according to a dependence on (projectile density)$^{1/2}$. For marginal perforations, expansion velocities behind the foil are reduced to some small fraction of the initial impact speed, but for those typical of the larger perforation, the particle totally vaporizes[7] and expands into the capture cell with little reduction of velocity. Impact debris and vapour strike the Kapton sheet over an area much greater than the area of the first perforation. Both particulate matter and vapour from the impact will adhere to the Kapton, but lighter volatiles may condense on both inner surfaces of the capture cell.

Impact perforations in the returned foils were located in the laboratory by a visual inspection system on a light table: preflight records of defects in the foils were compared with identical post-flight inspection and locations of candidates for possible hypervelocity perforations then fully examined in a scanning electron microscope. Tears and defect-associated perforations were rejected. A sensitivity of 3 μm diameter perforation is superior to the lower limit of perforation from hypervelocity impact[4], thus affording confidence that only four perforations were accumulated.

Figure 1 shows the 'entrance' side of the largest perforation and Fig. 2 the rear (exit) side of all four microparticle perforations. The exit sides show most striking morphological characteristics and also differences between the four events. The entrance morphology of all perforations is very similar, having circular lips extending away from the foil surface as seen in laboratory simulations[8].

The first and largest perforation detected (Figs 1, 2*a*) possesses very distinctive hypervelocity impact features, as would be expected from a comparatively large cosmic dust particle. Lips around the hole on both the front and rear foil surfaces are almost identical and demonstrate clear evidence of expansion after the passage of the particle, a feature shown in computer simulations[7] of impact at 68 km s^{-1}. Radial symmetry is observed and absence of deformation away from the crater lips gives evidence of a particle considerably smaller than 23 μm diameter. On the rear side of the aluminium foil, near the crater, an area of debris is seen, approximately circular with a diameter of 100 μm and centred on the perforation. It consists of submicrometre globular particles and micrometre-sized irregular iron-rich particles and may arise from the condensation of impact vapour. It could also contain 'splash-back' from the Kapton as well as condensed foil material. With this perforation, an extensive impact debris zone was found on the underlying Kapton sheet (Fig. 3), of diameter 200 μm but penetrating only to a depth of 1 μm—a marked demonstration of a meteor bumper dissipating the energy of an incident particle and of a high impact velocity. This was offset by some 500 μm from the top crater; from the concentric distribution relative to the perforation rather than the debris, we conclude that it is possible for a fraction of the expanding projectile and target to condense on the rear side of the first foil, but certainly most material impacts the Kapton first.

Returning briefly to the morphology of the three marginal perforations (Fig. 2*b*, *d*), distinctive petalling of the perforation lips and often a separation into layers is observed. This is not seen in laboratory simulations (performed with a 2-MV van der Graaff dust accelerator) at this scale. The origin of the feature seen in Fig. 2*c*, thought perhaps to be an exploded liner of a compressed micrometeoroid, is also unknown, but from energy-dispersive X-ray spectroscopy (EDS) analyses no material other

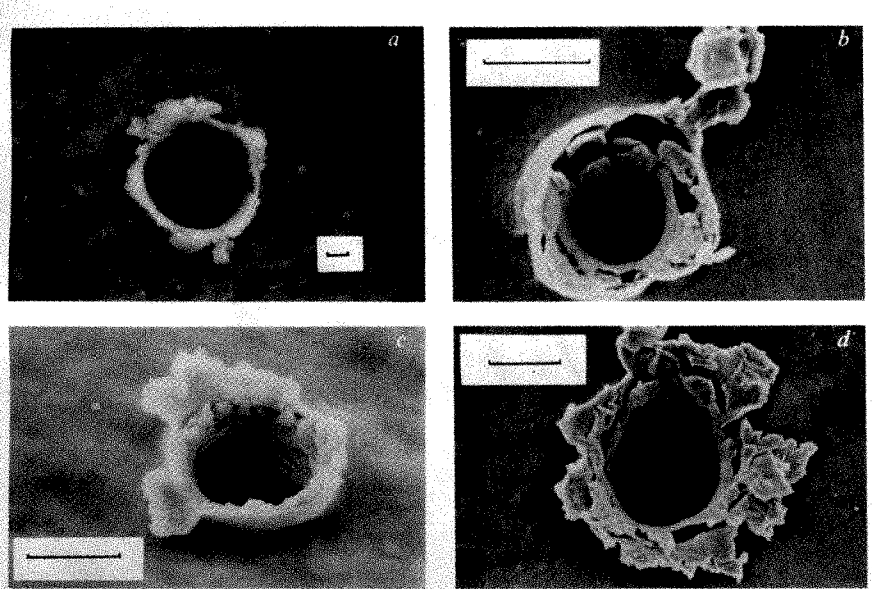

Fig. 2 Exit side of the four perforations showing: *a*, the largest perforation (23 μm); *b–d*, three near-marginal perforations of diameter 5.1, 6.5 and 7.5 μm, respectively. Although strikingly different in morphology and unmatched in microscale impact studies, *b–d* retain evidence of a melted surface of the primary crater 'liner' which is peeled open at the terminal stage of perforation. *c* could show evidence of particle retention comprising a liner of some 1 μm thickness. Scale bars, 5 μm.

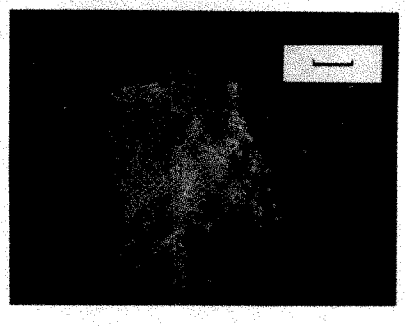

Fig. 3 Second surface debris from the largest crater collected on the Kapton substrate. Damage extends to an area of 200 μm in diameter, but is restricted to 1 μm in depth. Trails of droplets (identified as aluminium from the target) are seen forming both radial streamers and in a hollow conical distribution near the edges of the debris. Scale bar, 50 μm.

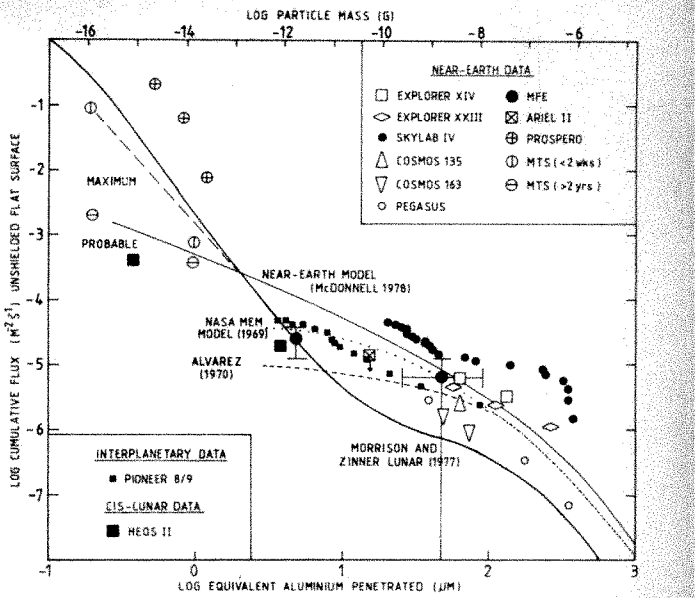

Fig. 4 Relevant flux measurements in the vicinity of 1 AU heliocentric distance[3] corrected for Earth shadowing and reduced to a flat surface exposure geometry. The MFE yields a flux of $\Phi = 2.6\times10^{-5}$ m^{-2} s^{-1} (flat surface sensor of π sr effective exposure angle corrected for Earth shielding) for a perforation thickness of 5 μm aluminium, or $m = 1.8\times10^{-12}$ g particle mass; it differs significantly from previous models and supports a more pronounced flattening of the size distribution at masses 10^{-12} g. If the lunar data and the near-Earth Prospero measurements are reliable indicators of the incident flux in Earth orbit, the trend would (shown above on a cumulative plot) support the existence of a bimodal particle distribution[12]; the significance of secondary cratering in lunar data at low masses must be addressed.

than aluminium has been detected; it may represent a mixed projectile and target with sufficiently different thermal properties to differentiate on cooling. Initial EDS examinations have, however, revealed silicon surrounding these structures. Full results of these analyses is continuing and will be reported elsewhere, as will a more detailed morphological discussion of the mechanics of penetration. Examining briefly the flux rate measured during the mission, however, we find the data offers significant insight into what could be a different understanding of some near-Earth microparticle flux data.

Figure 4 transposes the penetration data to a mass scale based on penetration experiments[5] and significant data from deep space and lunar measurements at 1 AU heliocentric distance. Two factors concerning exposure geometries must be clarified before the fluxes may be validly compared, namely sensor angles and flux isotropies. The MFE experiment offers unshielded 2π sr geometry and may be compared with data such as those of the lunar surface without geometric corrections. This configuration has generally been referred to as an area–time product in m^{2}s 2π sr, and yet considering an element of solid angle $d\Omega$ of a sensor A m^2 exposed at an angle θ of a unit sphere, we note that the product of the effective area (A_{eff}) and solid angle ($d\Omega$) is $A_{eff}d\Omega = A\cos\theta\, 2\pi\sin\theta\, d\theta$. Hence the total area–time product is

$$\int_0^{\pi/2} A_{eff}\, d\Omega = 2\pi A \int_0^{\pi/2} \cos\theta \sin\theta\, d\theta = \pi A \quad \text{m}^2\,\text{sr}$$

We should thus relate an unshielded flat sensor to a true exposure solid angle of π sr. We therefore now scale the directional measurements from sensors of solid angle Ω_p by the ratio π/Ω_p and note that the lunar data need not be changed numerically, but do refer to π sr exposure. The Pioneer 8 and 9 deep space interplanetary data were previously incorrectly scaled[3] by the ratio $2\pi/\Omega$. Such corrections have the effect of reducing measurements of the interplanetary flux by a factor of 2 (Fig. 4). For anisotropic fluxes, we note that at masses of $\sim10^{-11}$ g or greater, the data show[3] a strong predominance towards an Earth apex flux from the forward orbital motion of the near-circular orbit of the Earth into slower particles near their aphelion[9]. To such a flux, a rotating sensor of area A offers an effective area of

$$\frac{2}{\pi}\int_0^{\pi/2} A\cos\theta\, d\theta = \frac{2A}{\pi}$$

over angles $\pm\pi/2$ radians to the apex direction and 0 for $\pm\pi/2$ to $\pm\pi$ radians (shielded), yielding an average of A/πm^2. Hence, to estimate the average flux intercepted by sensor rotating in an apex dominant 'stream' we must multiply such measured apex flux values by $1/\pi$. Gravitational enhancement[10] in comparing lunar and near-Earth data must be considered, but this is not included in Fig. 4.

The relationship between foil thickness penetrated and particle mass/crater pit diameter is found[5] by assuming a particle density of 3 g cm^{-3} and a velocity of 20 km s^{-1}, which results in a 1-μm crater pit diameter being equivalent to 2.33 μm of aluminium. The MFE data in Fig. 4 are plotted at a measured cumulative penetration flux for $t = 5$ μm foil thickness for the four perforations; also estimated is the foil thickness which the particle forming the largest perforation would have perforated, namely $t = 48$ μm. This perforation is estimated by impact data[5] to have been caused by a particle of diameter 10 μm at an assumed velocity of 15 km s^{-1}. A recent near-Earth flux model[3], which interpolated through the region of sparse penetration data, is now seen to have been overestimated at masses in the region of 10^{-12} g, probably by one magnitude and at least by a factor of five. Despite the small number of hypervelocity events recorded by MFE, we stress that penetration is a highly reliable sensing technique. An exaggeration of the flux value may occur if, for example, foil defects are falsely attributed to extraterrestrial impacts, but the crater morphology precludes this possibility; scanning by two observers has established the efficacy of the MFE detection with regard to the possibility of missing perforations. Even the statistical uncertainties of the flux measure based on four events, yielding an accuracy of ±50%, are insufficient to avoid clear indications that a lower near-Earth penetration environment should be considered.

In a wider context, the less sensitive Explorer and Pegasus data compare well with lunar data[9], showing a near-Earth enhancement of the flux by less than an order of magnitude. At small masses, however, the interpretation of the MFE data in conjunction with data from Heos II[11] presents some difficulty, as the *in situ* measured flux is clearly lower than the lunar data of Morrison and Zinner[9]. Le Sergeant and Lamy[12], in considering the 'knee' of the lunar distribution, suggested that the derived primary microcrater distribution of Flavill *et al.*[13] supported the presence of two different interplanetary dust populations as first proposed by Brownlee *et al.*[14]. This work[13] decoded the obser-

ved microcrater distribution on lunar sample 12054 to remove the contribution from secondary craters, resulting in a flatter slope for the distribution in the region of 10^{-12} g. In a similar manner, an attempt has been made[15] to deconvolve the lunar data at lower masses leading to a reduction in the observed flux of a factor of 2 at a mass of 10^{-13} g and an order of magnitude at a mass of 10^{-16} g.

The need for such possible corrections to the microparticle influx derived from observed lunar microcrater distributions at masses $<10^{-12}$ g is now firmly supported by the MFE data. The experiment also exposes difficulty in understanding how the Prospero flux at mass 2×10^{-14} g is 2.5 magnitudes higher than the MFE data at mass 10^{-12} g. A logarithmic cumulative mass slope of ~1.5 is called for which is higher than any measured interplanetary or lunar microparticle flux data distributions. Although changing particle density could affect the comparison of penetration and such impact plasma experiments, the agreement between MFE and the Heos II plasma derived data argues against this, as does evidence from lunar microcraters where extremes of particle density or shape factor are shown to be atypical[16].

Impact craters recovered from Skylab windows[17] which showed evidence of aluminium microspheres in Earth orbit probably derived from upper-stage rocket firings, shows (Fig. 4) a flux distribution of anomalous slope and magnitude. The MFE data argue against this population being dominant at micrometre dimensions at least at the time of the STS-3 flight. The attribution of the four impacts to natural interplanetary sources, which is supported by chemical analyses, already yields a lower flux than previous data; we must conclude that at these dimensions the capture cell technique is likely to return a predominance of extraterrestrial material.

Acknowledgements and thanks are due to the NASA OSS-1 team and Ken Kissin, to J. L. Weinberg for development of the MFE flight opportunity, and to SERC for financial support. We also thank the applications laboratories of JEOL(UK), Cambridge Instruments, Philips Electron Optics and Hitachi Electron Optics for assistance and advice.

Proposed structures for poorly characterized phases in C2M carbonaceous chondrite meteorites

Ian D. R. Mackinnon* & Michael E. Zolensky

* Microbeam Inc., Mail Code SN4, NASA Johnson Space Center, Houston, Texas 77058, USA

Recent investigations of meteorite matrices using analytical electron microscopy and high-resolution transmission electron microscopy (HRTEM) have provided data on the structure and chemistry of poorly characterized phases (PCP)[1]. We suggest here that ~10 Å PCP, a dominant matrix variety, has a structure equivalent to iron-rich tochilinite [$6Fe_{0.9}S$ 5(Fe, Mg) $(OH)_2$] which consists of coherently interstratified mackinawite and brucite sheets[2]. In addition, we propose that ~17 Å PCP, previously described as an SBB-type mixed-layer structure[3], is a commensurate intergrowth of serpentine and tochilinite layers. A wide range of cation substitutions is possible within both tochilinite and serpentine–tochilinite structural types. We suggest that various forms of PCP observed in carbonaceous chondrites[4,5] are intergrowths of tochilinite, serpentine, serpentine–tochilinite and/or valleriite-type minerals[6].

Early HRTEM studies of the Murchison C2M meteorite[7,8] revealed that the fine-grained matrix (<1,000 Å) has a complex mineralogy containing unusual mixed-layer structures, including an ordered variety termed an SBB-type structure (The term SBB-type structure indicates an ordered arrangement of serpentine-type and brucite-type layers as originally suggested by Mackinnon and Buseck[3]. Tomeoka and Buseck[9] denote this phase '7-5-5'; the numbers refer to the lattice fringe spacings in a HRTEM image.) Subsequent work confirmed the presence of SBB-type phases in the Murray, Nogoya and Yamato-74662 meteorites[10,11] and indicated that Fe may be abundant in this type of phase. Fine-scale chemical analyses (<500 Å) showed that Ni, Al, Si and S are also present[12]. Mackinnon[12] suggested that SBB-type structures in the Mighei matrix may be a variety of PCP or PCP intergrown with matrix phyllosilicates. Subsequently, detailed HRTEM studies by Tomeoka and Buseck[9,13] have shown that Mighei matrix PCP includes (1) coherent intergrowths of S-type (~7 Å) and B-type (~5 Å) layers as an SBB-type structure, (2) disordered ~5 Å and ~7 Å layers and (3) an ordered ~5 Å phase. Recent lattice image studies of C2M matrices[13,14] have emphasized an ordered ~5 Å phase in their analyses of PCP, although there is some ambiguity in the terminology used.

A compilation of data (colour, optical anisotropy, reflectivity, hardness and morphology) for typical PCPs from C2M meteorites[4,5,15] and for terrestrial tochilinite[16] shows that in all cases, properties of fibrous PCP match the bulk properties of fibrous tochilinite. A similar case can be made for the many varieties of PCP and tochilinite. Electron microprobe analyses[5] have shown that PCP morphologies are correlated with composition: a massive, sulphur-rich Fe, Ni phase; a granular to formless Mg, Si-rich Fe sulphide and a fibrous Fe, Ni phase with intermediate amounts of Si, S and C. Tochilinite is usually fine-grained in terrestrial occurrences and is difficult to analyse accurately; representative microprobe analyses from two localities are given in Table 1. For comparison, columns 3 and 4 of Table 1 also show microprobe analyses for typical PCP phases in C2M chondrites. In general, major element chemistry for tochilinite agrees well with analyses of PCP from C2M meteorite matrices.

In their study of the ~10 Å PCP phase, Barber *et al.*[1] present a set of interplanar spacings from a (presumed) ordered single crystal. These spacings, obtained from conventional electron diffraction and optical transforms of structure images, are not as precise as X-ray powder diffraction data. Nevertheless, a compilation of interplanar spacings for tochilinite[16] and the ~10 Å PCP described by Barber *et al.*[1] show remarkable agreement (Table 2). One exception in this compilation is the 7.7 Å (and perhaps 2.9 Å) spacing(s), which may be due to a small amount of serpentine-type mineral interstratified with the ordered ~10 Å PCP phase. For comparison, Table 2 also gives interplanar spacings for lizardite[17] and valleriite[18]. X-ray patterns from a fibrous variety of PCP in Murchison also give a sharp line at 5.4 Å and a weaker line at 2.72 Å (ref. 4). Barber *et al.*[1] suggest a chemical formula of $Fe_{1.4}SO_{1.3}$ for ~10 Å PCP using electron energy loss spectroscopy analysis. This method is not as precise as conventional electron microprobe analysis[1],

Table 1 Reported microprobe analyses of terrestrial tochilinites and meteoritic PCPs

	Tochilinite[16]		Meteoritic[5]	
Wt%	1	2	3	4
Fe	44.92	35.27	40.03	41.97
Mg	10.94	13.24	0.42	0.34
Al	—	4.27	0.28	0.05
S	21.73	24.33	17.00	20.40
Cr	—	—	2.26	—
Ni	—	—	7.70	5.8
C	—	—	2.2	2.4
Other	—	—	1.33	0.45
Total	77.59	77.11	71.22	71.41

'Other' includes minor amounts of Ca, K, P and Si. Columns 3 and 4 are PCP type I and PCP from a CM clast in the Jodzie meteorite, respectively[5]. Analyses from ref. 5 are converted to wt% elements to facilitate comparison with tochilinite values. All columns do not add up to 100% due to the presence of structural water which has not been analysed. For example, in column 1, a calculated (OH) content of 20.99 wt% yields a total analysis of 98.58%[16].

but within the relative error of the technique (~16%) and expected chemical variations (see below), there is agreement with the accepted tochilinite formula. Indeed, based on this analysis, Barber *et al.*[1] suggest that ~10 Å PCP may be the fibrous mineral described by Jambor[16], subsequently identified as tochilinite[2].

Selected area electron diffraction studies[2] show the complexity of valleriite- and tochilinite-like minerals, which consist of alternating sulphide and brucite sheets. Figure 1*a* shows an idealized model of the tochilinite structure along the *c* axis. In this structure, brucite-type sheets alternate with mackinawite-type sulphide sheets to form a C-centred unit cell with dimensions $a = 5.37$ Å, $b = 15.60$ Å, $c = 10.72$ Å and $\beta = 95°$ (ref. 2). The mackinawite sheet consists of FeS_4 tetrahedra in a unique edge-shared arrangement. The relative rotation of neighbouring brucites sheets is 22°, while each brucite sheet is also rotated relative to the origin of the mackinawite sheet[2].

Individual sheets within the tochilinite structure can be considered as being structural units bound together primarily by hydrogen bonds. Consequently, cation substitutions common to brucite and mackinawite can be expected for the compositional range of tochilinite. Chemical formulae on the right-hand side of Fig. 1*a* show the major cation substitutions expected within each sheet of the tochilinite structure. The mackinawite sheet can accommodate a high concentration of vacancies as well as substitutions of other cations[19]. Analyses of Kamaishi mine samples[19] show that the tochilinite structure allows significant Cu substitution within individual mackinawite sheets. However, higher contents of Cu within the sulphide sheet stabilize the valleriite structure. In valleriite, the sulphide sheet is a derivative of the cubic close-packed chalcopyrite structure containing edge-shared Cu, Fe tetrahedra[20]. Analyses of other tochilinites from Kamaishi indicate that considerable amounts of Fe and minor amounts of Al and Ca may substitute into the brucite sheet[19]. Indeed, the replacement of Fe for Mg in the brucite structure is a well-documented phenomenon and may range from 6 to 72 mol% $Fe(OH)_2$ (ref. 21 and refs therein); the latter is known as amakinite[22]. Within tochilinite, vacancies in the sulphide sheet produce a net negative charge, but this can be balanced by the presence of trivalent Fe in the brucite sheet[2,19]. Addition of minor amounts of Ni within the sulphide sheet may allow unusual charge balance distributions which may depend on the environment of formation. On the basis of carbonaceous chondrite chemical analyses[4,5], we suggest that meteoritic tochilinite will tend to form iron-rich tochilinite structures with alternating mackinawite and amakinite sheets.

HRTEM observations show that ~10 Å PCP forms sinuous, curved, rolled and 'corrugated' structures in the Mighei matrix[1,13,14]. These observations of layer curvature can be explained by the degree of misfit between two sheets of different

sizes. Within individual sheets, cation substitution will change the degree of misfit, and thus the radius of sheet curvature will also vary. The greatest degree of misfit is along the *a* axis of tochilinite[2]. Therefore, varieties of tochilinite curved about the *a* axis will be most common. In addition, the presence of edge dislocations in a plane parallel to the *a* axis of brucite provides a mechanism for the lattice to curve about *a* (ref. 23). Thus, buckling of the tochilinite structure normal to *c*, but not parallel to *a*, will produce a corrugated structure similar to antigorite[24]. However, unlike antigorite, the mechanism of misfit need not be periodic within the brucite sheet of tochilinite. Thus, corrugations within tochilinite should be limited. Buckling of tochilinite, in concert with cation substitution, may produce a three-dimensional incommensurate structure with layers loosely held

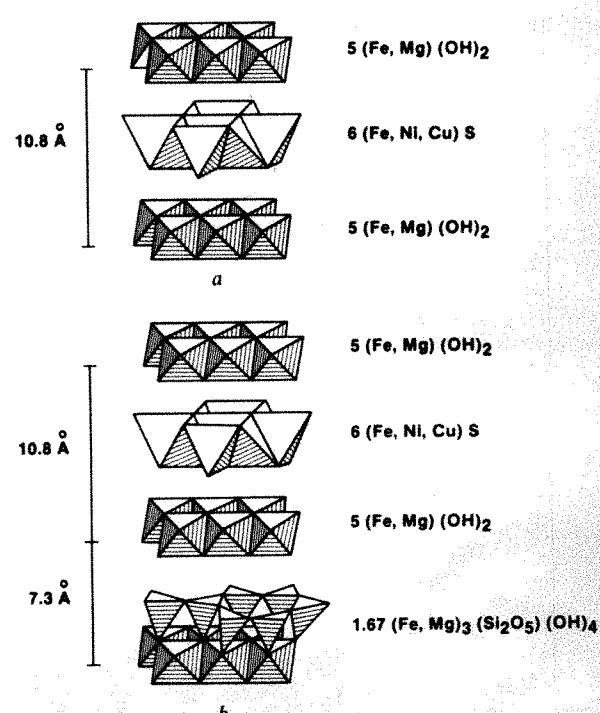

Fig. 1 Schematic models of proposed structures for two predominant types of PCP in C2M meteorites: *a*, a tochilinite structure; *b*, a serpentine–tochilinite structure.

together by hydrogen bonding. Complex structural adjustments of this nature will result in equally complex HRTEM images of meteoritic tochilinite as shown by Barber *et al.*[1] and Tomeoka and Buseck[13,14].

We further suggest that the tochilinite structure is a subunit of the SBB-type (~17 Å PCP) phase[9]. HRTEM images of ~17 Å PCP show a distinctive alternation of ~7 Å and ~5 Å lattice fringes of the type SBB (refs 4, 25) or 7-5-5 (ref. 11). These HRTEM images were initially interpreted as ordered alternations of serpentine-type (S) and brucite-type (B) layers on the basis of structural arguments and matrix bulk chemistry[3,25]. A Si-rich component of some PCPs is also inferred from their relatively high Si contents[5,12]. A combination of serpentine and tochilinite layers (held together by hydrogen bonds) gives a basal periodicity between ~17 and ~18 Å, depending on the strength of interlayer bonds and/or chemistry. A schematic model of this proposed serpentine–tochilinite structure is shown in Fig. 1*b*. In this particular case, the planar lizardite layer conforms with the observed planar layer structure of an SBB-type PCP shown in Figs 4 and 5 of ref. 25. Compositional variations within the serpentine layer may also induce a corresponding modulation of the overall structure[25]. Thus, serpentine–tochilinite structures with a higher Mg content in the 7 Å layer tend to form curved or cylindrical structures as shown in Fig. 1 of ref. 8. However, structural misfit between the mackinawite and brucite sheets of tochilinite can also produce curved, sinuous or 'turbostratic' structures. Therefore, we suggest that variations in *c* axis structure images of serpentine–tochilinite are due to the misfit of octahedral and tetrahedral sheets within both tochilinite and serpentine layers and may also correspond to subtle variations in composition along the layers.

An indication that serpentine–tochilinite may occur in terrestrial rocks comes from studies of a calcite healed breccia in limestone at the Grace Mine, Pennsylvania[16]. In these samples, some regions containing tochilinite show a distinctive compositional zoning in which optically darker bands are rich in silica and relatively low in sulphur. Jambor[16] suggests that these zones consist of intimately interlayered tochilinite and serpentine. Microprobe analyses from these regions are similar to analyses of Si-rich PCP in C2M meteorites[5]. We suggest that a detailed HRTEM investigation of Grace Mine samples will provide evidence for a terrestrial occurrence of serpentine–tochilinite. Tochilinite has also been found with a valleriite-like carbonate phase[6]. The presence of carbon in PCPs was suggested by Ramdohr[15] and concentrations as high as 8 wt % have been analysed in PCPs[5]. On the basis of these analyses and the proposed structures of two types of PCP, we suggest that valleriite-type layer structures may also occur in C2M matrices.

Conclusions regarding the petrogenesis of meteoritic tochilinites and related structure types must be developed with caution. Significant compositional differences are apparent between terrestrial and meteoritic tochilinites. For example, Ni is absent from many terrestrial occurrences of tochilinite[22], although we consider it possible that minor amounts of Ni can be substituted into the mackinawite sheet. (An indication that Ni-rich tochilinite occurs in terrestrial rocks has recently been given by van der Vusse and Powell[26].) The presence of Ni in tochilinites may prove to be an indicator of the environment of formation. In suitable conditions, substitution of other elements (for example, K, P) may also be possible in interlayer sites. Terrestrial tochilinite has been largely ignored by petrologists partly because of its small grain size and (presumed) limited occurrence. However, PCPs (and therefore, meteoritic tochilinites) constitute a significant part of an important group of meteorites, and we urge a strong commitment towards an understanding of phase relations and probable formation mechanisms for tochilinite and serpentine–tochilinite. Furthermore, experimental data obtained in conditions pertinent to carbonaceous meteorite formation should provide significant insight into the origin and evolution of C2M meteorite matrices.

Discussions with J. Jambor and comments on a draft manuscript by F. J. M. Rietmeijer and D. S. McKay are greatly appreciated. Constructive reviews were given by D. J. Barber and H. Y. McSween. M.E.Z. is a NRC Research Associate at JSC.

Does the photochemistry of the troposphere admit more than one steady state?

Warren H. White & David Dietz

Center for Air Pollution Impact and Trend Analysis, Washington University, St Louis, Missouri 63130, USA

Nitrogen oxides are released to the troposphere primarily as NO and NO_2, relatively insoluble gases which are not effectively scavenged by clouds and precipitation[1]. Nitrogen oxides are removed from the troposphere primarily as HNO_3, the highly soluble product of reactions with O_3 and various free radical species[2]. The NO_x (= NO + NO_2) removal rate thus depends on the oxidizing potential of the troposphere, which in turn is sensitive to the NO_x concentration[3]. Here we demonstrate that in certain conditions the NO_x removal rate is a non-monotonic function of NO_x concentration. A consequence is that NO_x emission rates within a critical range can support two or three different steady-state NO_x concentrations. The 'nonstandard' steady states are characterized by low concentrations of ozone and radicals, and by high accumulations of the trace gases these normally scavenge. The emission rates required to support such alternative steady states appear to be somewhat in excess of present levels.

The possibility of multiple steady states is illustrated here in a zero-dimensional (box) model, transport being neglected to emphasize the essentially chemical nature of the phenomenon. Conditions in the box are chosen to be representative of the free troposphere[4]: 273 K, 1.7×10^{19} molecules cm^{-3} (4 km altitude), and 3,000 p.p.m. water vapour.

Table 1 presents the gas-phase reaction scheme, condensed where possible by the elimination of intermediates with unambiguous fates. The rate constants are adapted from Hampson and Garvin[5] and Chameides[6]; photolysis rates represent equinoctial diurnal averages at 45° N. The effects of heterogeneous reactions are lumped into the first-order rates for physical removal, which are presented in Table 2 together with external source strengths. The degree of nonlinearity in the dependence of NO_x removal on NO_x concentration, and hence the potential for multiple steady states, is controlled by the relative importance of the (nonlinear) chemical and (linear)

Table 1 Reaction scheme used in calculations

	Reaction	Rate coefficient
R1	$NO+O_3 \rightarrow NO_2$	1.5 (+1)
R2	$NO_2+h\nu \rightarrow NO+O_3$	1.6 (−1)

R20	$H_2O_2+HO \rightarrow HO_2$	9.5 (+2)
R21	$H_2O_2+h\nu \rightarrow 2HO$	3.7 (−5)
R22	$HO_2+HO \rightarrow$ —	4.4 (+4)

Rate coefficients are adapted from Hampson and Garvin[5] and Chameides[6] for the following conditions: density = 1.7×10^{19} molecules cm^{-3} (z = 4 km), T = 273 K, water vapour = 3,000 p.p.m., equinox at 45° N. Numbers in parentheses are powers of 10; units are min^{-1} or p.p.m.$^{-1}$ min^{-1}.

physical removal pathways. Accordingly, two sets of physical removal rates are considered, one representing relatively long (500 days for NO), the other relatively short (10 days for NO), lifetimes against physical removal. The source strengths of O_3, CO, C_2H_4 and CH_2O in Table 2 are obtained by distributing the estimated global emissions uniformly (with respect to mixing ratio) throughout the troposphere. The source strength of NO_x is varied as a parameter, the composition of the emissions being held constant at 95% NO and 5% NO_2. Only the methane concentration is externally imposed, at 1.6 p.p.m.; all other concentrations are determined by the equilibration of sources and sinks.

Figure 1 shows how the calculated steady state varies with NO_x concentration for a weak physical sink. Photolysis of O_3(R7) yields HO, which reacts with CO and hydrocarbons (R8, R9, R10) to yield HO_2 and CH_3O_2, which oxidize NO (R13, R14) to NO_2, which photolyses (R2) to yield O_3. In the natural troposphere NO_x is the limiting reactant for the photochemical production of O_3 (ref. 3), and the oxidizing potential of the troposphere increases with increasing NO_x concentration. Because the photostationary ratio of NO_2 to NO increases with O_3 (ref. 7), NO_2 must increase with NO_x as long as O_3 does. As the ratio of NO_2 to CO and hydrocarbons increases, however, so does interdiction of the photochemical chain by R15, a non-productive sink for HO. The NO_2 concentration cannot continue to rise indefinitely without reducing the O_3 yield on O_3 photolysis below break-even. At some point, therefore, O_3 must begin to decrease with further increases in NO_x. Figure 1 shows that a break in fact occurs in the neighbourhood of 1 part in 10^9 (p.p.b.) NO_x. Increases in the NO_x concentration beyond this level produce a decrease in the ozone concentration and an even stronger decrease in free radical concentrations, as the growth of sinks (R13, R15) compounds the decline of the source (R7). Similar calculations by Stewart *et al.*[8] and Hameed *et al.*[4] have yielded the same general pattern, with O_3 and HO peaking at slightly lower NO_x concentrations. An analogous nonlinearity in the chlorine chemistry of the stratosphere has been demonstrated by Prather *et al.*[9] and Fox *et al.*[10].

Figure 2 shows the effect of the break in photochemical reactivity on the NO_x removal rate. As a function of NO_x

Table 2 External source and sink strengths used in calculations

	Source Q (p.p.b. min^{-1})	Sink $1/R$ (days)	
		Weak	Strong
NO	Variable	500	10
NO_2	Variable	50	10
O_3	3×10^{-4}	50	10
CO	7×10^{-4}	500	500
C_2H_4	5×10^{-6}	50	10
CH_2O	6×10^{-7}	50	10
CH_4	Concentration imposed		
HO	0	10	1
HO_2	0	10	1
CH_3O_2	0	10	1
H_2O_2	0	10	1
NO_3	0	10	1
HNO_3	0	10	1

Source strengths of O_3, CO, C_2H_4 and CH_2O represent estimated global emissions[6,19,20], distributed uniformly (with respect to mixing ratio) throughout the troposphere. The source strength of NO_x is varied as a parameter, with the composition of the emissions held constant at 95% NO and 5% NO_2. The methane concentration is fixed at 1.6 p.p.m. Sink strengths, R, are the first-order coefficients for removal by rainout and other mechanisms not included in the reaction scheme. Two sets of sink strengths are used, presented here in terms of lifetimes, their reciprocals.

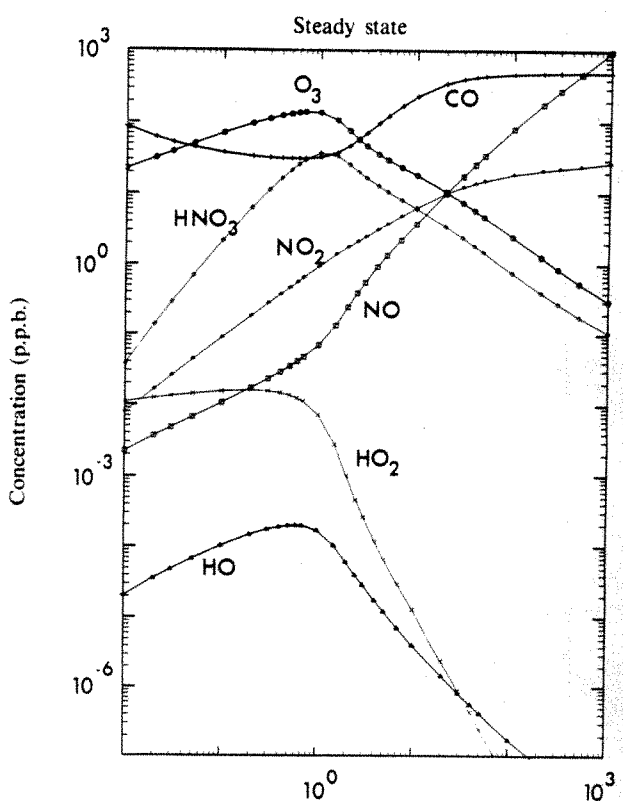

Fig. 1 Calculated steady state of the free troposphere as a function of NO_x ($=NO+NO_2$) concentration. Conditions are those of Tables 1 and 2, with a weak physical sink.

concentration, the NO_x sink has a relative maximum where the reactivity peaks, and a relative minimum where oxidation and physical removal are of comparable importance. A similar pattern is observed for a strong physical sink, with the photochemical peak slightly attenuated and the transition to predominantly physical removal occurring at lower NO_x concentration. The effect of holding the CO concentration fixed at 150 p.p.b., shown in Fig. 2 for a weak sink, is to accentuate

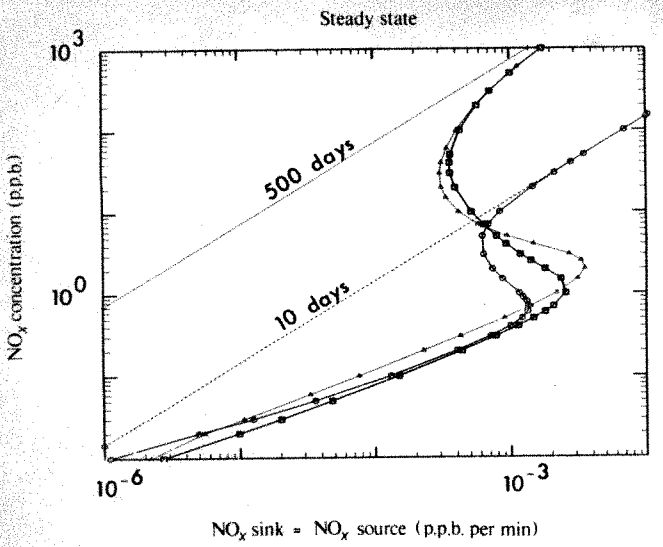

Fig. 2 Calculated steady-state NO_x ($=NO+NO_2$) concentration in the free troposphere, as a function of NO_x source strength. The heavy curves are calculated from the reaction scheme of Table 1 and the source strengths of Table 2; the one marked with circles corresponds to the strong physical sink of Table 2, the one marked with squares to the weak physical sink. The light curve (marked with triangles) shows the effect of fixing the CO concentration at 150 p.p.b., for the weak physical sink. The sloping lines, labelled by the lifetime of NO against physical removal, show the linear relationship of concentration to emissions in the absence of photochemical oxidation.

both peak and trough in the sink strength. (The free-floating calculations underestimate the CO concentration, presumably due to gaps in the inventory of emissions (compare refs 6 and 11). The non-monotonic dependence of the NO_x sink on NO_x concentration is, in sum, a fairly robust feature of the calculation. The principal limitation of this result arises from its basis in diurnally averaged photolysis rates, which do not allow for the buildup of NO_3 in the dark. The rapid equilibration of NO_3 with soluble N_2O_5 provides, in the boundary layer and in clouds, a potentially significant night-time pathway for the oxidation and removal of NO_x (refs 2, 12). The calculations presented here are therefore most relevant away from clouds in the free troposphere where, in the absence of liquid water, NO_3 and N_2O_5 simply accumulate overnight and revert to NO_x at daybreak.

It is clear from Fig. 2 that dissimilar NO_x concentrations can yield similar NO_x removal rates. As the steady-state NO_x concentration is determined by equilibration of source and sink strengths, this means that a given rate of emission may support more than one steady-state concentration. Consider a source strength for NO_x of 1 part in 10^{12} (p.p.t.) per min, for example, in combination with a strong or weak physical sink. Figure 2 shows that three distinct steady states are possible in either situation. The low-NO_x state is stable, and is characterized by concentrations which are not uncommon over industrial regions: 0.40 p.p.b. NO_x and 64 p.p.b. O_3 for a strong sink, 0.36 p.p.b. NO_x and 120 p.p.b. O_3 for a weak sink. The middle-NO_x state is unstable, and is therefore of no practical interest. The high-NO_x state is characterized by concentrations not presently seen in the free troposphere: 13 p.p.b. NO_x and 4 p.p.b. O_3 for a strong sink, 500 p.p.b. NO_x and 0.5 p.p.b. O_3 for a weak sink. The high-NO_x state is stable, however, and would be expected to persist once established in a sufficiently large region. A shift from the low-NO_x state to the high-NO_x state would profoundly change the reactivity of the troposphere, permitting the accumulation of CO and other trace gases presently scavenged by O_3 and HO (ref. 13). (One of the gases to accumulate would be CH_4, assumed in our calculation to remain at constant concentration—because of this and other neglected long-term feedbacks, the high-NO_x solution is best viewed as a quasi-steady state whose ultimate fate is difficult to predict.) An emissions transient capable of shifting a large region into the high-NO_x state is not outside the realm of possibility; Crutzen and Birks[14] calculate that nuclear war could inject of the order of 100 p.p.b. NO_x into the upper troposphere between 40° and 60° N.

In the conditions considered here, multiple steady states become possible at NO_x source strengths above 0.3–0.6 p.p.t. min^{-1}, where the minimum NO_x concentration is $\geq$0.2 p.p.b. Actual NO_x concentrations reach the 0.2 p.p.b. threshold over industrial continents[2], but tend to be substantially lower over remote areas[15]. Actual NO_x emissions are currently estimated[2] to average about 30×10^9 molecules $cm^{-2}\,s^{-1}$ at 45 °N. Much of this originates within the boundary layer, so that the effective source to the free troposphere depends on the rapidity and nature of exchange between the two layers[16]. Even if they were distributed uniformly in the vertical, however, such emissions would correspond to a source strength of only 0.1 p.p.t. min^{-1} supporting a unique steady-state NO_x concentration of ~0.1 p.p.b. It appears likely, therefore, that current emissions do not quite suffice to support nonstandard steady states on the zonal scale considered here. This is not a firm conclusion, because the viability of alternative steady states is sensitive[10,17] to details of atmospheric mixing which are poorly understood. It should also be noted that natural emissions of NO_x are rather uncertain[2], and that anthropogenic emissions are rapidly increasing[18].

Synthesis of marine humic substances from unsaturated lipids

G. R. Harvey, D. A. Boran, S. R. Piotrowicz & C. P. Weisel

National Oceanic and Atmospheric Administration, Atlantic Oceanographic and Meteorological Laboratory, 4301 Rickenbacker Causeway, Miami, Florida 33149, USA

The origin and structure of the dissolved blue-fluorescent yellow organic substances (Gelbstoff) in seawater have long eluded characterization[1]. The fact that this class of organic matter, which comprises 10–50% of the organic carbon in the sea[2], became known as marine humus (fulvic and humic acids) has led to much confusion because of the implied relationship with soil humus[3]. Based on chemical and spectral studies of oceanic and coastal humus we recently proposed a class structure and a mechanism

by which these marine humic substances could form[2]. The hypothesis was that they are water soluble, aliphatic organic acids formed by the autoxidative cross-linking of two or more unsaturated lipids released into seawater. We have now confirmed that hypothesis by allowing pure marine lipids and a diatom to autoxidize in seawater in the laboratory. We report here that the yellow substances obtained are similar in all respects to marine humus.

The syntheses were conducted in coastal Miami seawater from which the humus was removed by extraction with Amberlite XAD-2 at *p*H 2 (refs 2, 4, 5): 10 litres of this water were adjusted to *p*H 8.2 in an open steel container. About 50–100 mg of the particular lipid, dissolved in 5 ml of ethyl ether, were added in 5 mg aliquots to the seawater every 0.5 h until the final concentration was 5 mg l^{-1}. Stirring was continuous throughout the 24–100 h duration of the experiment with the water fully exposed to air and laboratory light. To terminate the synthesis the water was acidified to *p*H 2 and after 1 h passed through a 75 cm^3 column of XAD-2 at 60 ml min^{-1}. Isolation of the products from the resin with methanolic ammonia was by the same process as described elsewhere[2,4,5]. The pure lipids used were trilinolein, triolein, glyceryl-1,3-dioleate and glyceryl-1-palmitate-2,3-dioleate. The yields were generally greater than 50 mg. Another synthetic, fulvic acid, was made by allowing freeze-dried *Skeletonema costatum*, a marine diatom, to stir in extracted seawater for 1 week. Fully saturated tripalmitin and tristearin produced no product with the properties of marine humus.

The products obtained from the pure unsaturated lipids and the lipids in the diatom[6] were pale-yellow powders freely soluble in water but insoluble in ether. An elemental analysis of the product from trilinolein was: C, 45.73%; H, 6.71%; N, 0.86%. These values compare well with those of a fulvic acid from the Sargasso Sea[7]. The $\delta^{13}C$ of this material was −19.7‰, which compares well with the isotope values of three marine fulvic acids we isolated from the Gulf of Mexico, that is, −20.6, −21.5 and −22.0‰. Interestingly, the $\delta^{13}C$ of the trilinolein used was −28.1 but we do not know the cause of this large fractionation. Small amounts (3–5 mg) of synthetic humic acids precipitated at *p*H 2 from the trilinolein reaction mixtures.

In all cases, the proton NMR spectra of the synthetic humic substances could be matched with one or more spectra obtained from our collection of oceanic humus[2] (Fig. 1). The extent of cross-linking and heteroatom incorporation can be estimated from the relative widths of the methylene (1–2.5 p.p.m.) and H–C–O– (3–4 p.p.m.) peaks in the NMR. The IR spectrum of the product of trilinolein autoxidation is superimposable on the spectra of marine fulvics. In addition to the yellow colour of both the natural and synthetic substances, irradiation at 350 nm produces the same broad fluorescence emission between 350 and 650 nm, indicating that the same chromophores are present. Gel permeation chromatography at *p*H 4, 6 and 8 using both acetate and phosphate buffer eluents (Varian TSK 2000 SW and Sephadex G-25 columns) gave retention times of synthetic and natural fulvics within 5% of each other, indicating similar size and functionality. Although not strictly comparable, polyethylene glycol molecular weight standards indicated a molecular weight range mainly between 600 and 800, which is consistent with our proposed structures. These molecular weight results should be treated with caution because the standards were not the exact same class of compounds[8].

We have also observed the formation of synthetic marine humic substances by quantifying the development of the zinc complexing ability of seawater containing an unsaturated lipid. We have shown that marine humus is a good complexer of copper and zinc as detected by differential pulse anodic stripping voltammetry (DPASV)[9,10]. Trilinolein (2.5 mg l^{-1}) was added to aged Gulf Stream water which had little or no complexing capacity for Zn. The Zn signal was monitored periodically for 38 h by standard additions followed by DPASV analysis. The complexing capacity increased from 0.0 at 4 h to 0.5 nmol kg^{-1} at 8 h to a total of 3 nmol kg^{-1} at 38 h. The more saturated glyceryl 1,3-dioleate-2-palmitate required 48 h before any increase in Zn complexing capacity was observed. The fully saturated tripalmitin does not autoxidize and did not increase the Zn complexing capacity of the seawater. The different times required by the two lipids to autoxidize and develop Zn complexing ability are related to the number of free radical reactive sites. The synthetic fulvic acid from trilinolein was also shown to protect photosynthetic plankton from copper inhibition to the same degree as a natural marine fulvic[11].

The above evidence supports our proposed mechanism of formation and structure of oceanic humus. Humic substances isolated from estuarine and coastal waters are generally admixtures from marine, freshwater and dissolved soil sources and can have different properties from those described for ocean water. The word 'structure' in this context does not refer to a single compound but a closely related family of compounds whose properties can be described by one or two structural formulas as is the case with coal and lignin.

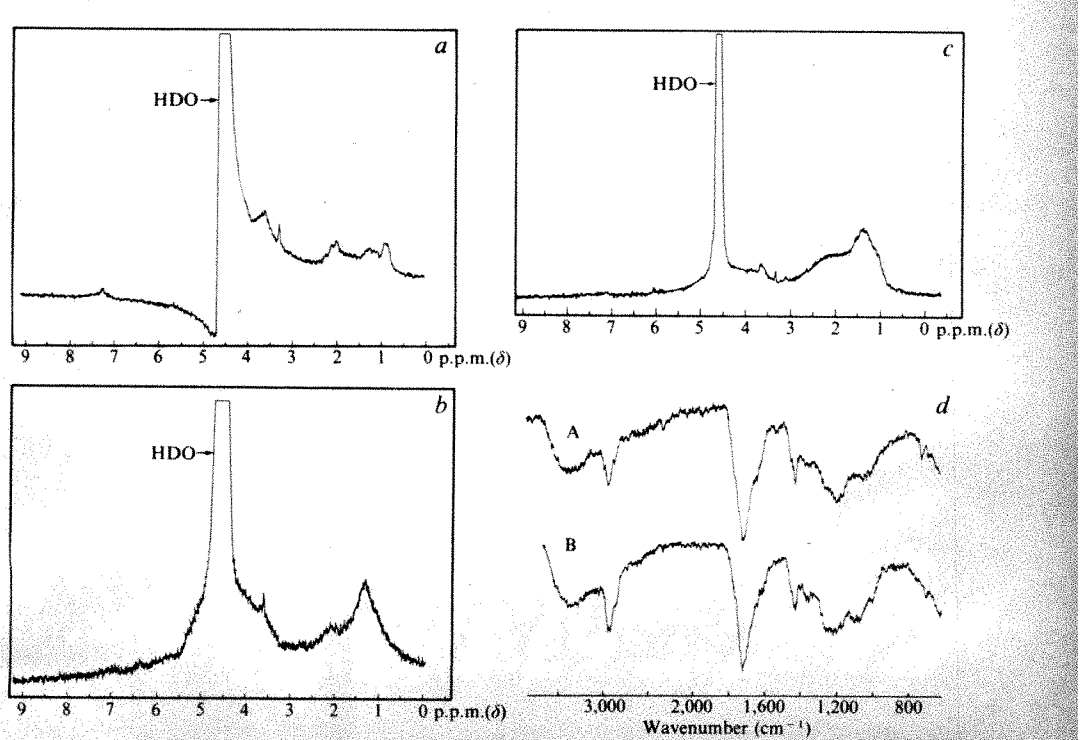

Fig. 1 Proton NMR spectra of the synthetic fulvic acids from trilinolein (*a*), glyceryl-1,3-dioleate-2-palmitate (*b*), and an open ocean fulvic acid (*c*). The IR spectra of the methyl esters of the marine fulvic acid (A) and the trilinolein product (B) are shown in (*d*). Note the greater amount of unaltered methylene protons (1.2 p.p.m.) in *b* in comparison with *a*.

The reactions described here are extracellular examples of the enzyme-controlled cyclization of arachidonic acid (20:4) to prostaglandins[1,2] and the random free radical autoxidation of cellular unsaturated lipids, a process implicated in many pathologies[13].

We thank M. Springer-Young and B. Wrenn for laboratory assistance. The carbon isotope data were provided by J. and P. Gearing. The Skeletonema was supplied by R. R. L. Guillard. C.P.W. thanks the US National Research Council for a post-doctoral fellowship. This work was funded by NOAA's Office of Marine Pollution Assessment.

Ciliated protozoa associated with oceanic sinking detritus

Mary Wilcox Silver*, Marcia M. Gowing*, David C. Brownlee†‡ & John O. Corliss†

* Marine Sciences, University of California, Santa Cruz, California 95064, USA
† Department of Zoology, University of Maryland, College Park, Maryland 20742, USA

In the past decade, protozoa have been recognized as ubiquitous residents of the upper waters of the sea, where they have key roles in detrital and producer food webs[1–4]. In contrast, protozoa are almost unknown from aphotic depths, where food chains presumably are supported by detritus. We show here that ciliate protozoans do accompany sinking detritus to bathypelagic depths. In the productive northeastern Pacific Ocean, the biomass of ciliates on particles settling between the surface and 2,000 m far exceeds the biomass of bacteria, which are the only widely recognized detrital microorganisms in deep pelagic communities. Although absolute numbers of ciliates decline below the euphotic zone, their concentrations (number per g detritus) drop only slightly by 2,000 m. Taxonomic data and patterns of abundance[5] indicate that the ciliates are endemics and not remnants of surface colonists, and that the deep sea is a favourable environment for them. Their high concentrations, possibly together with other smaller protozoa, indicate that protists may control bacterial mineralization rates on sinking particles, thereby regulating the vertical distribution of many biologically active elements in the sea.

We collected sinking particles in drifting, preservative-filled sediment traps[6] deployed in the high productivity, eastern boundary current off central California (vertical transport and exchange of materials in the upper waters of the ocean, VERTEX I) and Mexico (VERTEX II and III). Bacteria and ciliates in the traps were counted using methods outlined in Fig. 1. The microorganisms we found were probably associated with the trapped particles, as the sinking rates of individual cells would be insufficient to account for their numbers in the collections.

‡ Present address: Institute of Marine Resources, A-018, Scripps Institute of Oceanography, La Jolla, California 92093, USA.

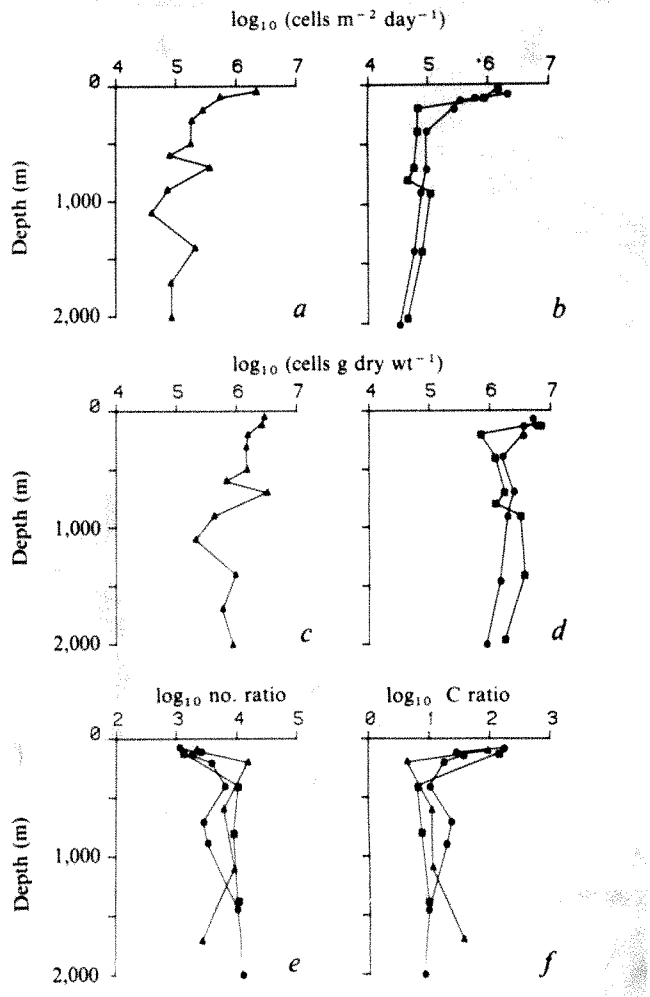

Fig. 1 Microorganisms (numbers and biomass) from sediment traps in the northeastern Pacific Ocean during VERTEX cruises. During VERTEX I (▲), traps were deployed from 26 August 1980 to 8 September 1980 at 35° N; 123° W, during VERTEX II (■) from 27 October 1981 to 17 November 1981 at 17° N; 109° W, and during VERTEX III (●) from 9 November 1982 to 30 November 1982 at 16° N; 107° W. Because they collect for several weeks, traps measure the time-averaged standing crop on sinking particles, or 'flux' of organisms: numbers m^{-2} day^{-1}. Ciliates in the traps were counted and sizes measured at ×400 in 3–5 aliquots in settling chambers with an inverted phase microscope. Specimen condition was checked in aliquots prepared for transmission electron microscopy (TEM). Protargol silver stained[13] specimens were identified using oil-immersion, bright-field optics. Bacteria stained with diamidinophenylindole[14,15] were counted on 0.2 μm Nuclepore filters at ×1,188 with oil immersion optics from three aliquots of trap material and sizes measured in TEM preparations[16]. Carbon content was estimated using carbon-volume relationships from the literature[17,18]. *a*, Ciliate flux during VERTEX I. *b*, Ciliate flux during VERTEX II and III. *c*, Ciliate flux per g dry weight of trap material from VERTEX I. *d*, Ciliate flux per g dry weight of trap material from VERTEX II and III. *e*, Ratio of numbers of bacteria to numbers of ciliates in the trap material from the three cruises. *f*, Ratio of biomass (cell carbon: see above) of ciliates to biomass of bacteria in the trap material from the three cruises.

Ciliates were most common in the shallowest traps, but flux remained above 10^4 cells m^{-2} day^{-1} at all depths (Fig. 1*a*, *b*). The decrease in trap-collected ciliates with depth largely resulted from reduction in the quantity of sinking particulate matter, since numbers per unit dry weight declined only slightly with depth (Fig. 1*c*, *d*). Ciliate flux showed no consistent reduction in the pronounced oxygen minimum between 600 and 950 m on VERTEX I (ref. 7) and between 100 and 1,000 m on VERTEX II (ref. 8) and III (W. Broenkow, personal communication). Although bacteria outnumbered ciliates by 10^3–10^4 (Fig. 1*e*),

Table 1 Ciliates* associated with vertically sinking particles† collected during VERTEX II‡ in the Pacific off central Mexico

Depth	30 m	120 m	1,950 m
Numerical dominants	(1) Oligotrichs (such as *Strombidium, Tontonia*) (2) Haptorids (such as didiniids)	(1) Scutico-ciliates (2) Protosto-matids (such as *Metacystis*)	(1) Protosto-matids (such as *Metacystis*) (2) Scutico-ciliates (3) Nassulids (4) Oligotrichs (such as *Strombidium, Strobilidium*)
No. of species per 50 specimens	19	10	15
No. of species shared between adjacent depths	0		5

At our sampling site, temperature at 30 m was 38.5 °C, at 120 m was 14.0 °C, and at 1,950 m was 2.3 °C and water depth was ~3,500 m. Major ciliate orders are listed and species diversity is indicated. Specimens were classified using the taxonomic scheme of Corliss[9].

* Some fixation-related shrinkage occurred and loss of especially delicate cells was possible; controls for possible cellular lysis in sediment traps are not available. Predeployment checks of net-collected, surface populations with a variety of fixatives, however, indicated our trap preservation solution caused comparatively little ultrastructural (TEM) damage to cells. (Species lost due to fixation could affect the apparent 'endemism' to an unknown extent. Quantitatively, however, losses would result in the underestimation of ciliate importance in our samples.)

† We assume these ciliates represent populations accompanying vertically sinking particles—that significant amounts of allochthonous particulates were not introduced at mid-depth by horizontal advection. A common surface source for the three traps was indicated by their similar phytoplankton debris. Furthermore, current flow measurements did not suggest a physical basis for the largest vertical species change—that found between populations in the two upper traps: the measured maximum current sheer[8] and the predicted sinking speed of marine snow[19] indicate a horizontal displacement of no more than 30 km between sources for the two traps. Most likely, species changes in the living microbial populations resulted from environmental stresses, particularly the low oxygen levels at mid-depth. Moreover, chemical analyses do not indicate significant new inputs of particulate materials at the two deeper trap depths[20].

‡ Although we did not perform such a detailed species analysis on materials from VERTEX I or III, a preliminary study of ciliates from the Central California Site (I) showed similar depth-related changes as were observed at the Mexican site (II) and similar ciliate species arrays at depth.

ciliate biomass exceeded that of bacteria due to the relatively large size of the protozoa (usually 10–150 μm compared with < 1 μm, respectively). The ciliate dominance was most pronounced near the surface, but ciliate biomass still exceeded that of bacteria in the deepest traps (Fig. 1*f*).

Taxonomic composition of ciliate populations changed markedly with depth (Table 1). Species richness was highest in the near-surface trap, lowest in the oxygen minimum zone, and intermediate at the greatest depth. The ciliate taxa in the shallowest trap were similar to those from the euphotic zone, but shared no species with the deeper populations. The two deep-water ciliate samples contained taxa not normally reported in lists of planktonic organisms, possessed some of the same species, and included forms that represent not only new species and genera but even higher ciliate taxa (ref. 5 and D.C.B. and J.O.C., manuscript in preparation; also see the classification used in ref. 9).

Our VERTEX results point to several conclusions. First, protozoa on sinking pelagic detritus from the deep sea are as highly concentrated per unit dry weight of detritus as those from any shallow water or laboratory detritus[10–12]. Furthermore, ciliate concentrations on sinking particles remain high with depth, demonstrating that the decline in ciliate flux is due mostly to the decrease in the quantity of sinking material. The numbers of ciliates, their ultrastructural integrity in electron microscope sections, and their possession of food materials in vacuoles suggest participation in food webs to 2,000 m. The change in species composition with depth further supports the view that the ciliates are not passive members of the rich microbial communities but are populations actively responding to environmental alterations.

The numbers of ciliates relative to bacteria (Fig. 1*e*) indicate that decomposer communities of the aphotic zone have a population composition resembling that of other detrital communities and thus may be biologically regulated by mechanisms common to the others. In well-established detrital systems, substrate decomposition is largely due to bacteria but protozoa control the rates of mineralization by the bacteria by grazing on them. A variety of protozoa are usually present in detrital communities, but the largest of these—the ciliates—play pivotal roles in structuring the communities: they affect overall decomposition rates by consuming the abundant smaller protozoa that eat bacteria as well as by directly grazing the bacteria[10–12]. The deep-water ciliates we describe seem to belong to the decomposer assemblage on particulates because they contain bacteria, detritus, and other local food materials in their vacuoles, and no other significant ciliate food resources are available at these depths: the concentrations of cells in the water (as noted from water bottle samples) are several orders of magnitude less than on the sinking particles (unpublished results from this study and ref. 19). The abundance relationships between ciliates and bacteria further argue for the regulatory role of the former: communities with numerical ratios of bacteria/ciliates ranging from 10^2 to 10^4 represent detrital systems in which bacterial production is ultimately regulated and mineralization rates stimulated by the ciliates[10–12]. Since bacterial/ciliate ratios on sinking detritus from both euphotic and aphotic zones fall within this range, an equivalent functional role for the ciliated protozoa seems likely. Such a role does not negate the importance of other, smaller protozoans including microflagellates (which were also present but not counted in the present study), which may be the primary consumers of bacteria, but ciliates are probably the group that ultimately moderates the population sizes and activities of all the lower trophic level members of the decomposer community.

Because ciliates are so much larger than bacteria, the food base that supports the decomposer community, they are available to some consumers unable to capture bacteria. Ciliates may be significant trophic intermediaries between the prokaryotes, which are well known components of deep ocean food webs, and the metazoa. Our studies suggest that the ciliates could have that role on the particulates that rain into the deep sea.

Biological materials on sinking detritus are usually thought to originate from surface waters. However, the ciliates suggest more complex interactions among living components as the particles sink. The marked changes in species composition with depth indicate either a multiple-depth origin of the detritus, a colonization of the detritus at several depths by regional endemics, or a succession in which initially rare species progressively replace the early dominants. The high diversity of the protozoa, furthermore, indicates that the detritus represents a favourable growth environment and that ciliates occupy various niches in these densely populated micro-habitats. Thus the taxonomic data, as well as the biomass measurements, show that sinking particles support active, concentrated, and biologically regulated microbial communities passing through one of the most sparsely populated environments in the biosphere.

Vertical depth migrations, by the chambered cephalopod *Nautilus* when moving into shallower waters at night, were first documented by Wiley[1]. Although unsupported by quantitative data, this observation strongly influenced the interpretation of the mode of life of *Nautilus* and of the palaeoecology of fossil chambered cephalopods[2–4]. To determine whether these migrations do occur, we mounted ultrasonic transmitters on four *Nautilus belauensis* in Palau. The transmitters contained a strain-gauge depth sensor that caused the transmitters to emit sonic pulses at intervals that varied with depth, so that geographical position and depth could be ascertained. Our results indicate that at least in this population or geographical area, vertical depth changes of up to 200 m per day are common. Although too soon to make generalizations about other populations of *Nautilus* in the Pacific, it has been suggested that the morphological position of the siphuncle within the phragmocone of the chambered shell would increase the efficiency of vertical migrations in *Nautilus*, if such migrations were found to occur[5,6]. As similar siphuncle configurations are common in most post-Triassic nautiloids, and some ammonoids[6,7], it could be that vertical migration was common in many fossil forms as well.

The sonic transmitters were first calibrated in pressure tanks, and by submergence in the sea to known depths. The devices were designed to emit at different frequencies (between 38 and 41 kHz), allowing two *Nautilus* to be tracked simultaneously, and were filled with non-compressible glass microballoons to make the transmitters neutrally buoyant in seawater. The batteries gave the transmitters a life of 7–14 days, and a horizontal range of ~2 km. The transmitters sat in moulded rubber saddles that allowed them to be mounted on the tops of the shells of large, mature *Nautilus* (two males and two females). The *Nautilus* were captured at 200 m in baited traps, and after being fitted with the transmitters, immediately returned to the sea and released by divers at a depth of 70 m. All four *Nautilus* quickly descended to about 200 m, at which point the periods of observation were started. The *Nautilus* were tracked using Dukane hydrophones.

The four *Nautilus* monitored (termed Yellow, Green, Blue and Red, based on colour coding of the transmitters) were tracked for periods of between 2 and 10 days (Figs 1, 2) during June–July 1983. Completeness of tracking depended entirely on weather conditions. Conditions were nearly ideal during the tracking of Yellow, allowing continuous daytime and nighttime

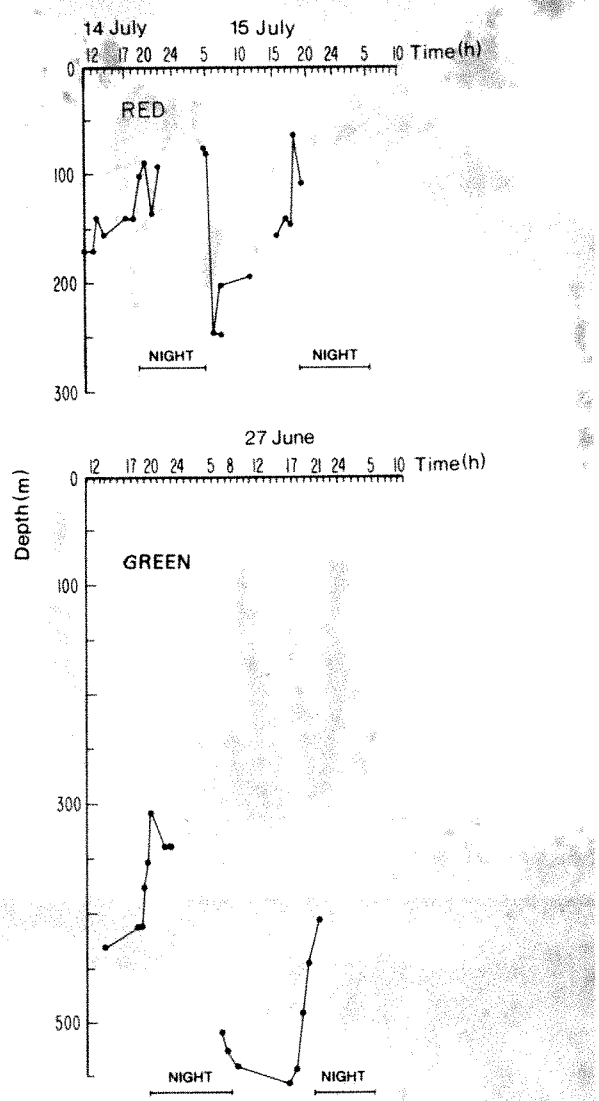

Fig. 1 Vertical movement of two *Nautilus*: Red, followed during 14–15 July 1983, and Green, followed during 27–28 June 1983.

work, but much less favourable for Green, Blue and Red, which were tracked mainly during daytime hours. All four animals showed significantly deeper mean daytime than nighttime depths (Table 1). Yellow, Red and Green showed daily ascents, occurring between 1600 and 2000, and descents between 0400 and 0700. (During our observation period (June–July 1983) sunset occurred at 1815 and sunrise at 0545.) Yellow was extremely regular in its diurnal movements. Blue was more irregular, and on three occasions (8, 10 and 13 October) showed evening descent rather than ascent. Because tracking was incomplete we do not know whether this animal ascended later on these evenings.

The tracking data indicate no daily rest periods. Although the largest scale depth displacements occurred at dawn and dusk, other vertical movements also occurred during day and night-time hours. We never observed any *Nautilus* spending longer than a few hours at the same depth; our data suggest nearly constant activity.

All four *Nautilus* showed substantial horizontal as well as vertical movement. One (Yellow) showed a somewhat regular pattern of movement around the south-west corner of Augulpelu Reef; each daylight period it moved into deeper water on the south side of the reef, while at night it moved around the point, into the large bay defined by Augulpelu and Ngadarak reefs, a distance of ~1 km. The other three *Nautilus* showed a different pattern. After being released near the point of Augulpelu reef, Green, Blue and Red began a daily southwestern movement along the 200 m contour of the bay. Superimposed

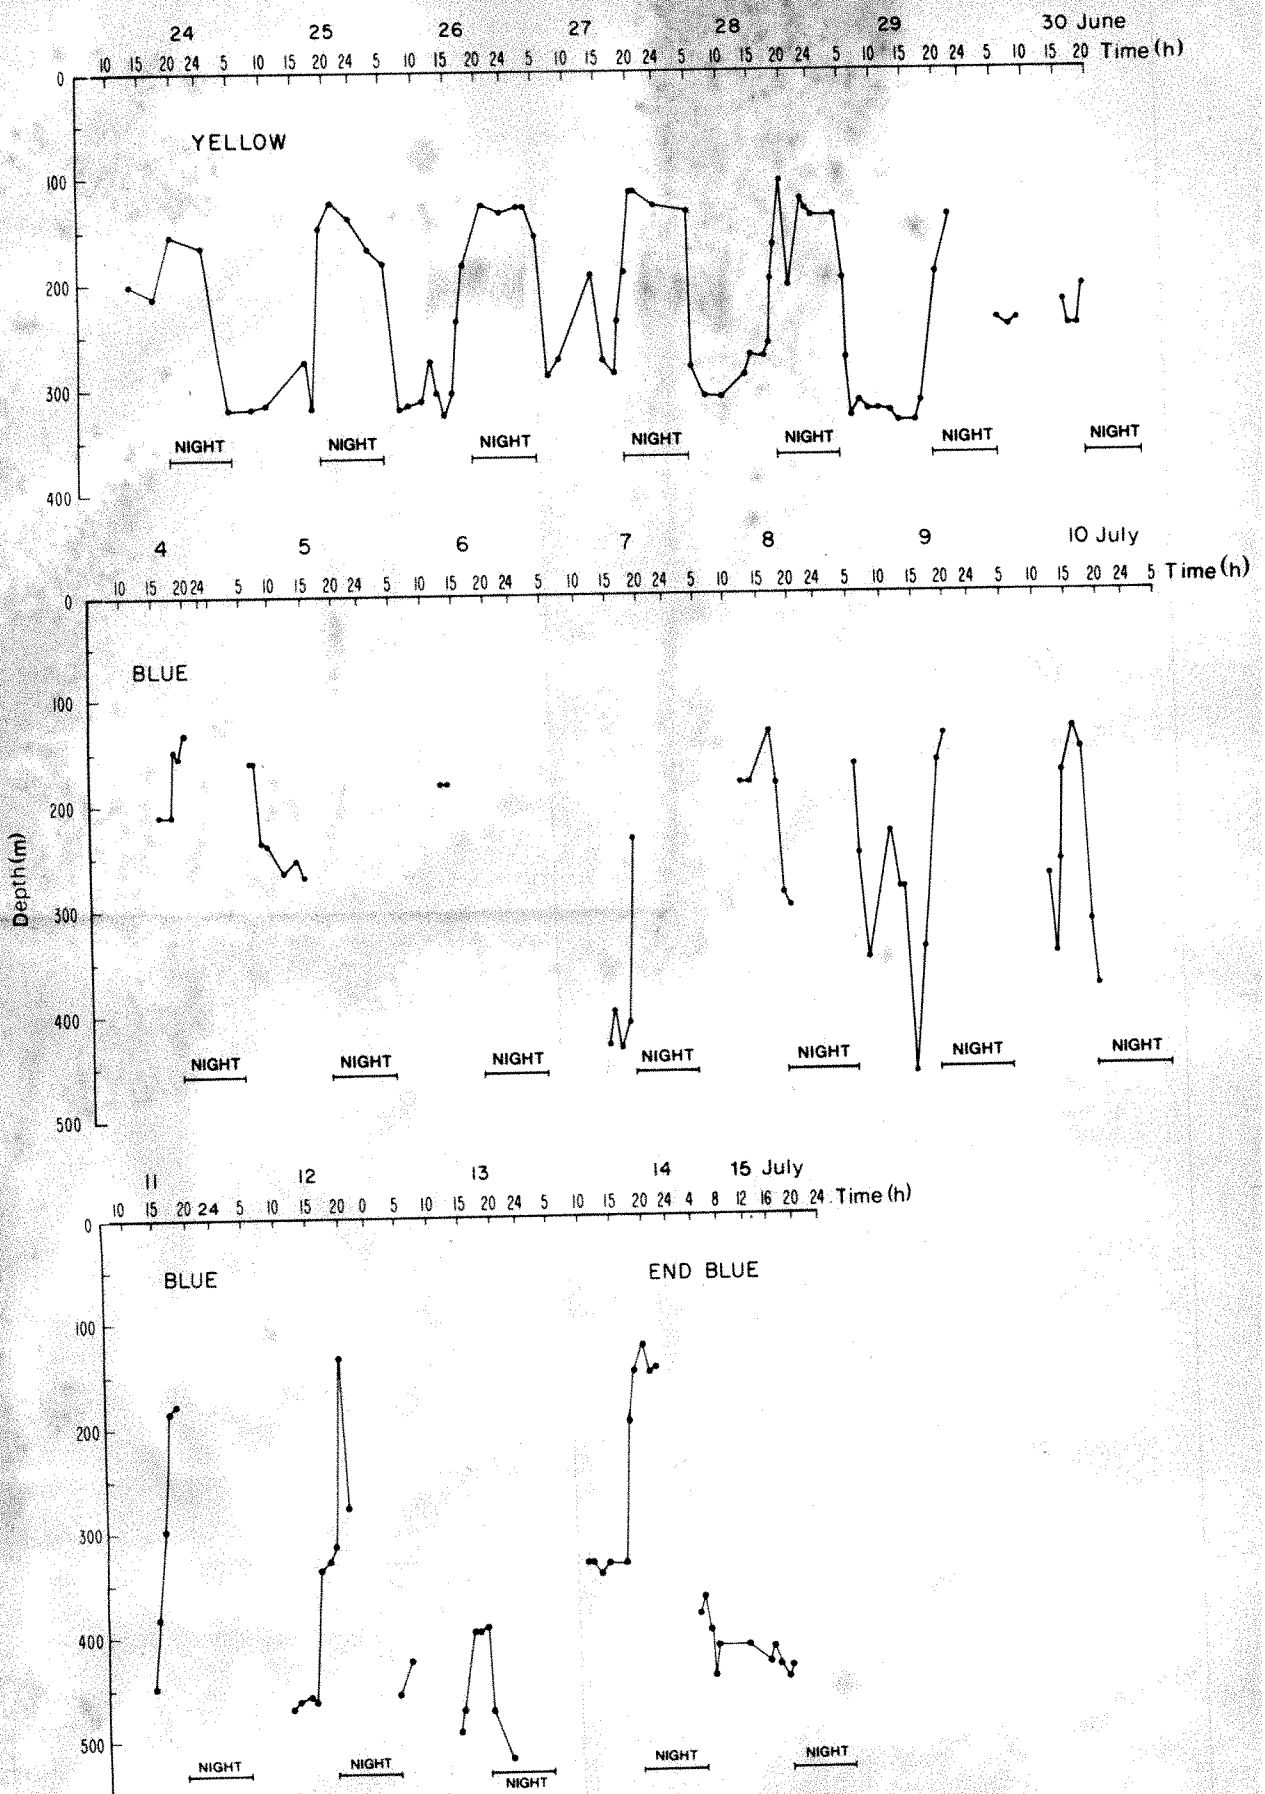

Fig. 2 Vertical movement with time of two *Nautilus belauensis*, Yellow and Blue. The ordinate records the depth, as derived from t strain-gauge depth sensor of the transmitter. Yellow was tracked from 24 to 30 June 1983. Blue was tracked between 4 and 14 July 198 Each dot represents the mean of 6–10 depth readings taken over a 2–3 min period. Numbers on the horizontal axes refer to the hour of da Periods of darkness (night) are indicated by bars at the bottom of each graph.

Table 1 Results of depth tracking for four specimens of *Nautilus*

Name	Sex	Dates of observation	Time*	Mean day depth† (m)	Mean night depth† (m)
Yellow	M	24–30 June 1983	152	290	153
Blue	F	4–15 July 1983	266	329	260
Green	M	26–27 June 1983	34	441	321
Red	F	7–15 July 1983	32	120	87

* Hours under observation.

† Derived from daytime and nighttime depth figures, with a maximum of two readings during any single hour being included. In the case of Yellow the mean depth figures were computed by integrating the depth curves.

on this southwestern horizontal movement was vertical movement, which was accomplished by inshore and offshore motion. Because of the steepness of the Palauan reefs, very short horizontal distances resulted in large vertical displacements. The Blue animal, followed for the longest period, travelled a total of 16 km along the reef front during the 10-day observation period. Horizontal movements of a similar magnitude have been observed previously for longer time periods in this population of *Nautilus*[8].

The depths at which *Nautilus* were found, as computed from the ultrasonic emissions, were compared with the bottom depth recorded nine times using a fathometer. The two depths differed significantly in only two cases, both involving the Blue transmitter. On 7 October 1983 Blue was followed for about 6 h as it ascended from 250 m depth to 150 m. At the end of this period the animal resettled to the bottom, after having travelled ~1 km horizontal distance. Although *Nautilus* appear to move mainly on the bottom, there does seem to be some movement within the water column.

We thank James McKibben for construction of the transmitters. This work was carried out at the Marine Mariculture Demonstration Center, Palau. Mr Tosh Paulis helped with boat acquisition. This work was supported by NSF grant PCM 8202891.

Gradual phyletic evolution at the generic level in early Eocene omomyid primates

Kenneth D. Rose

Department of Cell Biology and Anatomy, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, USA

Thomas M. Bown

Paleontology-Stratigraphy Branch, US Geological Survey, Denver, Colorado 80225, USA

Analysis of dental morphology in over 600 stratigraphically controlled specimens of tarsier-like primates from early Eocene strata in the Bighorn Basin, Wyoming, provides important new data for understanding the tempo and mode of evolution in primates. Here we describe two evolutionary transitions at the generic level in separate lineages of the family Omomyidae. In both lines transformation occurred not only continuously (rather than by abrupt appearance of new morphologies followed by stasis), but also in mosaic fashion, with greater variation in certain characters preceding a shift to another character state. In one lineage this resulted in a significant change in dental adaptation. These data support a gradual model of dental evolution and are inconsistent with the punctuated equilibria model. Together with other reported cases, the data suggest that gradualism is much more prevalent than proponents of punctuated equilibria have argued.

The early Eocene sequence of the Willwood Formation in the Bighorn Basin, Wyoming, is more than 700 m thick, spans about 4 Myr and is among the richest areas for fossil vertebrates in the world. Because of excellent stratigraphical control, samples from these deposits constitute some of the most important data for studies of mammalian evolution[1–12], including the largest and most diverse collection of omomyid primates known from any basin. This collection is now several times larger than the largest sample studied by previous workers, and nearly all specimens are tied into measured stratigraphical sections.

The omomyid samples have been assigned to at least six species in as many as six genera: *Teilhardina americana*, *Tetonoides tenuiculus*, *Tetonius homunculus*, *Pseudotetonius ambiguus*, *Absarokius abbotti* and *Omomys vespertinus*[7,13–20], and several undescribed species (Fig. 1). The systematics of these fossils is still under study, and it is clear that previous understanding of most of them was very incomplete. Our studies indicate that all of these species are valid, but it is debatable how many genera are represented. Here we provide evidence for the transitions between *Tetonius homunculus* and *Pseudotetonius ambiguus* and between *Teil. americana* and *Tetonoides tenuiculus*. Detailed justification will be provided elsewhere for recognition of *Teil. americana* and *P. ambiguus*, the validity of both of which has been questioned[20–22], but for this report, the taxonomy of the fossils is of less consequence than the evolutionary patterns they show.

All omomyids from the Bighorn Basin are conservative in molar morphology, differing consistently only in absolute size or relative breadth. Figure 1 shows that the molars separate to some extent on size alone. *Teilhardina* and *Tetonoides* are about the same size and are significantly smaller than *Tetonius* or *Pseudotetonius*, whereas the latter and *Omomys* are slightly smaller than *Tetonius*, and *Absarokius* is somewhat larger than *Tetonius*. Even so, the latter four taxa overlap substantially in molar size. To distinguish between them, differences in crown morphology, size and configuration of antemolar teeth are more important than molar size. Within each size group (Fig. 1), different morphologies are recognized under the specific names listed above, and our studies demonstrate that each comes from a restricted stratigraphical interval. Precise stratigraphical documentation has, therefore, been indispensable in determining relationships between species.

In the lineage from *Tetonius homunculus* to *P. ambiguus*, the anterior dentition evolved dramatically, while the molars and the last lower premolar (P_4) remained conservative. Here we apply the name *Tetonius homunculus* to the most primitive specimens (see also ref. 19), which have a relatively large, two-rooted P_3, a very small, one-rooted P_2, a moderate sized canine and second incisor (I_2), and an enlarged medial incisor (I_1). All such specimens (stage 1 in Fig. 2) are confined to the 180–190 m interval of the Willwood Formation in the principal study area (central and southern Bighorn Basin). *Tetonius* first appears at about 65 m but its anterior dentition is unknown below 180 m. Not all specimens in this lineage possess P_2; but from the stratigraphy it became clear that P_2 was lost after stage 1, beginning a trend toward progressive compaction and reduction of anterior teeth, except for I_1 which became larger with time. The name *Tetonius ambiguus* was first applied to a specimen showing extreme compression of the anterior dentition[17], but with increasing knowledge of variation in samples allocated to *Tetonius*, *Tetonius ambiguus* was transferred to a new genus, *Pseudotetonius*[14]. *P. ambiguus*, here shown to be the end point of the lineage, is characterized by a much reduced P_3 with one

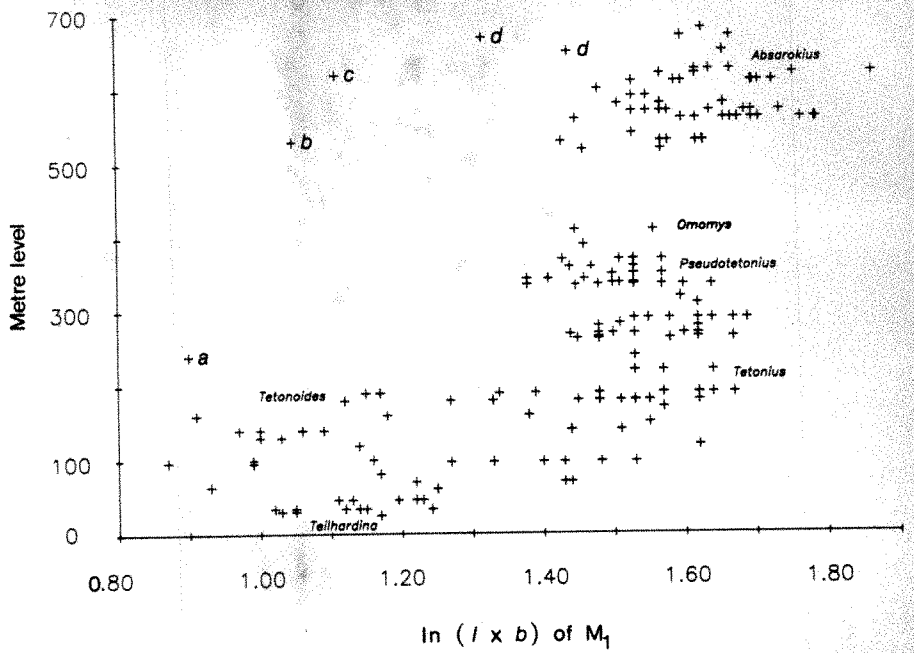

Fig. 1 Stratigraphical distributions of omomyid primates in the central and souther Bighorn Basin (Elk Creek, Fifteenmile Creek and Sand Creek sections). Abscissa show the natural logarithm of crown area (mm^2) of the first lower molar; the ordinate represents the stratigraphical level in Willwood Formation. Some points represent more than one individual. Names are placed near clusters of specimens that can be referred on morphological grounds to the species listed in the text and points situated stratigraphically between them represent evolutionary intermediates. Points *a–d* denote individuals belonging to undescribed taxa. Some taxa overlap considerably in size range of M_1, but their means may differ: for example, mean area of M_1 in *P. ambiguus* is less than in *Tetonius homunculus* and both are smaller than the mean for *A. abbotti*. Plots for other teeth show a similar pattern except that those based on P_3 and M_2 show greater separation between *Tetonius homunculus* and *P. ambiguus*, and that based on P_4 segregates *A. abbotti* more from other samples.

root or coalesced roots, absence of P_2, diminutive canine and I_2, and much enlarged I_1 (stages 4 and 5 in Fig. 2). The dentary anterior to P_4 is much shorter than in *Tetonius homunculus*. This morphology occurs in the 350–390 m interval in the study area, at the top of which *P. ambiguus* apparently became extinct (coinciding with an extinction–immigration event termed biohorizon B^{23}). Intervening strata have revealed morphologically intermediate specimens that record a gradual transition from *Tetonius homunculus* to *P. ambiguus* (Fig. 2).

Of particular interest is the mosaic pattern of change. Modifications that characterize *Pseudotetonius* did not appear synchronously, and certain characters (for example, P_3 root configuration) were more variable during periods of change. P_2 disappeared between stages 1 and 2; P_3 gradually diminished in size throughout the sequence while its two roots became closely appressed and merged into one from stages 2 to 5; the canine and I_2 became gradually smaller up-section; and I_1 enlarged, principally in stages 3 to 5. There was also a slight reduction in mean lengths of P_4 and the lower molars in stages 3–5. The sum of changes during this transition reflect an adaptive

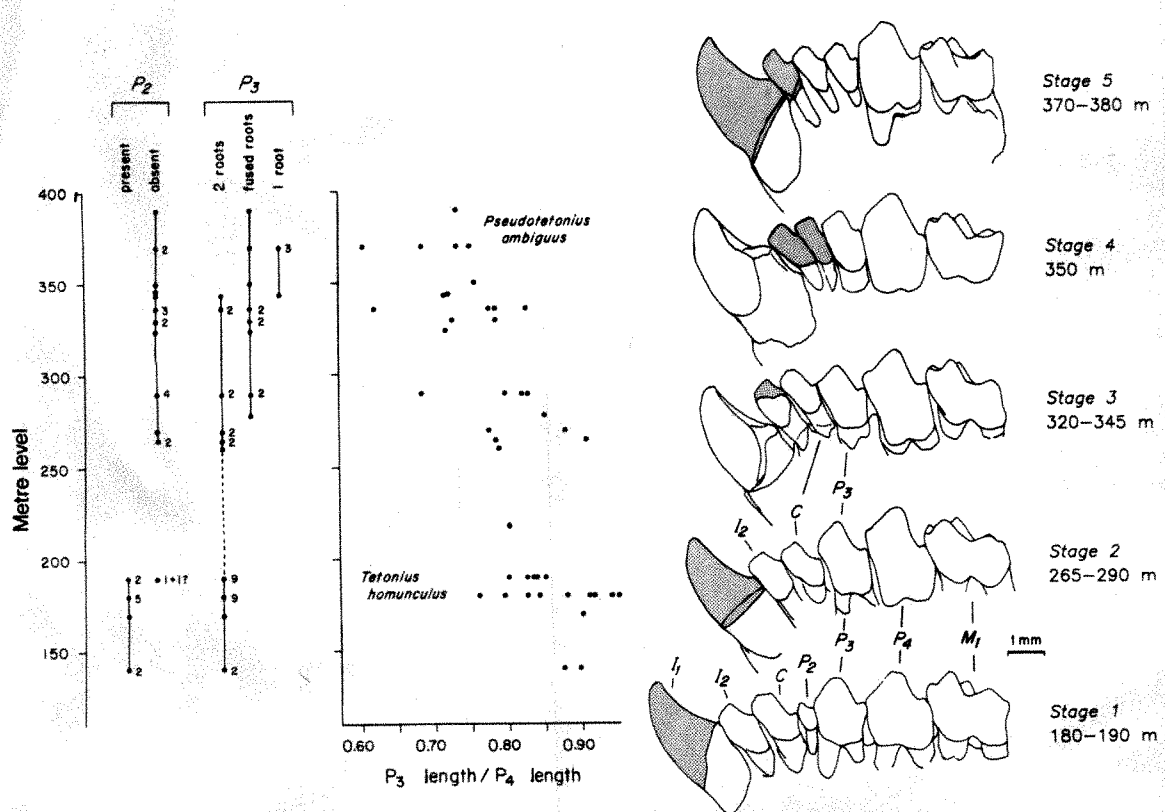

Fig. 2 Evolution of the anterior lower dentition in the *Tetonius homunculus–P. ambiguus* lineage from the central and southern Bighorn Basin. Stages in the transition are arbitrarily delimited by slight morphological differences and/or intervals with little or no data, and each is a composite dentition (M_{2-3} omitted) based on all known material from the indicated interval. Shaded parts are reconstructed from root size and known structure in other stages. The stratigraphical distribution of certain character states is shown on the left; numbers of individuals are indicated except where data points represent single specimens.

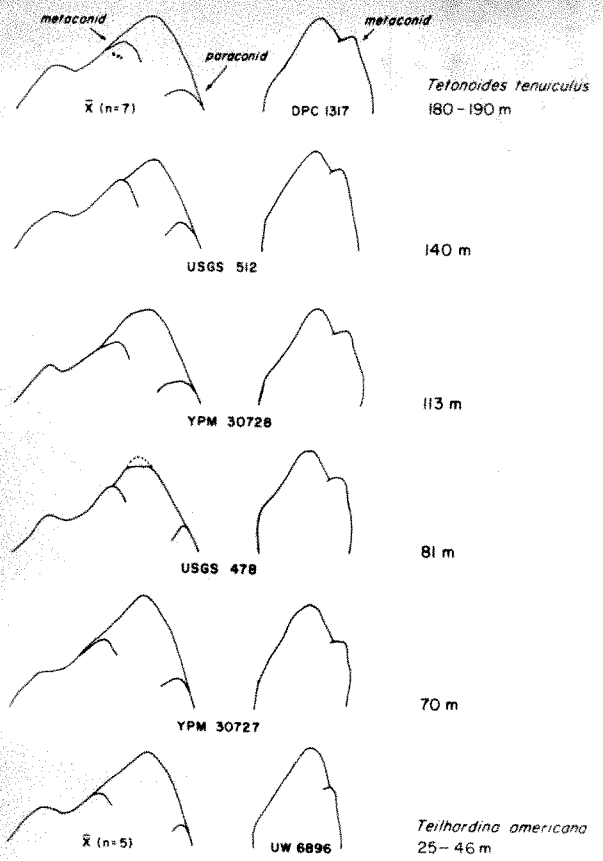

Fig. 3 Transformation of lower fourth premolar (P_4) in the *Teil. americana–Tetonoides tenuiculus* lineage. Left, computer-generated digitized lingual profiles, standardized to the same length so as to indicate only structural differences. Note the progressive enlargement and elevation of the metaconid and the elongation of the paraconid in successively higher strata. Right, camera lucida tracings, at constant magnification, of the back of the P_4 trigonid, showing the increase in size and height of the metaconid as well as increase in absolute breadth. Profiles for *Teil. americana* and *Tetonoides tenuiculus* are means computed from only complete, unworn specimens; other profiles depict individual specimens. Other known specimens from these levels conform to the morphologies shown.

shift to shorter-jawed omomyids with enhanced emphasis of the anterior grasping teeth and declining importance of the teeth just behind them.

Also found is a gradual transition from *Teil. americana* to *Tetonoides tenuiculus*, best documented in the morphology of the posterior lower premolars (P_{3-4}). *Teil. americana* is the oldest and most conservative North American omomyid[13,24] and, as in European *Teilhardina belgica* [clearly its congener (K.D.R., T.M.B. and M. Godinot, in preparation)], the P_3 and P_4 are relatively high-crowned, pointed and bear small, low conids, which are more pronounced on P_4; the cheek teeth are not basally inflated. These features occur only in the lowest 50 m (25–50 m interval) of the study area. *Tetonoides tenuiculus* differs from *Teilhardina* chiefly in having relatively broader and lower cheek teeth and a more molariform P_4, best illustrated by the higher, more salient paraconid and metaconid. Specimens in which this morphology is fully developed come from the 180–190 m interval in the study area. Fossils from intervening strata are intermediate between the two morphologies and become progressively more like *Tetonoides* up-section, the cheek teeth increasing in relative breadth and the paraconid and metaconid increasing in prominence with time (Fig. 3). At no level in the section is there an obvious morphological shift (punctuation); rather, change appears to be continuous and gradual. *Tetonoides tenuiculus* was short-lived in the Bighorn Basin (but a few stratigraphically higher specimens may be related to it: Fig. 1*a–c*), although the genus is known from younger rocks in other basins[25,26].

Both of the phyletic transitions described here are also recorded in samples from the Clark's Fork Basin, 100 km north of the study area. Those samples show the same sequence of changes in both lineages as observed in the study area, thus providing independent confirmation of the patterns reported here.

The tempo and mode of evolutionary change continue to be among the most actively debated issues in evolutionary biology, with particular attention currently focused on punctuational and gradual models of evolution[3,11,12,27–35]. The most convincing evidence for gradual evolution in fossil mammals has been advanced by Gingerich and colleagues[1–6], but these studies concentrate primarily on changes in molar size, and advocates of the punctuated equilibria model largely discount them[11,12]. The transitions in two lineages of omomyid primates detailed here involve a mosaic of continuously changing features that document the gradual evolution of new morphological types of generic rank. Together with Gingerich's examples and other detailed cases of gradual evolution[36–38], our data suggest that phyletic gradualism is not only more common than some would admit but also capable of producing significant adaptive modifications.

Retinitis pigmentosa (RP) is a group of retinal degenerations characterized by progressive visual field loss, night blindness and pigmentary retinopathy[1]. Its prevalence is in the region of 1–2 in 5,000 of the general population, making it one of the commoner causes of blindness in early and middle life[2,3]. Although 36–48% of RP patients are isolated cases, the remainder show autosomal dominant, autosomal recessive or X-linked modes of inheritance[4,5]. The X-linked variety (XLRP) is found in 14–22% of RP families in the UK[2,5]. In the present study, X chromosome-specific recombinant DNA probes which can detect restriction fragment length polymorphisms have been used to localize the XLRP gene(s) to a subregion of the X chromosome using linkage analysis. One of the probes, L1.28, has been shown to be closely linked to XLRP in five kindreds, with 95% confidence limits of 0–15 centimorgans (maximum LOD score of 7.89 at a distance of 3 centimorgans). This suggests that the XLRP locus lies on the proximal part of the short arm of the X chromosome. This probe is potentially useful for carrier detection and early diagnosis in about 40% of cases, provided that genetic heterogeneity can be excluded by analysis of further families.

XLRP is one of the most severe clinical forms of RP, with onset in males in the first decade, progressing to blindness by the third or fourth decade[6]. Female carriers show a variable but generally mild degree of visual loss, which occurs much later than in males and is associated with characteristically mild ophthalmoscopic changes in the retinal fundus and abnormalities on visual field, psychophysical and electrophysiological testing[7–9]. Partial manifestation in female carriers is generally attributed to random X-chromosome inactivation leading to unmodified expression of the XLRP allele in a proportion of retinal cells. Clinical and electrophysiological testing may detect only a proportion of carriers and then only at a relatively late stage of the disease. The loci for the Xg blood group and deutan colour blindness are not closely linked to XLRP and are therefore not useful in carrier detection[10,11]. Recently, restriction fragment length polymorphisms (RFLPs) have extended the utility of polymorphic markers in the detection of genes responsible for genetic disorders such as Huntington's chorea and Duchenne muscular dystrophy[12,13].

Families with XLRP were ascertained through ophthalmological genetic clinics in Edinburgh, Birmingham and London. The criteria used for diagnosis and establishment of X-linkage have been described previously[14]. Females at risk showing the ophthalmoscopic changes of carrier status, which were con-

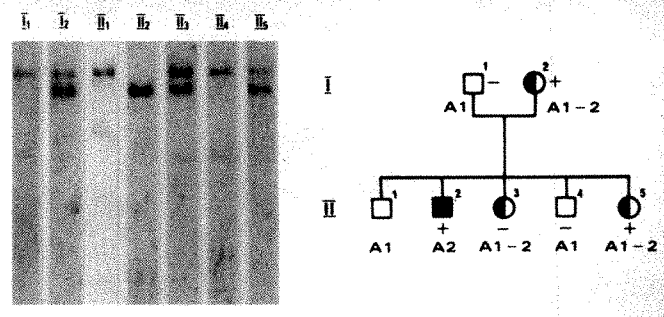

Fig. 1 The segregation of RFLP alleles identified with probe L1.28 in an XLRP family (F21). Carrier females (◐) are shown in generations I (I2) and II (II.3, 5). The mother (I.2) is an obligate heterozygote as she has a severely affected son (II.2, ■) and two carrier daughters. She is also heterozygous for the L1.28 polymorphism, showing the upper (12 kb) and lower (9 kb) bands. The unaffected sons (II.1, 4) have inherited allele A1 (12 kb) while the affected son has inherited allele A2 (9 kb) from the mother, as have the two carrier daughters. $Xg^a(+)$ and $Xg(-)$ blood group alleles are also shown.
Methods: DNA was prepared from 20 ml of whole blood or lymphoblastoid cell lines by the method of Kunkel *et al.*[22] and digested to completion using 5 units of *Taq*I per μg DNA for 20 min at 65 °C. The DNA digests (5 μg per track) were separated by overnight gel electrophoresis in 0.8% agarose, transferred to a nitrocellulose filter by the method of Southern[23] and hybridized for 18 h at 65 °C in 15 ml of 5 × SSC, 5 × Denhardt's solution, 0.1% SDS and 100 μg ml^{-1} denatured salmon sperm DNA. The L1.28 plasmid DNA was labelled by nick-translation with ^{32}P-dTTP (specific activity ~2×10^8 c.p.m. μg^{-1}), without excising the insert. The probe concentration in each filter hybridization was 10 ng ml^{-1} (3×10^7 c.p.m.). The filters were washed at room temperature in 2 × SSC for 20 min, followed by three washes of 20 min each in 0.1 × SSC, 0.1% SDS at 60 °C, then autoradiographed on Fuji film at −70 °C for 3–7 days using an intensifier screen.

Table 1 Analysis of linkage between XLRP, Xg and L1.28

Recombination fraction, Θ	XLRP −F15 $n=4$	L1.28 F15 alone $n=1$	XLRP +F15 $n=5$	Xg XLRP +F15 $n=8$
0.00	3.45	−∞	−∞	−∞
0.05	3.15	4.65	7.79	−6.81
0.10	2.82	4.45	7.27	−4.00
0.20	2.11	3.69	5.80	−1.65
0.30	1.33	2.69	4.02	−0.63
0.40	0.57	1.47	2.03	−0.16
Θ_{max}	0.00	0.04	0.03	0.50
LOD_{max} *	3.45	4.65	7.89	0.00
Θ_{mean}	0.08	0.10	0.06	0.47
Range (cM)	0–27	2–25	0–15	38–200
Odds (Θ < 0.3)	79:1	187:1	15,000:1	0.019:1
Odds (Θ < 0.2)	20:1	19:1	400:1	0.001:1

LOD scores are shown for different values of the recombination fraction (Θ) in XLRP families excluding F15 (−F15), including F15 (+F15) and in F15 alone. Maximum likelihood values of Θ (Θ_{max}) and the corresponding LOD scores (LOD_{max}) are shown together with the mean Θ values, the latter being a value more appropriate to genetic counselling[20]. A probability distribution for the recombination fraction was calculated from the likelihood curve (calculated at 51 values of Θ) and the linear prior probability for two unknown loci[21]. The Kosambi mapping function was used and the X chromosome was assumed to be 200 centimorgans long. The 95% confidence limits were estimated by excluding 2.5% of the area under the curve at each tail. The 'odds of linkage' were estimated by comparing the area under the curve at values of Θ less than 0.3 or 0.2 with that under the remainder of the curve. The number of informative kindreds is indicated (n).
* The LOD score is the $\log_{10}$ of the likelihood ratio, which is calculated by dividing the likelihood of observing the family data, for any value of Θ, by the likelihood if Θ is 0.5 (that is, random assortment or infinite separation of two loci).

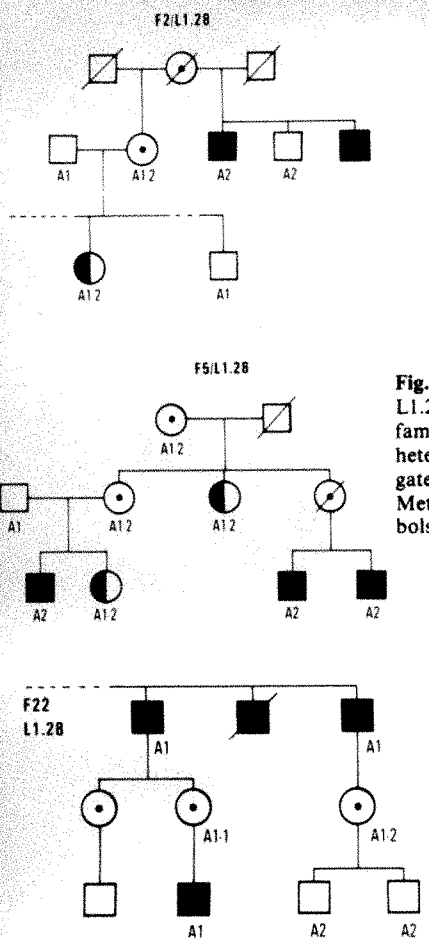

Fig. 2 Pedigrees and L1.28 alleles in XLRP families 2, 5 and 22. XLRP heterozygotes: ⊙, obligate; ◐, on testing. Methods and other symbols as described in Fig. 1 legend.

firmed by psychophysical and electrophysiological tests, were taken to be XLRP heterozygotes; otherwise the genetic status of females was not inferred unless the pedigree structure showed them to be obligate heterozygotes. Blood samples were obtained from 250 members of 24 XLRP families and lymphoblastoid cell lines were raised from obligate heterozygotes and individuals over 60 yr old.

Estimates of the genetic length of the X chromosome (150–250 centimorgans)[15] suggest that it should be possible to localize the XLRP gene with 10 suitably spaced X chromosome-specific recombinant DNA probes capable of identifying RFLPs. Three such probes assigned to the X chromosome short arm, each of which detects RFLPs with the same restriction endonuclease, *Taq*I, have been used so far; one of these, L1.28, was isolated from a human genomic library prepared from the placental DNA of a single individual by Pearson *et al.*[16]. The L1.28 probe is a single-copy X chromosome-specific DNA sequence, 1.25 kilobases (kb) long, that has been inserted in the *Eco*RI site of plasmid pBR322. It has been regionally assigned to Xp11.0-p11.3 by using somatic cell hybrids[16]. This probe identifies two RFLP alleles with the enzyme *Taq*I: A1, which is 12 kb long and A2, which is 9 kb long. These alleles occur at frequencies of 0.68 and 0.32 respectively in the Dutch population, on the basis of an analysis of 40 chromosomes. Digestion of DNAs from normal individuals using nine other restriction enzymes did not identify RFLP with L1.28 (ref. 16). In addition, 50 X chromosomes from 29 normal individuals have been analysed in Edinburgh and the frequencies of A1 and A2 were found to be 0.74 and 0.26. Overall, this suggests a heterozygote frequency of 0.41 (95% confidence limits 0.33–0.47).

Panels of DNA from XLRP obligate heterozygotes previously digested with *Taq*I were screened for RFLP heterozygosity using probe L1.28. Nine individuals, from five kindreds, were informative for the L1.28 polymorphism, out of a total of 28 obligate heterozygotes screened. The segregation of L1.28 alleles in one XLRP sibship is shown in Fig. 1. Linkage analysis was done using the computer program LIPED[17] and checked by hand.

In four of the kindreds, each with typical XLRP, there were no definite recombinants (Figs 1, 2) and the value of the recombination fraction (Θ), at which the likelihood is a maximum, is zero with a LOD score of 3.45 (Table 1). The fifth kindred (F15) was described by Hoare as having X-linked choroidoretinal dystrophy[18]. After review and subsequent examination, the consensus of opinion (G. W. Hoare, A.C.B. and B. S. Jay) is that the disorder in this kindred is within the clinical spectrum of XLRP. However, as the possibility of a second locus cannot be excluded, the scores for this kindred are presented both separately and together with the other kindreds (Table 1). Only one female in F15 (III.13), identified as a carrier on testing, was found to be a definite recombinant; the remainder were non-recombinant (Fig. 3). In F15, the maximum likelihood value of Θ is 0.04 at a LOD score of 4.65. The linkage data are therefore consistent with the F15 locus being identical with, or close to, that in the other kindreds. When the data from all the kindreds are combined, the maximum likelihood value of Θ is 0.03, corresponding to a distance of 3 centimorgans, at a LOD score of 7.89. The 95% confidence limits are 0–15 centimorgans and the odds of linkage at Θ values less than 0.3 are 15,000:1 (see Table 1).

Xg blood group data have been analysed in eight kindreds typed by Dr R. Sanger and Dr P. Tippett of the MRC Blood Group Unit, London (Table 1). Close linkage is excluded and

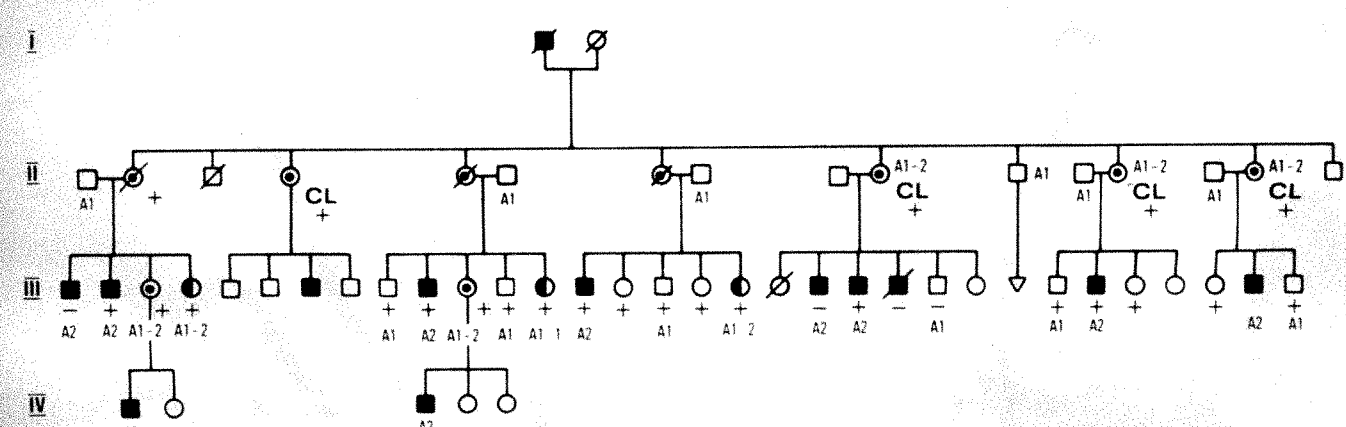

Fig. 3 F15 pedigree with L1.28 and Xg blood group results. This family is highly informative for the L1.28 polymorphism. All of the obligate heterozygotes available in generation II are also heterozygous for the RFLP and, with one exception, all XLRP hemizygotes (■) and heterozygotes (⊙, obligate; ◐, on testing) have inherited allele A2. The exception is III.13, who is homozygous for allele A1 and an XLRP carrier on testing; she is therefore a recombinant. L1.28 results of individuals whose XLRP status is uncertain have not been included in the pedigree. CL denotes that a lymphoblastoid cell line has been raised from that individual. $Xg^a(+)$ and $Xg(-)$ alleles are also shown. At least three recombinants between Xg and XLRP can be seen.

the 95% confidence limits for the genetic distance between the XLRP and Xg loci are 38–200 centimorgans. The Xg locus has been assigned to Xp22.3-pter[19] and the genetic length of the short arm of the X chromosome (Xp) is in the region of 60–90 centimorgans[15], so that the assignment of XLRP to within 15 centimorgans of L1.28 (assigned to Xp11.0-p11.3) is consistent with known distances on Xp. Recent evidence from somatic cell hybrids shows that the L1.28 locus is close to Xp11.3 (P.L.P. *et al.*, unpublished), so that while the precise relationship between physical and genetic maps in this region has yet to be established, it is likely that the XLRP locus is on the proximal part of Xp.

The finding of close genetic linkage between XLRP and the L1.28/*Taq*I polymorphism suggests that this could provide a useful means of carrier detection or prenatal diagnosis. However, more XLRP families informative for this RFLP must be examined to exclude significant genetic heterogeneity. Further work is also required to make more families informative for L1.28 and to map XLRP in relation to other neighbouring RFLPs.

S.S.B. was supported by the Sir Jules Thorn Charitable Trust and British Retinitis Pigmentosa Society. We thank Dr S. E. Bundey, S. J. Crews, G. W. Hoare, A. L. Lyness, M. P. Quinlan and A. G. R. Rennie for clinical information, access to patients and providing blood samples; Drs R. Sanger and P. Tippett for performing the Xg analyses; and Professor A. Laties and the National Retinitis Pigmentosa Foundation for encouragement and support.

Formation of germ-line chimaeras from embryo-derived teratocarcinoma cell lines

Allan Bradley*, Martin Evans*, Matthew H. Kaufman† & Elizabeth Robertson*

* Department of Genetics and † Department of Anatomy, University of Cambridge, Downing Street, Cambridge CB2 3EH, UK

The recent availability in culture of embryo-derived pluripotential cells which exhibit both a normal karyotype and a high differentiative ability[1–3] has encouraged us to assess the potential of these cells to form functional germ cells following their incorporation into chimaeric mice. We report here the results of blastocyst injection studies using three independently isolated XY embryo-derived cell lines (EK.CP1, EK.CC1.1 and EKCC1.2) which produce a very high proportion (>50%) of live-born animals that are overtly chimaeric. Seven chimaeric male mice, derived from these three lines, have, so far, proved to be functional germ-line chimaeras.

Although teratocarcinoma-derived embryonal carcinoma (EC) cells have been used to construct chimaeras, they have rarely realized the developmental potential demonstrated by embryonic inner cell mass cells used in a similar combination[4]. Indeed, when introduced into the early embryo many EC cell lines show a low rate of colonization and/or a restricted pattern of differentiation[5], and many chimaeras develop tumours both pre- and postnatally[4].

We have recently demonstrated that over 15 of our fertilized and parthenogenetically activated[6] embryo-derived (EK) cell lines of both XX and XY sex chromosome constitutions form normal chimaeras with high efficiency (in preparation). In this study we decided to use fertilized embryo-derived pluripotential XY cell lines, which, unlike most of their tumour-derived EC cell counterparts, readily differentiate *in vitro* and possess a normal euploid karyotype[3], an essential prerequisite for the formation of viable gametes. We now present data which clearly demonstrate that such cell lines are capable of forming functional germ-line chimaeras.

Table 1 gives the results of the blastocyst injection experiments and Table 2 the results of the test breeding studies. Figure 1 shows six of the phenotypically male chimaeras which transmitted functional spermatozoa derived from the introduced cells.

It would obviously be desirable to incorporate specific functional genes into the mouse genome. While direct transformation

Table 1 Rates of construction of chimaeras

Cell line	No. injected	No. born (%)	No. chimaeric (%)	Chimaeras Male	Chimaeras Female	Chimaeras ND	Males Set up	Males Bred	No. of germ-line chimaeras
EK.CP1	254	167 (66)	74 (44)	40	27	7	23	20	4
EK.CC1.1	69	52 (75)	31 (60)	21	10	0	13	8	1
EK.CC1.2	160	111 (70)	63 (57)	50	13	0	21	7	2
			Total:	111	50			35	7 (20%)

The EK.CP1, EK.CC1.1 and EK.CC1.2 cell lines were isolated from delayed blastocysts[1]. All of these lines are characterized by the possession of black and agouti coat colour markers. The EK.CP1 cell line was derived from a 129/Sv//Ev strain mouse and is homozygous for the *GPI-1*^{a} allele at the *GPI-1* (glucose phosphate isomerase-1) locus. EK.CC1.1 and EK.CC1.2 were derived from a substrain of 129/Sv//Ev which is homozygous for the *GPI-1*^{c} allele at the *GPI-1* locus. All three of these lines possess a normal euploid XY chromosome constitution and have been maintained entirely *in vitro* on feeder layers of inactivated fibroblasts. The breeding data available for some males are incomplete; these might yet prove to have a low-level culture-derived germ-line component. There is a very evident distortion of the sex ratio in the live-born chimaeras—this deviation in favour of males is highly significant (χ^2, $P < 0.001$) and probably reflects the conversion of a number of 'host' female embryos to male chimaeras. ND, not determined.

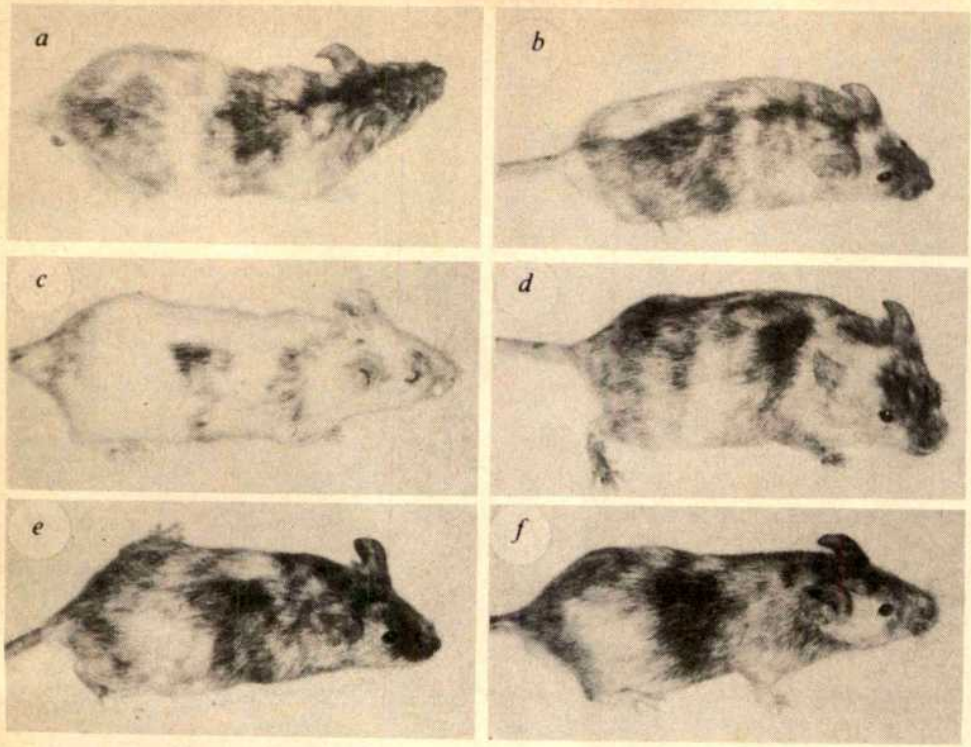

Fig. 1 Six of the seven germ-line chimaeras described in Tables 1 and 2. *a*, CP1.3; *b*, CP1.5; *c*, CP1.11; *d*, CC1.1.3; *e*, CC1.2.6; *f*, CC1.2.8. Between 8 and 12 embryo-derived cells were introduced into the blastocoelic cavity of host-fertilized blastocysts homozygous for the recessive albino locus. The blastocysts were then allowed to re-expand and were subsequently transferred to the uterine lumen of recipients on the third day of pseudopregnancy. All the conceptuses were allowed to develop to term, and live-born animals were scored for the presence of eye and coat pigmentation at or shortly after birth.

of the zygote has recently shown much promise[7–13], an alternative approach is the construction of individuals between 'modified' pluripotential cells and normal embryos. This second approach has the advantage that cultured cells are accessible for genetic manipulation, characterization and selection before their incorporation *in vivo*. Several EC cell lines have been selected *in vitro* to carry specific mutations or additional intact 'foreign' chromosomes, and have subsequently been incorporated into chimaeric individuals[14–17]. It is, however, a necessary prerequisite to demonstrate that germ-line chimaerism can be reliably achieved. Published rates of construction of germ-line chimaeras using EC cell lines have been disappointingly poor[18,19]. There has been a report of a single XX cell line, maintained completely *in vitro*, from which two germ-line females have been obtained. In addition to a low rate of chimaera formation (13%), these females produced only four progeny having an EC-derived component[20,21].

Table 2 Breeding data from the seven functional germ-line chimaeras

Male chimaera	No. of litters	No. of offspring	No. albino	No. black agouti
CP1.3	10	78	0	78
CP1.5	16	170	163	7
CP1.11	2	23	22	1
CP1.34	1	5	0	5
CC1.1.3	1	12	0	12
CC1.2.6	1	13	0	13
CC1.2.8	1	11	0	11

Phenotypically male chimaeras were caged with successive virgin CFLP females homozygous for the *GPI-1*^{b} allele and the albino locus. Resulting litters were scored for the dominant black and agouti phenotypes. GPI analysis of blood samples taken from all the black agouti offspring has shown the predicted *GPI-1*^{a}*1*^{b} (EK.CP1) or *GPI-1*^{b}*1*^{c} (EK.CC1.1 and EK.CC1.2) genotype, thus verifying the inheritance of these culture-maintained lines. The chimaeras which appear to be breeding from their XY culture-derived component alone are probably sexual mosaics, although phenotypically they are normal males, as any XX germ cells would not be capable of forming functional spermatozoa.

Clearly, embryo-derived stem cells seem to be particularly efficient at recolonizing the early embryo. This feature, together with the availability of XY lines such as those described here, now allows the routine construction of chimaeric males which are capable of transmitting culture-derived genomes to a potentially limitless number of offspring, and confirms our previous contention of the normality of the genome in these stem cell lines[22].

We thank Pam Fletcher for technical assistance. This work was supported by grants from the MRC (M.E. and M.H.K.) and the Cancer Research Campaign (M.E.). A.B. is supported by a MRC Studentship. The EK.CP1 cell line was isolated by Marie-Therese Schnebelen of the College de France, Paris, while in Cambridge on an EMBO short-term fellowship.

Note added in proof: A further four males described in Table 1 have proved to be germ-line chimaeras (three from the CC1.2 and one from the CC1.1 cell lines).

Spinal opiates affect sexual behaviour in rats

Z. Wiesenfeld-Hallin* & P. Södersten†

Departments of * Clinical Neurophysiology and † Psychiatry, Karolinska Institutet, S-141 86 Huddinge, Sweden

Enkephalin-containing cells in the substantia gelatinosa of the spinal cord[1] participate in the neural processing of painful stimuli[2,3]. Spinal opiates may also be involved in the perception of sensory stimuli related to reproduction, as probing of the uterine cervix stimulates sexual behaviour in rats[4] and also induces an analgesia[5] which is partially dependent on opiate receptor mechanisms in the spinal cord[6–8]. We now report that the intrathecal injection of morphine into female ovariectomized rats pretreated with oestradiol benzoate and progesterone inhibits sexual receptivity while injection of the opiate receptor antagonist naloxone enhances it. Similarly, intrathecal injection of morphine increases while injection of naloxone decreases the number of intromissions before ejaculation in male rat. Intraperitoneal injection of morphine or naloxone has no behavioural effect. Recent studies have suggested that brain opiates are involved in the control of sexual behaviour[9–11]. The results reported here indicate that sexual behaviour may also be influenced by spinal opiates.

Female Wistar rats (200–220 g) were ovariectomized and 1 week later a polyethylene catheter was inserted into the subarachnoidal space of the lumbosacral spinal cord as described elsewhere[12]. One week later the rats were injected with oestradiol benzoate and progesterone and tested individually with male rats. All females showed lordosis (concave back flexion, lateral tail deviation and neck extension) to all mounts and were thereafter divided into four groups and injected intrathecally (i.t.) with the opiate receptor agonist morphine in doses which produce moderate analgesia but do not disturb motor function[13,14]. The number of lordosis responses to 10 mounts by the male was recorded 15 and 60 min after the morphine injection and a lordosis quotient was calculated as: (number of lordosis responses) × 10.

Fourteen ovariectomized rats, pretreated with oestradiol and progesterone, were divided into three groups and injected intraperitoneally (i.p.) or i.t. with morphine. One group given morphine i.t. was injected i.p. with the opiate receptor antagonist naloxone and the other group received an i.p. injection of NaCl. The rats were tested with males 60 min after the morphine injection and lordosis quotients were calculated when the males had mounted 10 times.

Sixteen ovariectomized rats, which showed an overall mean ± s.e.m. lordosis quotient of 43.6 ± 10.5 after pretreatment with a low dose of oestradiol and progesterone were divided into three groups and injected with naloxone i.t., in doses which produce moderate hyperalgesia[15,16], or i.p., or with NaCl i.t. The rats were tested with males 10 min after the naloxone injection.

Sexually experienced Wistar male rats (300–350 g) were implanted with i.t. catheters and tested 1 week later for sexual behaviour. A sexually receptive female was introduced to each male and the number of mounts with and without intromission and the latency to the first intromission, the interval between the first intromission and ejaculation and the interval between ejaculation and the next intromission were recorded. Two days later the rats were divided into four groups and injected i.t. with NaCl, naloxone, morphine or morphine + naloxone i.p. and tested for sexual behaviour according to the same time schedule as used with the females. Three other groups of males were injected i.p. with NaCl, naloxone or morphine and tested for sexual behaviour as above.

Figure 1*a* shows that i.t. injection of morphine suppressed sexual receptivity over time. Between-group comparisons showed that morphine caused a dose-dependent inhibition of lordosis both 15 and 60 min after i.t. injection. As little as 1 μg

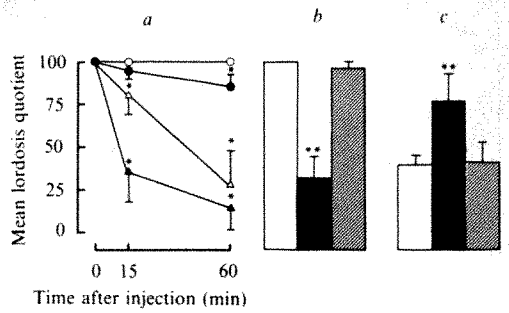

Fig. 1 *a*, Effect of intrathecal (i.t.) injection of 0 (○), 1 (●), 5 (△) or 10 (▲) μg of morphine on sexual receptivity (mean ± s.e.m. lordosis quotient) induced by 10 μg oestradiol benzoate (48 h) and 0.5 mg progesterone (6 h) before the morphine injection. *b*, Effect of intraperitoneal (i.p., open bar) or i.t. (black bar) injection of 5 μg morphine 60 min before testing and of i.t. injection of 5 μg morphine 60 min before testing in combination with 400 μg naloxone i.p. (cross-hatched bar) given 10 min before testing on sexual receptivity induced as in *a*. *c*, Effect of i.p. (open bar) or i.t. (black bar) injection of 50 μg naloxone or 0.9% NaCl i.t. (cross-hatched bar) given 10 min before testing on sexual receptivity induced by 0.8 μg oestradiol (48 h) and 0.5 mg progesterone (6 h) before the naloxone injection. Oestradiol and progesterone (Sigma) were dissolved in 0.1 ml sesame oil and injected subcutaneously. Morphine chloride (Apoteksbolaget) was dissolved in 10 μl 0.9% NaCl and injected i.t. through a Clay Adams PE10 polyethylene catheter or in 0.5 ml NaCl i.p. The i.t. catheter was flushed with 10 μl NaCl after the injection. Naloxone hydrochloride (Endo Laboratories) was dissolved and injected as the morphine. * Significantly different from NaCl-injected controls or ** i.p. morphine-injected (*b*) or i.p. naloxone-injected (*c*) rats; *P* at least <0.05 Mann–Whitney *U*-test after one-way analysis of variance. There were four to six rats per group.

morphine significantly inhibited lordosis behaviour 60 min after injection. Rats given an i.t. injection of morphine showed significantly lower lordosis quotients than rats given morphine i.p., while i.p. injection of naloxone reversed the effect of the i.t. morphine injection (Fig. 1*b*). Figure 1*c* shows that an i.t., but not i.p., injection of naloxone facilitated sexual receptivity in rats given a low dose of oestradiol and progesterone.

Males given naloxone i.t. showed fewer and males given morphine i.t. showed more intromissions before ejaculation than males treated with NaCl i.t. (Fig. 2*a*). The effect of morphine was reversed by an i.p. injection of naloxone (Fig. 2*a*). None of the other parameters of sexual behaviour was changed by the i.t. injections (data not shown). Intraperitoneal injections of either naloxone or morphine had no effect on intromission frequency (Fig. 2*b*).

In the female rat, spinal segments L1 to S1 are important for processing sensory stimuli provided by the male during copulation[17]. Denervation of peripheral skin[18] or transection of the spinal cord at levels receiving cutaneous information during copulation[19] reduces the intensity of sexual behaviour in female rats. Injection of morphine in the subarachnoidal space surrounding these spinal segments produced a dose-dependent inhibition of sexual receptivity in female rats in our study, and this effect was reversed by naloxone. Also, an i.t. naloxone injection facilitated the behaviour of female rats made partially receptive by injection of low doses of ovarian hormones. Since no behavioural effects were noted when either morphine or naloxone was administered at a site distant from the spinal cord, we suggest that one function of dorsal horn opiates in female rats is to modulate sensory stimulation provided by the male during copulation. Thus, stimulation of the uterine cervix of female rats occurs naturally during sexual interactions in the rat[20] and it is tempting to speculate that the ensuing analgesia, which is partially opiate dependent[5], may reflect a copulation-induced release of enkephalins in the dorsal horns of the spinal cord. This, in turn, may underlie such a physiologically relevant phenomenon as copulation-induced inhibition of behavioural oestrus in the female rat[21].

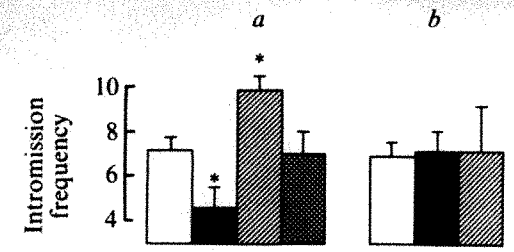

Fig. 2 Effect of intrathecal (*a*) and intraperitoneal (*b*) injection of 0.9% NaCl (open bars), 50 μg naloxone (black bars), 5 μg morphine (cross-hatched bars) or 5 μg morphine in combination with 400 μg naloxone i.p. (stippled bar) on intromission frequency (mean ± s.e.m. number of intromissions before ejaculation) in male rats tested with sexually receptive female rats. Naloxone was given 10 min and morphine was given 60 min before testing. * Significantly different from NaCl-injected controls; $P < 0.05$ Mann–Whitney *U*-test after one-way analysis of variance. There were four or five rats per group.

During copulation, male rats show multiple intromissions, which serve to facilitate ejaculation[22]. Anaesthesia of the penis[23] or section of the dorsal penile nerve[24] prevents the display of intromission and ejaculation. Thus, sensory stimulation of the penis is required for normal copulation in male rats. It seems likely that spinal opiates may serve a function in coding the sensory information value of each intromission as an i.t. naloxone injection decreased the number of intromissions shown by males before ejaculation and an i.t. morphine injection produced a naloxone-reversible increase in intromission frequency. Naloxone or morphine injections had no behavioural effects if given i.p. Sensory information from the penis is carried by the dorsal penile nerve, the cell bodies of which are located in dorsal root ganglion L6[25]. These cells have extensive collateral projections to segments T12–S3 in the substantia gelatinosa of the spinal cord[25], that is, the segments around which the i.t. injections were made in our study.

Recent work on the physiological role of spinal opiates have concentrated exclusively on their involvement in the perception of pain[1,2]. The present results suggest that enkephalins in the spinal cord may participate in the coding of a broader range of sensory information.

This work was supported by the Swedish MRC (5318), the Swedish Council for Research in the Humanities and Social Sciences (F224/83) and the Funds of the Karolinska Institute. We thank Apoteksbolaget for supplying morphine and Endo Laboratories for naloxone.

Vasopressin was among the first mammalian hormonal peptides to be identified and to have its structure determined[1]. Its only undisputed physiological role is as a circulating neurohypophyseal antidiuretic hormone. Other notable effects of vasopressin on peripheral tissues include contraction of vascular smooth muscle, leading to elevation of blood pressure, and activation of glycogenolysis in liver. It has long been clear that vascular smooth muscle and hepatocytes are relatively insensitive to the low concentrations of vasopressin normally present in the circulation, and the physiological significance of their responses has therefore been in doubt. We now report that a new bioactive and immunoreactive vasopressin-like peptide (VLP) is widely distributed in the sympathetic nervous system of mammals, both in the principal noradrenergic neurones of ganglia and in nerve fibres innervating peripheral tissues. In addition to other peptides described in the mammalian sympathetic nervous system[2], VLP must be considered as a possible mediator of the non-adrenergic responses to sympathetic activation. Moreover, many of the effects previously attributed to circulating vasopressin may be neurally evoked.

Using several antisera having high specificity for arginine-vasopressin (AVP, Table 1 legend), significant quantities of VLP were detected in rat superior cervical and coeliac ganglia (Table 1). The levels detected in the coeliac ganglia were one-quarter those found in the superior cervical ganglia, suggesting that there may be some rostral–caudal differences in the levels of VLP along the sympathetic chain, as has been found for vasoactive intestinal polypeptide (VIP)[3]. Detectable levels of oxytocin-like immunoreactivity were also found by using an oxytocin-specific radioimmunoassay, but the levels were about one-tenth those found for VLP (Table 1). The apparent VLP levels in rat superior cervical ganglia are comparable to the levels of substance P-like immunoreactivity expressed after explant culture of the ganglia[4].

The Brattleboro rat, a mutant of the Long–Evans strain, lacks AVP and consequently proved an important tool in vasopressin research[5]. Specific radioimmunoassays demonstrated that the superior cervical ganglia of Brattleboro rats had significant levels of both vasopressin-like and oxytocin-like immunoreactivity, although the levels of the former were 40% of those measured in Long–Evans controls (Table 1).

Gel filtration established that VLP migrates as a single immunoreactive peak with a higher apparent molecular weight than authentic vasopressin (Fig. 1). Because VLP was extracted from pooled ganglia for gel filtration experiments, it should be considered that the material present at nerve endings may be a processing product of VLP detected in ganglia. The oxytocin-like immunoreactivity co-migrated with VLP, suggesting that the oxytocin and vasopressin antisera recognized a common peptide. Ganglion extracts contained no authentic AVP on analysis by HPLC.

The cross-reactivity of VLP with some, but not all, AVP and oxytocin antisera permitted an investigation of its distribution

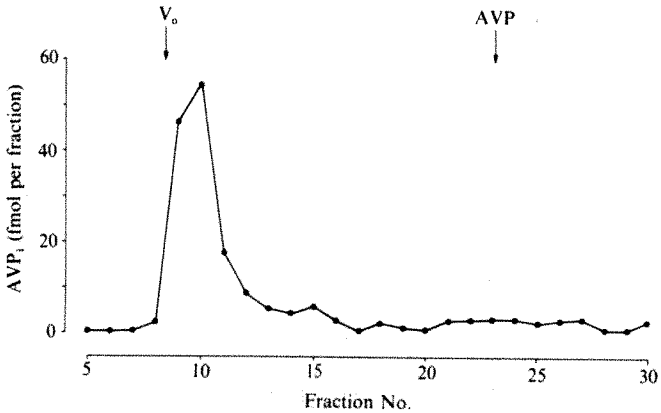

Fig. 1 Elution profile of arginine-vasopressin immunoreactivity from extracts of rat superior cervical ganglia on Sephadex G-25. Extracts were prepared by homogenizing pooled, frozen ganglia from 10 Sprague–Dawley rats in 0.5 ml 50 mM HCl with an ultrasonic disintigrator (MSE Soniprep 150). The homogenate was extracted through acidified octadecasilylsilica columns (Table 1 legend) and resuspended in 1 ml 0.1 M Tris-HCl buffer (*p*H 7.4). This extract was applied to a 1.0×30 cm Sephadex G-25 (fine) column equilibrated in the same buffer. The column was run in this buffer at 45 ml per h at room temperature and 1-ml samples were collected. Aliquots were assayed for arginine-vasopressin immunoreactivity by the technique described in Table 1 legend. Recovery was 70% of that in the applied sample. The void volume (V_0) and the elution position of authentic arginine-vasopressin (AVP) are indicated by arrows. Aliquots were also assayed for oxytocin immunoreactivity, which co-migrated with the AVP-immunoreactivity (AVP_I).

Table 1 Levels of vasopressin- and oxytocin-like immunoreactivity in rat sympathetic ganglia, and comparison with published concentrations of some other immunoreactive neuropeptides in rat sympathetic ganglia

Immunoreactive peptide	Superior cervical ganglion (fmol per ganglion) Normal Long–Evans rat	Superior cervical ganglion (fmol per ganglion) Brattleboro rat	Coeliac ganglion (fmol per ganglion) Normal Long–Evans rat
Vasopressin-like	211 ± 26.5* (12)	85 ± 11.5* (12)	58.2 ± 8.8* (8)
Oxytocin-like	23 ± 0.8* (14)	25 ± 1.6* (13)	ND
	Normal Sprague–Dawley rat		Normal Sprague–Dawley rat
Substance P-like	30–40 (ref. 15)		270 ± 30 (ref.15) 180 ± 40 (ref. 16)
Bombesin-like	ND		3,900 ± 800 (ref. 16)

* Although the recorded concentrations of vasopressin- and oxytocin-like immunoreactivity are based on standards of arginine-vasopressin and oxytocin, the peptide present in ganglia is neither of these (see the text and Fig. 1) and these assays are therefore likely to underestimate the true concentration of ganglionic VLP. The values given are means ± s.e.m. (number of ganglia analysed). ND, not determined. Rats were anaesthetized with sodium pentobarbitone (72 mg per kg) and the superior cervical and coeliac ganglia were dissected and frozen. Each ganglion was then suspended in 0.5 ml 50 mM HCl, homogenized using an ultrasonic homogenizer (MSE Soniprep 150), and centrifuged for 5 min at 11,600*g*. The supernatant was decanted and neutralized with an equal volume of 0.1 M Tris HCl + 10 μl 1 M NaOH. A 0.1-ml aliquot of the neutralized homogenate was added to 1 ml 0.1 M HCO_2H, and passed through an acidified octadecasilylsilica column (C_{18} Sep-Pak; Waters Associates). The column was washed with 3 ml 0.1 M HCO_2H and eluted with 3 ml 95% methanol/5% 0.1 M HCO_2H. The eluate was dried *in vacuo*, resuspended in 0.5 ml assay buffer, and assayed in duplicate by a modification of the technique of Lightman and Forsling[17] at three serial dilutions. In brief, ~4,000 c.p.m. of ^{125}I-arginine-vasopressin tracer (NEN, 1,820 Ci per g) was added and samples were incubated for 48 h at 4 °C. Free and bound tracer were separated by ethanol precipitation, and the bound fraction was counted by a γ-counter. The anti-vasopressin antiserum used here was kindly provided by Stefan Lundin (Ferring Pharmaceuticals). Its cross-reactivity with oxytocin is 0.1%, with lysine-vasopressin 10%, and with desamino-D-arginine vasopressin 0.01%.

by immunocytochemical techniques. Using immunofluorescence, superior cervical, coeliac and thoracic ganglia from two mammalian species (rat, macaque monkey) revealed staining of large neurones in the ganglia (Fig. 2). Because it seemed likely that this staining was restricted to noradrenergic principal neurones, sections of superior cervical ganglia were stained first for VLP and subsequently for dopamine-β-hydroxylase (DBH). All VLP-positive neurones were also stained by anti-DBH, although it is not clear whether all DBH-positive neurones are VLP-positive. It is clear, however, that this pattern is not specific to any particular ganglion or species; it appears to be widespread in the sympathetic nervous system. In some sections, a plexus of nerve fibres could be detected (Fig. 2*c*) surrounding the large neurones. Because the plexus stains for both VLP and DBH, it seems likely that it arises from postganglionic neurones, although its precise anatomical origin is unknown.

Sympathetically innervated tissues were examined for peripheral fibres that might correspond to the projections of the VLP-positive neurones. In liver and kidney, two known targets of vasopressin, numerous immunoreactive fibres were detected. In the hilar region of the liver, VLP-positive nerve fibres were found running in the smooth muscle layers of the hepatic blood vessels (Fig. 3*b*), but none was found in apposition to the bile ducts. Similarly, blood vessels of the kidney, particularly the renal artery (Fig. 3*a*), showed a high density of immunoreactive fibres. In the kidney, fibres were also found in a variety of other structures, for example, in the vicinity of collecting ducts. This is of considerable interest, as vasopressin exerts more than one action on the kidney. A detailed investigation of the renal VLP-positive fibres at both the light and electron microscope level may reveal unexpected possibilities for direct neural control. Similar VLP-positive fibres have been observed in other sympathetically innervated peripheral organs, such as rat submandibular gland.

Because activation of V_1 vasopressin receptors in liver and artery stimulates inositol lipid breakdown[6], we examined inositol lipid metabolism in rat sympathetic ganglia in order to detect functional V_1 receptors. Rat superior cervical ganglia were stimulated with AVP after incubation with ^{3}H-inositol, and the production of inositol phosphates from inositol lipids was measured[7]. The response was rapid, with detectable accumulation of inositol bis- and trisphosphates within 15 s (Table 2*a*), suggesting primary breakdown of phosphatidylinositol 4,5-bisphosphate, as in liver[8]. Stimulated inositol lipid breakdown is also a response of these ganglia to muscarinic cholinergic stimulation, but the response to AVP is several times larger[9]. The half-maximal response to AVP occurred at ~30 nM AVP[9], and was blocked by a specific V_1-receptor antagonist (Table 2*b*). The AVP-stimulated accumulation of inositol phosphates was unaffected by a reduction in extracellular Ca^{2+} concentration, suggesting that it is a primary receptor-coupled event rather than a secondary response to another mediator released from AVP-sensitive neurones. Ganglia showed little or no change in cyclic AMP content when exposed to AVP, indicating that they possess few, if any, functional V_2 receptors. The matching of the biochemical responses in ganglia with those in sympathetic target tissues suggests that this is a coordinated system in which VLP may be the preferred endogenous stimulant of V_1 responses.

To test the biological actions of VLP, a sympathetic ganglion extract was freed of catecholamines by adsorption to a miniature reverse-phase column. When injected intravenously into alcohol-anaesthetized, water-loaded rats, the extract had a marked antidiuretic effect with no effect on blood pressure. Thus, although VLP shares at least one biological action with AVP, the relative potencies at V_1 and V_2 receptors cannot yet be assessed.

The simplest interpretation of the data is that VLP is a novel neuropeptide in postganglionic sympathetic neurones that contain and secrete noradrenaline. In this regard, it is important to establish the relationships between VLP and other neuropeptides detected in mammalian sympathetic ganglia. Only neuropeptide Y appears to have a similar distribution to that of VLP[10].

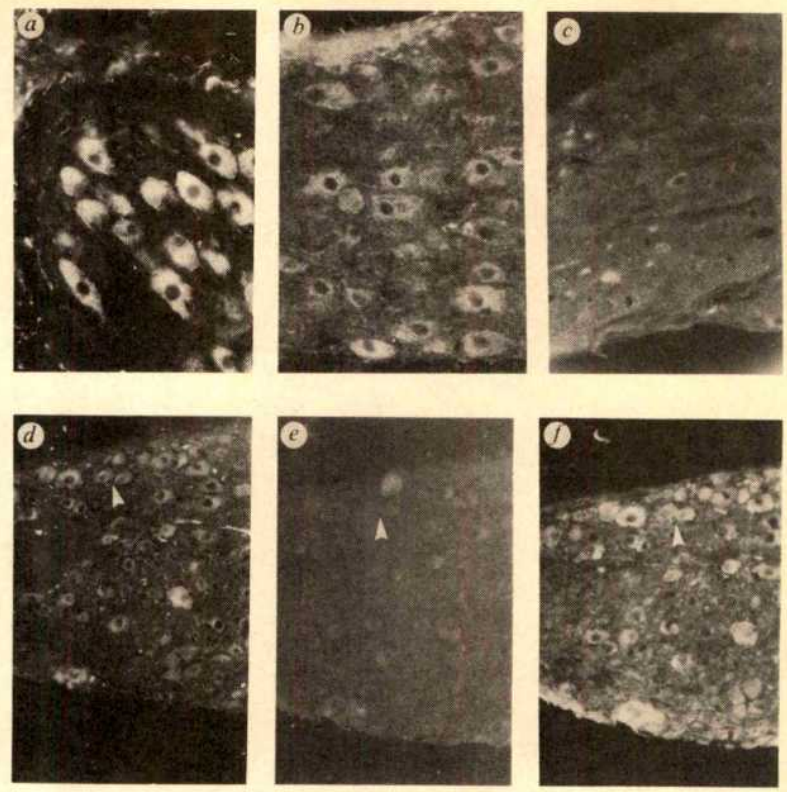

Fig. 2 Immunofluorescence micrographs of vasopressin-like peptide in sympathetic ganglia. *a*, High power view of the edge of a macaque monkey (*Macaca cynomologous*) coeliac ganglion stained for AVP (×154). Note that the nuclei are unstained. *b*, High power view of rat superior cervical ganglion stained for AVP (×154). *c*, Rat superior cervical ganglion examined in a focal plane which shows an AVP-positive nerve fibre plexus surrounding the principal neurones (×77). The principal neurones are unfocused and as a result do not appear clearly stained. *d–f*, A representative double-staining series using the elution method of Tramu *et al.*[18]. *d*, View of rat superior cervical ganglion stained for AVP (×98). *e*, View of the same section after elution of anti-AVP antibody and re-staining with second antiserum (TRITC swine anti-rabbit IgG) to confirm successful elution (×98). The exposure time for *e* was increased 10-fold to enhance the background for identification of neurones. *f*, View of the same section subsequently stained for the noradrenergic marker, dopamine-β-hydroxylase (DBH) using anti-DBH antiserum. All of the neurones stained in *d* are also stained in *f*. Arrows in each of *d–f* illustrate a representative pair of cells that stained for both VLP and DBH.

Methods: Animals were in all case transcardially perfused with a fixative consisting of 4% freshly prepared *p*-formaldehyde in phosphate-buffered saline (PBS). Tissues were removed and post-fixed for 12–24 h in the same fixative, then sunk in 30% sucrose in PBS overnight at 4 °C. Tissues were rapidly frozen and cut on a cryostat at 10 μm onto subbed slides. Slide-mounted sections were incubated with primary antibody for 60 min at 37 °C or overnight at 4 °C in 0.2 ml of PBS containing 0.3% Triton X-100 and 3% swine serum. Antisera (AVP, gift of Drs C. Pol and F. Van Leeuwen) were used at a dilution of 1:100. Sections were rinsed with several changes of PBS at room temperature for 30 min, then incubated for 60 min at 37 °C with secondary antiserum (Dako TRITC-labelled swine antiserum against rabbit IgG, diluted 1:50 in PBS/0.3% Triton X-100/3% swine serum). After rinsing in several changes of PBS, sections were examined by fluorescence optics in a Reichert-Jung Polyvar microscope. Controls included staining with secondary antibody (TRITC swine anti-rabbit IgG) alone and pretreatment of antisera with excess antigen. In the latter case, antisera were incubated in the presence of 10 μg synthetic AVP (CRB Biochemical) or 10 μg synthetic oxytocin (CRB)—both blocked the specific staining, suggesting that the VLP had antigenic characteristics of both AVP and oxytocin. One oxytocin antiserum (gift of Drs C. Pol and F. Van Leeuwen) produced identical results in immunofluorescence to those obtained with the AVP antibody.

Table 2 Production of inositol phosphates in sympathetic ganglia incubated with AVP

	^{3}H (d.p.m. per 10^5 d.p.m. in lipids)				
	GroPIns	InsP	$InsP_2$	$InsP_3$	*n*
a, Control	499 ± 92	2,209 ± 244	886 ± 142	182 ± 21	15
0.32 μM AVP for 15 s	496 ± 116	2,173 ± 281	1,325 ± 93†	458 ± 44*	15
b, Control	1,130 ± 150	6,060 ± 650	1,250 ± 140	670 ± 120	14
0.13 μM AVP for 90 min	1,680 ± 410	160,000 ± 31,000*	29,400 ± 5,850*	3,980 ± 1,220*	9
0.13 μM AVP and 1 μM V_1 antagonist for 90 min	1,150 ± 160	8,740 ± 2,600	1,490 ± 340	450 ± 110	9

a, Superior cervical ganglia from male Wistar rats (~225 g) were desheathed and incubated in 0.3 ml of Krebs–Ringer bicarbonate medium for 2.5 h in the presence of 7.5 μCi [2-^{3}H]inositol (16.9 Ci mmol^{-1}; Amersham) at 37 °C. The ganglia were then incubated in inositol-free medium for a further 1 h. Following incubation with Krebs–Ringer medium containing 10 mM LiCl for 5 min (to inhibit breakdown of inositol 1-phosphate[7]) the ganglia were stimulated with 0.32 μM VP for 15 s. Incubation was terminated with 0.1 ml of 10% (w/v) perchloric acid. The acid-soluble extract was neutralized with 1.53 M KOH (containing 75 mM HEPES to hold the *p*H of the neutralized extract at ~7.0). $KClO_4$ was precipitated at 0 °C and removed by centrifugation. After dilution to 5 ml with 5 mM K^+ tetraborate and 0.5 mM EDTA, the aqueous extract was applied to a small column of Dowex-1 × 10 (100–200 mesh, formate form) and inositol phosphates eluted with 15 ml 5 mM sodium tetraborate/60 mM ammonium formate (to elute glycerophosphoinositol, GroPIns), 20 ml 5 mM sodium tetraborate/150 mM ammonium formate (inositol 1-phosphate, InsP), 20 ml 0.1 M formic acid/0.4 M ammonium formate (inositol bisphosphate, $InsP_2$) and 0.1 M formic acid/1.0 M ammonium formate (inositol trisphosphate, $InsP_3$). Lipids were extracted from the acid-extracted ganglia using chloroform/methanol/12 M HCl (100:200:1 by vol.). The radioactivity of each phosphate ester was determined, and the values were then adjusted to a standard baseline by calculating the accumulation of radioactivity by reference to a standard incorporation of 10^5 d.p.m. into the lipids of one ganglion. The results presented are mean ± s.e.m. of the number of ganglia indicated. Statistical analysis was by an unpaired *t*-test. ***b***, Experimental details as in *a*, except that the V_1-vasopressin antagonist ([1-(β-mercapto-β,β-cyclopentamethylenepropionic acid),2-(*O*-methyl)tyrosine]8-arginine-vasopressin, a gift from Professor M. Manning) was added 5 min before AVP, and incubation was continued for 90 min.

* $P = 0.001$; † $P = 0.02$, difference from appropriate control values.

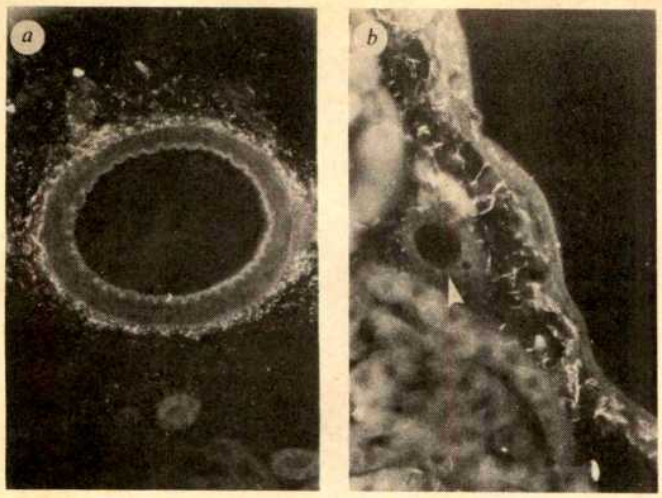

Fig. 3 Immunofluorescence micrographs of vasopressin-like peptide in peripheral nerve fibres of sympathetically innervated tissues. *a*, High power view of cross-section of mouse renal artery stained for AVP (×195). Note the dense innervation in the outer muscle layers. *b*, High power view of a hepatic blood vessel in the hilar region of rat liver (×195). Note that the innervation is highly localized to the vascular smooth muscle and is absent from the region surrounding a bile duct (arrow). Tissues were prepared and stained as described in Fig. 2 legend.

Nonetheless, using antisera to avian pancreatic polypeptide, which cross-react with neuropeptide Y[10], we have found that a smaller proportion of DBH-positive cells stain for avian pancreatic polypeptide than for VLP. In addition, the peripheral fibre distribution of immunoreactive pancreatic polypeptide is restricted to vascular beds, where it is less abundant than that of VLP-immunoreactive fibres. The only neuropeptide which has as wide and extensive a distribution of fibres in blood vessels is calcitonin gene-related peptide[11], but this is apparently of sensory nerve origin. Significantly, calcitonin gene-related peptide appears to have opposite effects to those of AVP[12], suggesting that peptidergic nerves may provide a dual control of peripheral vasculature. The antisera we used to detect VLP showed negligible reactivity with either neuropeptide Y or calcitonin gene-related peptide.

The peripheral release of VLP may explain why a variety of tissues show responses to AVP only at concentrations higher than are normally achieved by secretion into the bloodstream (see ref. 13). Furthermore, the coexistence of VLP with noradrenaline at sympathetic nerve terminals might provide a simple explanation for some non-adrenergic responses elicited by sympathetic nerve stimulation[14]. Such responses, if they are due to VLP, may be conveniently identified by inhibition with selective V_1-receptor antagonists.

Voltage-dependent block by Mg^{2+} of NMDA responses in spinal cord neurones

Acidic amino acids are putative excitatory synaptic transmitters[1,2], the ionic mechanism of which is not well understood. Recent studies with selective agonists and antagonists suggest that neurones of the mammalian central nervous system possess several different receptors for acidic amino acids[3,4], which in turn are coupled to separate conductance mechanisms[5]. *N*-methyl-D-aspartic acid (NMDA) is a selective agonist for one of these receptors[3,4]. The excitatory action of amino acids acting at NMDA receptors is remarkably sensitive to the membrane potential and it has been suggested that the NMDA receptor is coupled to a voltage-sensitive conductance[6–9]. Recently, patch-clamp experiments have shown the voltage-dependent block by Mg^{2+} of current flow through ion channels activated by L-glutamate[10]. We now show using voltage-clamp experiments on mouse spinal cord neurones that the voltage-sensitivity of NMDA action is greatly reduced on the withdrawal of physiological concentrations (~1 mM) of Mg^{2+} from the extracellular fluid. This provides further evidence that Mg^{2+} blocks inward current flow through ion channels linked to NMDA receptors.

We used spinal cord neurones in dissociated cultures prepared from the ventral half or whole spinal cord of 13–14-day-old mouse embryos as described previously[11,12]. After 2–4 weeks in culture neurones were impaled with a pair of microelectrodes containing 1 M CsCl, and voltage-clamped[13]. The recording medium contained (in mM): 143 NaCl, 4.8 KCl, 5 $CaCl_2$, 10 glucose, 10 HEPES and either 0 or 1 mM $MgCl_2$ and was adjusted to *p*H 7.3; sucrose was added to match the osmolarity of the growth medium (325 mOsm). Spontaneous activity and synaptic transmission was reduced by adding 0.6 μM tetrodotoxin (TTX). NMDA (1 mM) was dissolved in bathing medium containing 0, 1 or 5 mM $MgCl_2$ and applied to neurones by pressure using pipettes with tip diameters of 1–2 μm. $CdCl_2$ (1 or 5 mM) and $MgCl_2$ (0.5–5 mM, added iso-osmotically to bathing medium) were applied to individual neurones by pressure using pipettes of tip diameter 4–8 μm. Experiments were performed at 28 °C.

Voltage recording showed that in spinal cord neurones bathed in medium containing Mg^{2+} the membrane potential depolarization evoked by NMDA was accompanied by an apparent resistance increase (Fig. 1*a*). This reflects voltage-sensitivity of the response to NMDA, as hyperpolarizing electrotonic potentials used to measure the membrane resistance result in shut off of the voltage-sensitive conductance activated by NMDA[6–9]. In contrast, when recording in Mg^{2+}-free medium, NMDA-evoked depolarizing responses were instead accompanied by a resistance decrease (Fig. 1*b*), as expected if NMDA acts to increase the membrane conductance to ions with a depolarized reversal

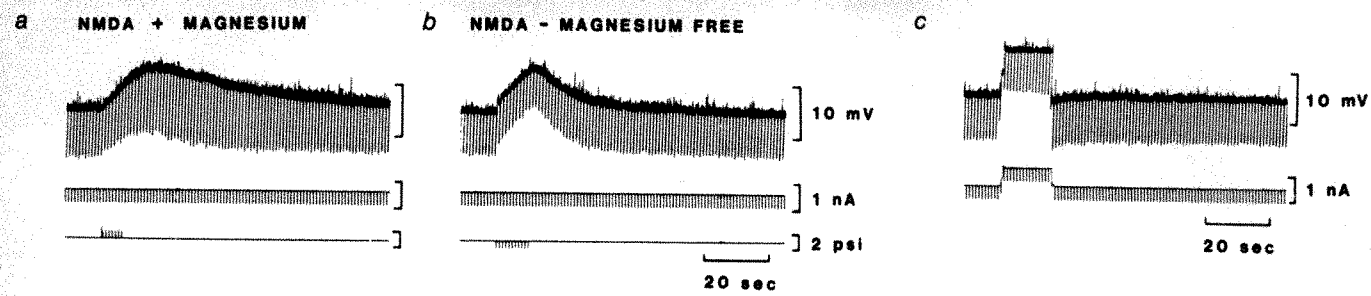

Fig. 1 The apparent membrane resistance change associated with NMDA-evoked depolarizations varies with the extracellular Mg^{2+} concentration. *a*, A depolarizing response evoked by pressure application (110 ms, 1.5 p.s.i., seven pulses) of NMDA (1mM) dissolved in medium containing 5 mM $MgCl_2$; note the apparent membrane resistance increase accompanying the NMDA-evoked depolarization. *b*, The response of the same neurone to pressure application (10 ms, 1 p.s.i., 11 pulses) of NMDA dissolved in medium to which no Mg^{2+} had been added; note the resistance decrease accompanying the NMDA-evoked depolarization. *c*, The response to a d.c. current injection, used to depolarize the membrane potential over a similar range to that occurring during the action of NMDA; note the lack of conductance change in contrast to that recorded during the action of NMDA.
Methods: Records of the membrane potential of a mouse spinal cord neurone in dissociated culture bathed in Mg^{2+}-free medium, and impaled with a pair of microelectrodes filled with 1 M CsCl. One electrode was used to record membrane potential (upper traces); the second intracellular microelectrode was used to inject hyperpolarizing rectangular current pulses (middle traces: virtual ground current monitor); these evoked electrotonic potentials used to measure membrane resistance. A pressure transducer was used to measure the timing of drug application (lower traces). The actual concentration of NMDA and Mg^{2+} at the membrane surface is unknown, but considerable dilution of the solution ejected from the pressure micropipettes is expected to occur.

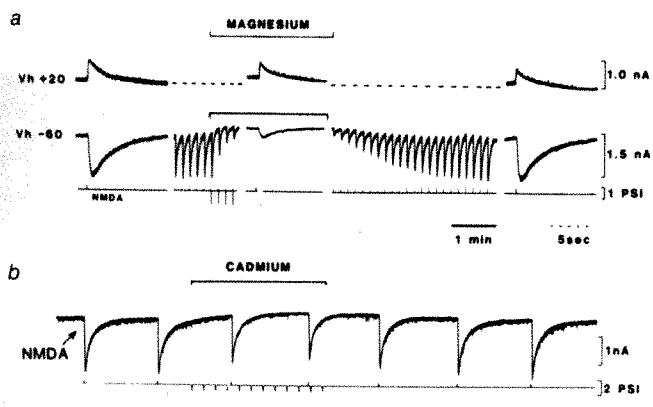

Fig. 2 Mg^{2+} antagonism of NMDA responses is selective and depends on the membrane potential. *a*, Chart records of membrane currents evoked by pressure application (30 ms, 1 p.s.i.) of NMDA (1 mM) in a spinal cord neurone voltage-clamped at holding potentials (V_h) of +20 mV (NMDA currents are outward, that is, upward) and −60 mV (NMDA currents are inward, that is, downward). Pressure application (350 ms, 1.5 p.s.i., five pulses) of Mg^{2+} (5 mM $MgCl_2$) from a second micropipette reversibly antagonized inward NMDA currents recorded at −60 mV, but had no effect on outward NMDA currents recorded at +20 mV. In Mg^{2+}-free medium NMDA currents usually showed slow inactivation, and this is the cause of the small decrease in the amplitude of the NMDA response recorded at +20 mV. *b*, Record obtained for another spinal cord neurone bathed in medium containing 10 mM tetraethylammonium chloride (to suppress outward potassium currents) showing the resistance of NMDA responses (1 mM, 1 p.s.i., 100 ms) to antagonism by doses of Cd^{2+} (1 mM, 1.5 p.s.i., 200 ms, 12 pulses) that completely blocked inward calcium currents evoked by depolarizing voltage jumps (not shown).
Methods: Spinal cord neurones were bathed in Mg^{2+}-free medium and impaled with two microelectrodes (1M CsCl, 60–100 MΩ) for voltage clamping; membrane current was measured with a virtual ground circuit (3 db, 1.6 kHz; upper traces in *a* and *b*). Pressure transducers were used to measure the period of drug application (lower trace in *a*, middle trace in *b*). In *b* the neurone was voltage-clamped at a holding potential of −50 mV, and 30-ms voltage jumps to −10 mV were used to activate voltage-sensitive inward calcium currents (5 nA peak inward current). Application of Cd^{2+} using the protocol described above blocked the inward Ca^{2+} current such that the depolarizing voltage jump then evoked 2 nA of outward leak current (similar to the inward leak current recorded by a hyperpolarizing voltage jump to −90 mV before and during Cd^{2+} application); despite this complete block of the Ca^{2+} current by Cd^{2+}, the NMDA responses recorded in this neurone (*b*) were reduced by only 15%.

potential (for example, Na^+ or Ca^{2+}). To investigate the origin of this effect of Mg^{2+} on the nature of the conductance change evoked by NMDA, it was necessary to perform voltage-clamp experiments.

NMDA evoked inward current (depolarizing) responses in all spinal cord neurones initially voltage-clamped at their resting potential. To study the antagonism by Mg^{2+} of the NMDA response, we recorded from neurones bathed in Mg^{2+}-free medium, and applied both NMDA and Mg^{2+} to individual neurones (see Fig. 2*a*). The antagonism of NMDA responses by Mg^{2+} depended closely on the membrane potential: it was strong at −60 mV, but virtually absent at +20 mV. This antagonistic action of Mg^{2+} showed noncompetitive kinetics, that is, in the presence of Mg^{2+} responses evoked by large doses of NMDA were antagonized to a greater extent than responses evoked by lower doses of NMDA. Such results could be explained if Mg^{2+} ions partially entered and blocked channels activated by NMDA, as the binding of Mg^{2+} would be influenced by the membrane electric field. Recent single-channel recording experiments provide clear evidence for a direct action of Mg^{2+} on ion channels activated by L-glutamate[10].

Experiments using intracellular recording from hippocampal pyramidal neurones have been interpreted to suggest that NMDA activates a voltage-sensitive calcium current[8]. However, cadmium (1 and 5 mM), a potent calcium-channel blocker[14], was much less effective as an NMDA antagonist than Mg^{2+} (see Fig. 2*b*). When 1 mM $CdCl_2$ was added to the recording medium no obvious change in the current–voltage relationship of responses evoked by NMDA was noted. However, in the same neurones for which cadmium had little effect on the response to NMDA, low concentrations of this potent calcium-channel blocker rapidly and completely blocked fast inward calcium currents evoked by depolarizing voltage jumps to −10 or 0 mV. Thus, NMDA does not open the same calcium channels as those gated by membrane potential alone. This result also indicates considerable specificity of the divalent cation-binding site linked to the NMDA-activated channel, with Cd^{2+} having less affinity than Mg^{2+}.

The voltage-dependent blocking action of NMDA responses by Mg^{2+} is sufficient to explain the negative slope of the NMDA current–voltage relationship recorded in media containing physiological concentrations of Mg^{2+}. Figure 3*a* illustrates the voltage dependence of the NMDA-evoked current recorded in medium containing 1 mM $MgCl_2$. The current–voltage relationship of the NMDA response has a negative slope over the potential range −70 to −35 mV, indicating that the conductance activated by NMDA becomes smaller on membrane potential

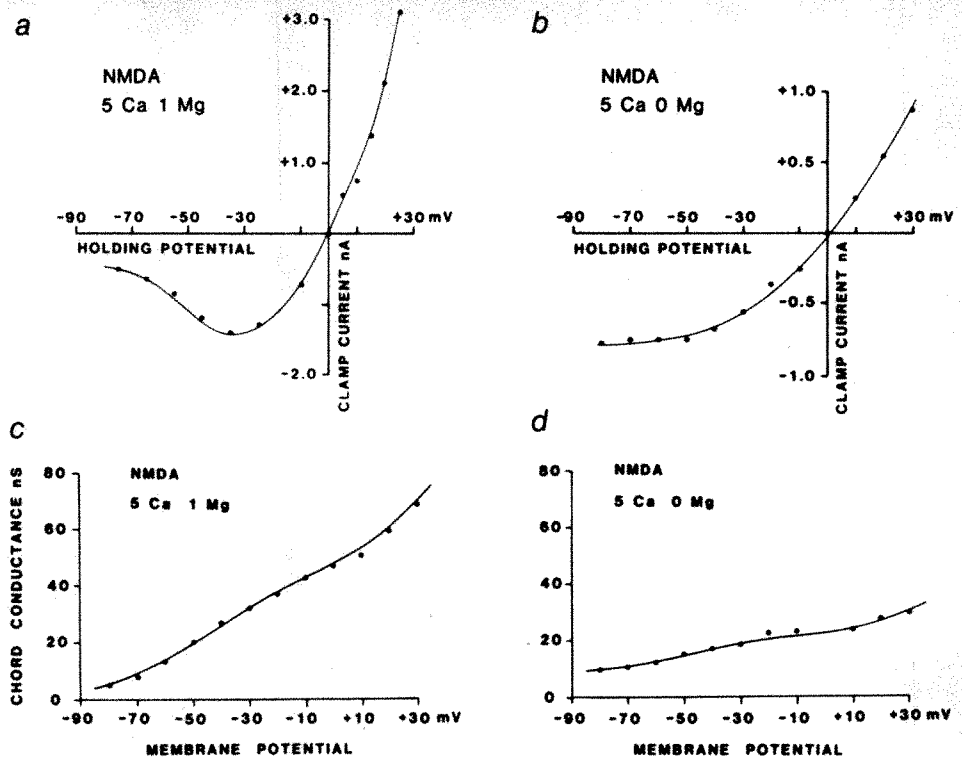

Fig. 3 Voltage-dependence of NMDA responses recorded in spinal cord neurones with and without addition of Mg^{2+} to the extracellular medium. *a*, *b*, Current–voltage plots of the peak amplitude of NMDA current responses, evoked by pressure application of amino acid to voltage-clamped spinal cord neurones, plotted against the holding potential. Each point is the mean of two responses. *a*, Obtained from a neurone bathed in medium containing 1 mM Mg^{2+}; note the negative slope of the graph between −35 and −75 mV which indicates voltage sensitivity of the NMDA response *b*, Obtained from a neurone bathed in medium to which no Mg^{2+} was added; note that the slope is positive at all membrane potentials. The residual voltage sensitivity of the NMDA response recorded in Mg^{2+}-free medium may arise from contamination of the recording medium with trace amounts of Mg^{2+} due to incomplete exchange of the Mg^{2+}-containing growth medium; additional sources of Mg^{2+} contamination may include binding of Mg^{2+} to neuronal membranes, and leakage of Mg^{2+} from the interior of cells. It is also possible that Ca^{2+} has a weak Mg^{2+}-like effect. *c*, *d*, Chord conductance–voltage plots of the NMDA responses in *a* and *b*, respectively. Note the strong outward rectification of the conductance activated by NMDA in medium containing 1 mM $MgCl_2$: the rectification ratio of the conductance at +20 mV divided by that at −70 mV is 12.2. In Mg^{2+}-free medium the NMDA-activated conductance is considerably less voltage-sensitive, and the rectification ratio recorded over the same membrane potential range is only 2.6.

Methods: Neurones were voltage-clamped as described in Fig. 2 legend and NMDA responses recorded as the membrane potential was changed by 10-mV increments. The chord (ionic) conductance membrane potential relationship was derived as follows: for a parallel conductance model the current flow through an agonist-operated channel (I_x) is related to the conductance of the agonist-operated channel (G_x) by the equation $I_x = G_x(E_m - E_x)$, where E_x is the reversal potential of the current flowing through the agonist-activated channel and E_m is the membrane potential. Thus, we could calculate the relationship between the membrane potential and the NMDA-activated conductance from our measurements of the peak amplitude of the NMDA-evoked current and its reversal potential.

hyperpolarization (see Fig. 3*c*). In contrast, when $MgCl_2$ was omitted from the recording medium the current–voltage relationship of the response evoked by NMDA did not show the characteristic negative slope behaviour described above. Instead the peak inward current evoked by NMDA increased slightly as the membrane was hyperpolarized over the potential range −40 to −70 mV (see Fig. 1*b*). Thus, removal of Mg^{2+} from the recording medium greatly reduces the voltage sensitivity of the conductance activated by NMDA (see Fig. 3*d*).

Previous experiments with NMDA have been interpreted to suggest that this amino acid has a regulatory action on an undefined voltage-sensitive conductance. Initially it was thought that NMDA closed potassium channels[14,15]. Subsequent studies suggested activation by NMDA of a voltage-sensitive calcium[8] or sodium[7,9] conductance. However, our results and those of Nowak *et al.*[10] suggest that physiological concentrations of Mg^{2+} block ion channels linked to NMDA receptors. As the block is voltage-dependent it seems probable that magnesium ions enter the channel and sense the membrane electric field. Channel block by several species of either charged or uncharged molecules is known to occur in a wide variety of membrane ion channels[17–19]; the present results extend this situation to ion channels linked to excitatory amino acid receptors. The action of Mg^{2+} at physiological concentrations suggests that acute or chronic changes in the extracellular Mg^{2+} concentration could be potent modulators of neuronal excitability *in vivo*.

We thank Dr Philip Nelson for allowing us to work in his laboratory, Sandy Fitzgerald for preparing the cultures, and Professor J. S. Kelly for his comments on our manuscript. M.L.M. is a Beit Memorial Fellow and thanks the Royal Society for a study visit award to work at NIH.

Spectral sensitivity of single cones in the retina of *Macaca fascicularis*

B. J. Nunn, J. L. Schnapf & D. A. Baylor

Department of Neurobiology, Stanford Medical School, Stanford, California 94305, USA

Colour vision depends on the wavelength-dependent absorptions of three different photolabile pigments each located in a particular type of retinal cone. The spectral absorption of primate cones has been examined by microspectrophotometry[1–7], but this method gives information only at wavelengths where the absorption is relatively strong. Here we have analysed the absorption of two of the cones over a wider range of wavelengths by recording their electrical responses to monochromatic light. The observations were made on the retina of the monkey *Macaca fascicularis*, an animal thought to have cone pigments like those of man[8]. The measured spectral sensitivities of the red-sensitive ('red') and green-sensitive ('green') cones agreed well with estimates[9] of the cone pigment absorptions derived from colour-matching experiments in humans. At long wavelengths the sensitivity of the red cones was found to decline more rapidly than that of the green. This behaviour, attributable to the cone pigment molecules themselves, explains the paradoxical hue shift[10], in which a light of very long wavelength is perceived to be identical to a light of shorter wavelength.

A glass suction electrode was used to record photocurrent from a single cone outer segment projecting from a chopped piece of retina[11,12]. The recording chamber was continuously perfused with bicarbonate-buffered Locke's solution equilibrated with 95% O_2, 5% CO_2, and the fluid in the chamber kept near 37 °C. Light stimuli were made 'monochromatic' by interference filters of half bandwidth 10 nm. Flash strength was varied by a calibrated series of neutral density filters, and the unattenuated flux density at each wavelength was determined at the end of each day. Spectral sensitivity (the reciprocal of the flash photon density required to evoke a response of constant amplitude) was determined by the method of Naka and Rushton[13]. To prevent errors resulting from progressive bleaching or movement of the cell in the electrode, the sensitivity at each wavelength was measured between runs at 500 nm and expressed relative to the average value at 500 nm. Roughly 1,000 flashes were delivered while determining the entire spectral sensitivity over a period of about 1 h. The light was applied to the outer segment transverse to its long axis. Because of the short path length for transverse incidence, self-screening of the pigment can be neglected and measured sensitivity should be proportional to the molecular extinction coefficient of the pigment in the cone.

Outward-going photocurrents up to 20 pA in saturating amplitude were elicited by brief flashes. Figure 1*a* shows a family of flash responses from a red cone and Fig. 1*b* a similar family from a green cone. Flash strengths were increased by factors of about two. The photocurrents were diphasic, with the recovery phase marked by an underswing. The time to peak of the average response to a dim flash was 60–100 ms in six of the seven cells studied, while in one unusually slow green cone it was 150 ms. The small sample of cells provided no evidence for a systematic difference between the kinetics of the responses of red and green cones. The cone responses were, however, two to three times faster than those recorded from single rods in similar preparations from this species[12]. As expected from the principle of univariance[13], the waveforms of a cone's responses to any two monochromatic lights were identical when the light intensities were adjusted to give responses of equal amplitude.

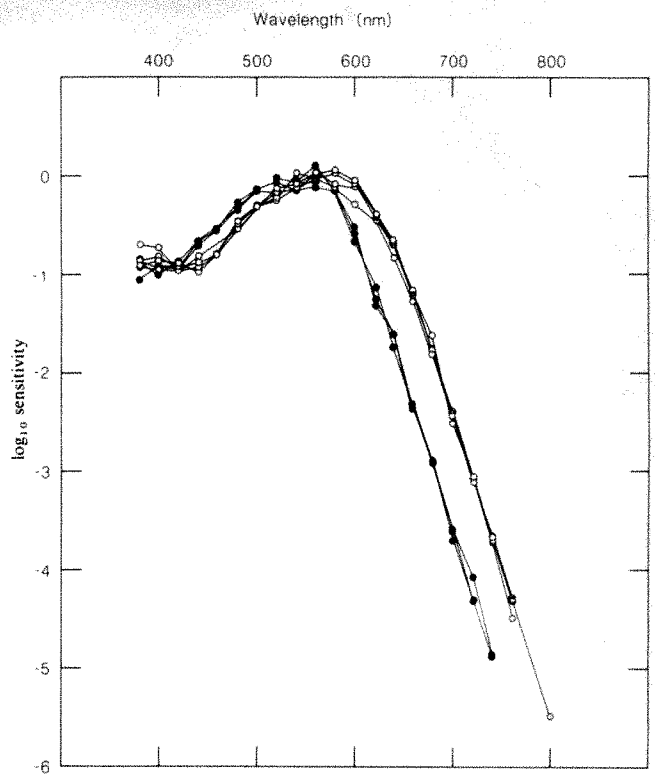

Fig. 2 Collected spectral sensitivities from seven cones. Open symbols, red cones, closed symbols, green. Lines drawn to connect each set of points. Curves positioned vertically to minimize the difference between curves in each population and to give a maximum near log $S = 0$. Sensitivity determined as described in text. Results from two male monkeys. One red cone was from the foveal region, all others from the peripheral retina.

Spectral sensitivity curves from seven cells are plotted in Fig. 2. There was no pre-selection of data; a cell was studied if it gave large responses and did not have the physiological characteristics of a rod[12]. The results fell into two groups with spectral maxima at roughly 540 nm (green cones) and 570 nm (red). Microspectrophotometry has given values near 535 and 567 nm for the average peak absorption of these two types of cones in *Macaca fascicularis*[4,5] and similar values (531, 558 nm) in human

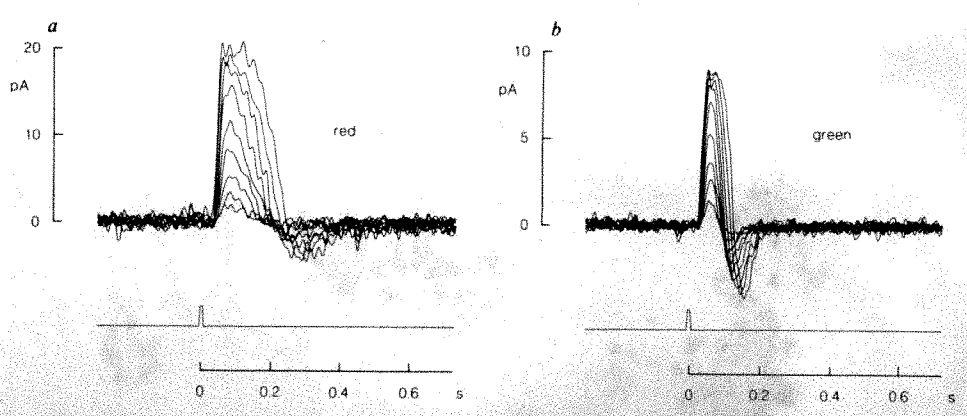

Fig. 1 Superimposed responses to brief flashes of increasing strength from a red cone (*a*) and a green cone (*b*) of the peripheral retina. Outward change in membrane current plotted as a function of time after the flash. Light monitor trace below. Each response averaged from up to 10 sweeps. Flash strengths were increased by nominal factors of 2. In *a*, flashes were at 579 nm and the intensities were raised from 292 to 40,210 photons μm^{-2}; in *b*, 559 nm and 453 to 65,640 photons μm^{-2}. Bandwidth, 0–50 Hz. Temperature, 37 °C.

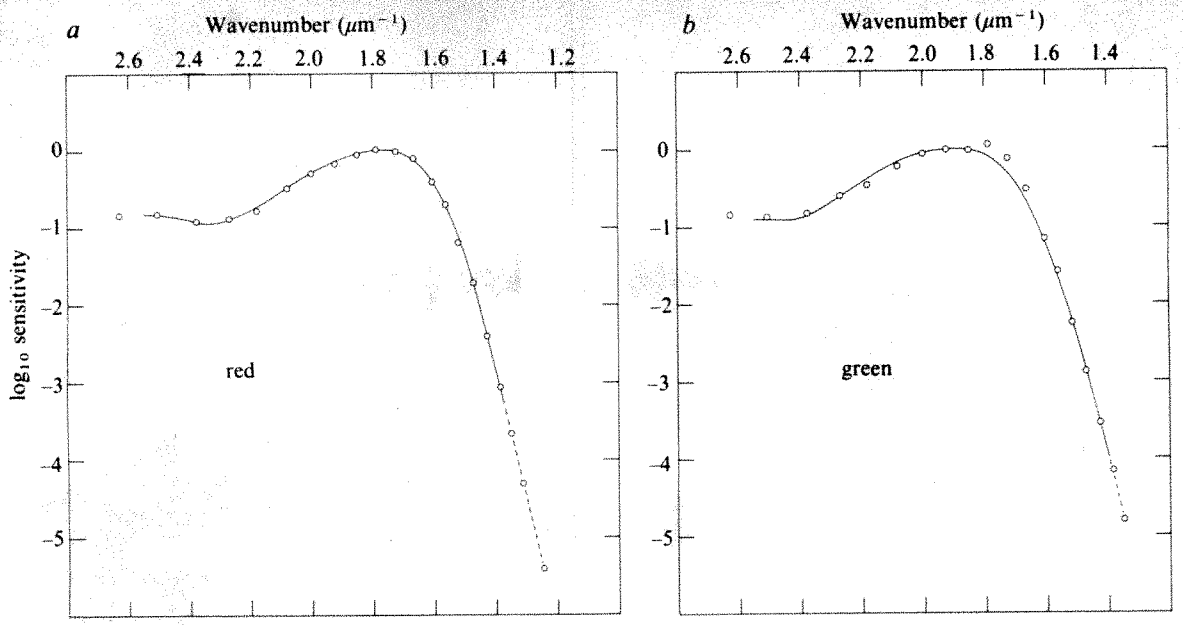

Fig. 3 Averages of $\log_{10}$ spectral sensitivities from the four red and three green cones of Fig. 2, plotted on a wavenumber scale. Solid curves drawn according to estimates by Estevez[9] of the relative spectral absorption of red and green cone pigments in humans. Each set of points positioned on the vertical scale to best fit the curves, which have maxima at 1.79 μm^{-1} (560 nm) in *a* and at 1.85 μm^{-1} (540 nm) in *b*.

cones[7]. Blue cones have not been encountered in the present work. From curves of averaged sensitivity, the spectral bandwidths at half height were estimated as $0.37 \pm 0.2\ \mu m^{-1}$ (red) and $0.41 \pm 0.2\ \mu m^{-1}$ (green); these values are comparable to those obtained by microspectrophotometry on cones of the same species[5].

The averaged spectral sensitivities of the red and green cones are plotted on a wavenumber scale in Fig. 3. The continuous curves show derived spectral absorptions in the red and green pigments as obtained by Estevez[9] from human colour-matching experiments; the dashed extensions of the curves at low wavenumber have been drawn by eye. Estimates by Smith and Pokorny[14] were similar but did not fit our measurements as well at short wavelength. The psychophysical estimates were calculated on the König assumption[15] that dichromats simply lack one of the three pigments present in normal trichromats. The agreement between the derived and measured sensitivities supports this assumption and further emphasizes the similarity of the primary colour mechanisms in the cynomolgus monkey and man.

The gradient of descent of log sensitivity at long wavelength was steeper for the red cones than for the green as predicted on theoretical grounds by Lewis[16] in 1955. Figure 4 shows this in a wavenumber plot. The lines were obtained by linear regression of $\log_{10}$ sensitivity on wavenumber, using the points at the four lowest wavenumbers. For the red cones, regression analysis gave a gradient of $17.7 \pm 0.4\ \mu m$ (slope ± standard error; correlation coefficient $r^2 = 0.995$), while for the green it was $15.5 \pm 0.6\ \mu m$ ($r^2 = 0.986$). These gradients are less than the value of 20.0 μm derived by Stiles[17] on the assumption that the ground state vibrational energies of the pigment molecules are Boltzmann-distributed. Within experimental error the gradient of decline of the red sensitivity at long wavelength is the same as the gradient of human foveal sensitivity (17.4 μm)[18,19], as expected if at threshold only red cones mediate foveal sensation in this region of the spectrum. Because the sensitivity gradient of green cones at long wavelength was less steep, the ratio of red/green sensitivities was maximum at roughly 700 nm and less on either side. This explains the psychophysical observation that a monochromatic light beyond 700 nm has the same hue as that at a characteristic wavelength below 700 nm[10,20]. Estimates of the wavelength pairs that should give the same ratio of excitation in the red and green cones were determined from

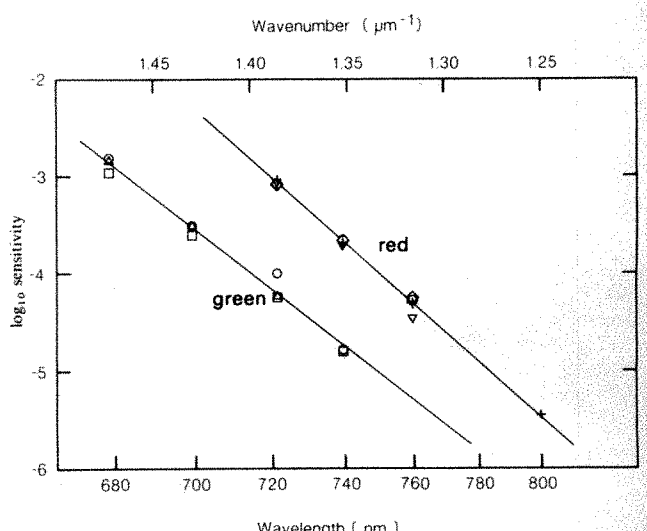

Fig. 4 Decline of sensitivity at low wavenumber. Long wavelength points from Fig. 2 replotted on a wavenumber scale, with results from each cell denoted by a different symbol. Lines obtained from the linear regression analysis described in the text.

the present results and found to be similar to the psychophysical isochromes. This suggests that the perceptual phenomenon may result in a simple way from the characteristics of absorption in the cone pigment molecules.

Localized Ca^{2+} and calcium-activated potassium conductances in terminals of a barnacle photoreceptor

N. Stockbridge & W. N. Ross

The Marine Biological Laboratory, Woods Hole, Massachusetts 02543, USA

Calcium channels are found in the presynaptic terminals of neurones, where they have a key role in synaptic transmission[1]. They are also found in the somata of many cells[2], in dendrites[3] and along a few axons[2,4]. In no cell is the actual distribution of these channels known in detail, because there are no known toxins or other agents suitable for labelling calcium channels, and the current through these channels is usually too small to be quantified with extracellular electrodes. However, several experiments have suggested that the density of the channels is less in the axon than in the cell body or terminal region[5–8]. Here we have used the indicator dye Arsenazo III in conjunction with an array of photodetectors to examine the spatial influx of calcium in the presynaptic terminal region of the giant barnacle, *Balanus nubilus*. In these cells, calcium entry occurs in a restricted region less than 50 μm in length, which corresponds closely to the region of synaptic contact with second-order cells. Outside this area the magnitude of calcium entry is reduced at least 50-fold. With reasonable assumptions it follows that the calcium channel density is equally localized. In addition, we demonstrate that these cells have a calcium-activated potassium conductance. Since calcium entry is restricted to the synaptic zone, this conductance must be effective only in this region.

Optical experiments using the calcium indicator dye Arsenazo III can show changes in cytoplasmic calcium concentration due to opening of calcium channels[9]. Because calcium ion diffusion within the cytoplasm is slow ($D \approx 3 \times 10^{-7}$ cm^2 s^{-1})[10] the channels must be located close to the site of calcium concentration increase. We have used an array of photodetectors[11,12] with a spatial resolution of 25 μm in the plane of the preparation to measure simultaneously the magnitude and time-course of calcium transients at many positions. Previous experiments have used a single detector and only one looked for the extent of calcium entry: Miledi and Parker[13], recording successively from two positions in the squid presynaptic terminal with a resolution of 500 μm, showed that calcium entry was greater at the synapse than at a position away from this region.

The photoreceptors of the giant barnacle are well suited for a study of calcium channel localization. From the ocellus each of the four photoreceptors sends a 10–15 mm long axon to the supraoesophageal ganglion which then bifurcates, ending in two restricted synaptic regions on the medial side of each hemiganglion (Fig. 1). The dimensions of this area are typical of many synaptic regions in both vertebrates and invertebrates and are much smaller than the squid giant synapse. The axon can be impaled along its length but the synaptic zones are too small for intracellular recording[14].

Fig. 1 Photoreceptor axon and terminal region filled with Lucifer yellow and photographed with fluorescence optics. The preparation has been fixed and cleared. The dimmer masses on each side of the terminals are the two hemi-ganglia of the supraoesophageal ganglion. The microelectrode for injecting Arsenazo III and Lucifer yellow was inserted in the axon at a point near the top of the figure. The scale bar represents 150 μm, which is also the diameter of the field sensed by the 32 elements of the photodiode array.

In normal physiological saline (461 mM NaCl, 8 mM KCl, 20 mM $CaCl_2$, 12 mM $MgCl_2$, 5 mM HEPES, *p*H 7.6) the receptor potential is conducted decrementally to the synapse. In saline containing ≥ 5 mM tetraethylammonium (TEA), a depolarizing potential will generate a calcium-dependent action potential followed by an after-hyperpolarization lasting several seconds[7]. In experiments with two microelectrodes in the axon, the amplitude of both the action potential and the undershoot were found to be larger when recorded from the electrode closer to the terminal, suggesting that the calcium channels might be more concentrated in the terminal region[7]. Pharmacological experiments gave further evidence that there were more channels in the terminal but did not improve the spatial resolution[8].

For our experiments the photoreceptor axon was impaled near the bifurcation with an electrode containing 75 mM Arsenazo III (Sigma, 8891). The dye was iontophoresed into the axon and allowed to diffuse for 15 min into the fine presynaptic terminals in each hemi-ganglion. The terminal region was imaged onto a square array of 32 photodiodes. In response to a depolarization produced by a brief light flash or electrically via the microelectrode, an absorbance increase at 660 nm was detected by photodiodes positioned over each terminal. The absorbance changes had a biphasic action spectrum consistent with an increase in ionized calcium interacting with the dye[15]. In other experiments the absorbance changes were completely eliminated when the 20 mM Ca^{2+} in the saline was replaced with 2 mM Ca^{2+} + 18 mM Co^{2+} or when 30 mM $CoCl_2$ was added to the saline. The same solutions also block the calcium-dependent action potential which can be elicited when TEA is added to the saline. These observations suggest that the absorbance changes are caused by calcium entering through membrane channels which have a pharmacology typical of other voltage-sensitive calcium channels[16].

Figure 2 shows the change in absorbance at 660 nm detected by each of 32 elements of the photodiode array. The signals have been placed over the outline of a fluorescence photograph of the terminal which was filled with Lucifer yellow after the Arsenazo experiment was completed. The largest signals are located over the final 50 μm of the terminal and are resolved with a signal-to-noise ratio of greater than 50:1. The magnitude declined by a factor of 10 within 50 μm of the terminal and no signal was detected above noise level when the array was moved to cover the axon region at the point of bifurcation in the

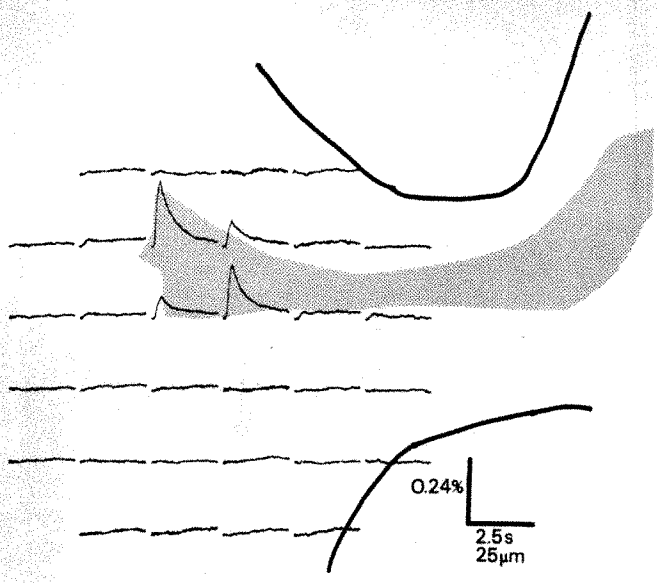

Fig. 2 Spatial distribution of Arsenazo III absorbance changes in the photoreceptor presynaptic terminal region. The stippled area traces the outline of the presynaptic terminal determined from a photograph of the live Lucifer yellow-filled photoreceptor. The heavy lines are the boundary of the ganglion. Each trace shows the stimulus-induced change in light intensity detected by a photodiode element. Fifty sweeps were averaged. The change in absorbance ΔA is proportional to $\Delta I/I$ as long as the dye does not absorb a significant fraction of the incident light, as was true for these experiments. The photoreceptor was stimulated with 250-ms depolarizing pulses through the same microelectrode used to iontophorese dye into the cell. Note that the absorbance increases during the stimulus pulse and declines to baseline with a time constant of about 1.5 s, more than five times faster than that measured at the presynaptic terminal of the squid giant synapse[22]. **Methods:** To make these measurements, the ganglion was imaged onto the photodiode array using a ×40 water-immersion lens (n.a. = 0.75). The incident wavelength was selected with interference filters having a bandwidth of 30 nm. The current output of each photodiode was converted to voltage and the d.c. component of this signal was subtracted using a sample-and-hold circuit. This signal was RC filtered with a time constant of 10 ms, amplified (×2,000), multiplexed and digitized into an LSI-11/23 computer for further analysis and display.

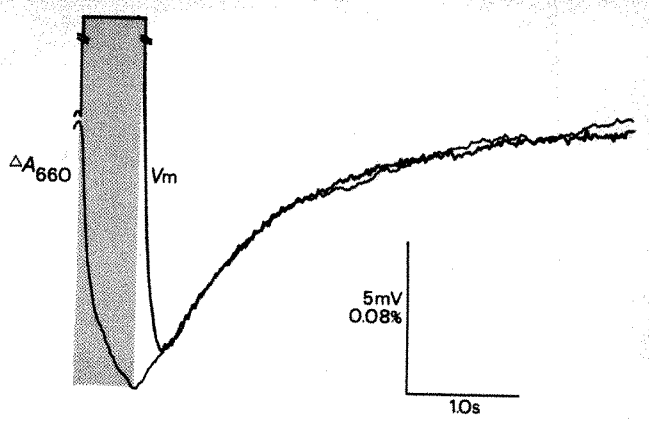

Fig. 3 Comparison of the time course of the undershoot following a depolarizing pulse (stippled area) with the simultaneously measured change in absorbance of Arsenazo III. The signal from one of the photodiodes located over the terminal region has been inverted and scaled to make the two curves coincide at the time when the potential undershoot is largest. The peak of the calcium signal coincides with the end of the depolarizing pulse. However, the peak of the undershoot is not detected at the electrode until about 100 ms later because of the time and space constants of the cell. The magnitude of the depolarizing pulse was not determined; bridge stimulation was used. Ten sweeps were averaged.

commissure. The smaller signals around the central region are probably the result of light scattering, as the signals to the top and left of the terminal come from areas where there is no terminal membrane and hence no dye. Tests with a 20-μm diameter pinhole placed under the ganglion showed that the tissue scattered the transmitted light with almost the same distribution as the absorbance signal. In addition, all of the signals have the same time course, consistent with their originating from a single locus.

In five of six experiments made using the 25-μm spacing of the grid elements, we found that the calcium signals were similarly localized to a 25–50 μm region at the end of the presynaptic process. This corresponds closely to the region of contact with the second-order cells determined anatomically[17]. In one experiment the zone of calcium entry extended over 100 μm. This may indicate that some calcium channels exist outside the synaptic zone. A more likely explanation is that the synaptic zone itself is larger than 50 μm in some preparations. The presynaptic arborization shown in Fig. 1 is an example of a cell with a larger than average arborisation. It is unlikely that the absence of signals over the region away from the terminal is due to unsusually high buffering of calcium because direct iontophoretic injection of calcium into axons previously filled with Arsenazo III gave large signals.

How does the channel density in the terminal compare with that in the rest of the axon? If we assume that the concentration of Arsenazo III is uniform in the terminal region (reasonable since the dye is injected several hundred micrometres from the terminal) and that the absorbance change is proportional to the amount of calcium entry (as shown directly by Miledi and Parker at the squid synapse[13]), it follows that the intensity change detected by each photodiode element is proportional to the amount of calcium entering the cell in the image plane of each element. Since the calcium enters through voltage-sensitive channels and the terminal is uniformly depolarized by the electrode, the signal size is proportional to the number of calcium channels. This proportionality can be extended to channel density if the amount of membrane is the same under each grid element. For this synapse, an examination of photographs of cells filled with Lucifer yellow indicates that there is probably less membrane area per grid element at the synapse than over the axon. Making the conservative assumption of equality, we conclude that the density of calcium channels in the terminal is at least 50 times higher than in the axon. This restricted distribution of calcium channels is reminiscent of the localization of acetylcholine receptor channels on the postsynaptic membrane of the neuromuscular junction[18].

The undershoot following a calcium-dependent action potential elicited in TEA saline has a reversal potential dependent on external potassium concentration and a magnitude dependent on external calcium concentration[19], suggesting that it is caused by a calcium-activated potassium conductance. Further evidence for this conclusion comes from a comparison between the Arsenazo III signal and the undershoot elicited with a depolarizing pulse in normal saline (Fig. 3). After the first 100 ms following the depolarizing pulse the potential returns to baseline with the same time course as the reduction in intracellular calcium. Because the voltage is always far from the potassium equilibrium potential, the conductance change also follows the time course of the intracellular calcium concentration change. This correspondence is expected if the average calcium concentration in the terminal parallels the concentration directly under the membrane where the conductance is controlled[20]. We have modelled the diffusion of calcium within volumes typical of the photoreceptor terminal using the methods of Zucker and Stockbridge[21]. The time to reach 90% of the equilibrium after a pulse of calcium enters the terminal was found to be $t \approx kBr^2$ where $k = 4 \times 10^{-4}$, B is the ratio of the diffusion constant of calcium in water to that in cytoplasm, and r is the radius of the synaptic terminal assumed to be a cylinder. If $B = 20$ (ref. 10)

$r = 4$ μm (ref. 17), then $t = 128$ ms, which is fast compared with the observed time course of calcium removal.

Since calcium entry is restricted to the terminal, the calcium-activated conductance change is similarly restricted. The potassium channels themselves may have a wider distribution, but those away from the terminal are not activated.

Light-dependent calcium release from photoreceptors measured by laser micro-mass analysis

Walter H. Schröder

Institut für Neurobiologie, Kernforschungsanlage Jülich GmbH, D-5170 Jülich 1, FRG

Gordon L. Fain*

Department of Ophthalmology, Jules Stein Eye Institute, UCLA School of Medicine, Los Angeles, California 90024, USA

Yoshikami and Hagins[1] first suggested that calcium is sequestered within membranous disks in the outer segments of vertebrate rods and that the bleaching of visual pigment molecules by light causes the release of Ca from the disks. Once released, the Ca was postulated to bind to Na^+ channels or carrier molecules in the plasma membrane to produce the electrical response. This theory, termed the 'calcium hypothesis', is supported by much evidence[2–5] but remains controversial, largely because of the difficulty in measuring calcium in rods and of demonstrating light-induced release[6–14]. Here we describe direct measurements of total rod Ca using a new microprobe method, called laser micro-mass analysis, or LAMMA. Using this technique, we show that rods contain large amounts of Ca concentrated in their outer segments. Physiological levels of illumination produce a graded efflux of rod Ca content, amounting to about 10^4 ions per rhodopsin molecule bleached in dim light. As light does not change the rate of Ca influx, the total Ca content of the rod decreases. In bright light, as much as half the total Ca leaves the rod during only 1 min of illumination.

The retinas of toads (*Bufo marinus*) dark-adapted for 3 h or more were removed either in darkness (with the aid of an IR converter) or in dim red light and were placed photoreceptors upwards on a Millipore filter. In the experiments of Figs 1–3, where Ca was measured only for dark-adapted rods, the dissected retina was immediately shock-frozen and processed as described in Fig. 1 legend. In the experiments of Fig. 4, where the rods were exposed to light, we first measured the electroretinogram from the isolated retina as a control for the light sensitivity of the preparation. We then sliced each retina into eight wedge-shaped pieces. One of these was immediately processed as a control, and the others were exposed to oxygenated Ringer's in darkness and in light for specified periods of time as described in Fig. 4 legend.

Ca content was analysed using a LAMMA-500 (Leybold–Heraeus, Köln, FRG). A complete description of this instrument is given elsewhere[15]. Briefly, the LAMMA-500 uses two lasers,

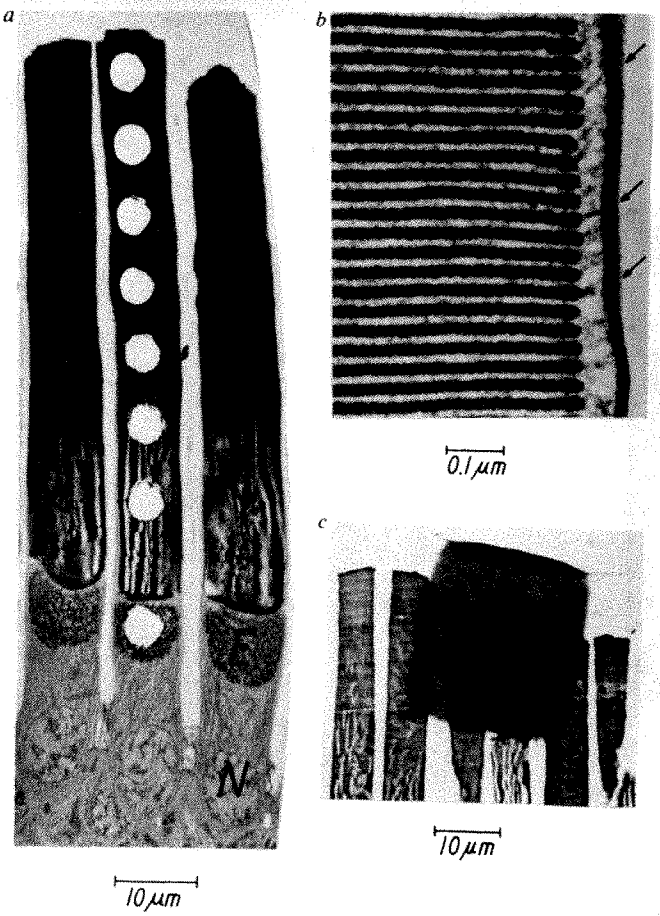

Fig. 1 Morphology and fine structure of rods prepared for LAMMA measurements. *a*, Low-power electronmicrograph of rods showing the holes produced by the high-energy laser of the LAMMA apparatus. OS, outer segment; E, ellipsoid region containing mitochondria; N, nucleus. *b*, High-power electronmicrograph taken from the distal half of the outer segment. Note the fibrillar-like densities between the disks, and the fibrillar connections between the disks and the plasma membrane (arrows; see refs 20, 21). *c*, Calibration of Ca content (see ref. 16). A 600-mesh electron microscope grid was placed directly on top of a section of retina. The section was placed, together with pellets of CaF_2, in a vacuum beam evaporator at a pressure of $<10^{-6}$ mbar. A film of CaF_2 was then deposited through the holes of the electron microscope grid onto the outer segments to produce a checkerboard-like pattern across the section. The thickness of the film was measured with a quartz crystal monitor (Balzers, QSG, 2010), which in turn was calibrated by weighing a series of standard films on a microbalance.
Methods: The tissue was prepared by rapid immersion in melting Freon at −150 °C and then in liquid N_2. In this figure and in most other experiments the frozen pieces were then transferred to vials containing dry acetone and 0.5% OsO_4 at −194 °C and were slowly warmed over the course of several days to permit the acetone gradually to replace the water in the tissue. In a few cases (for example, Fig. 2), the water in the tissue was removed by freeze-drying below −75 °C at 10^{-6}–10^{-7} mbar for 2 days. The tissue was embedded in an Epon–Araldite mixture and sectioned at a thickness of 0.5 μm on a Reichert Ultracut ultramicrotome.

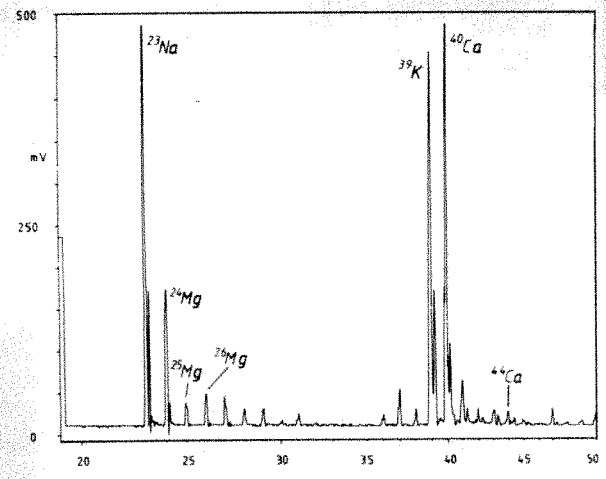

Fig. 2 LAMMA spectrum obtained for a dark-adapted rod outer segment. The spectrum was obtained from a retina shock-frozen immediately after the dissection and freeze-dried (see Fig. 1 legend). Spectra obtained from rods prepared by freeze-substitution were similar.

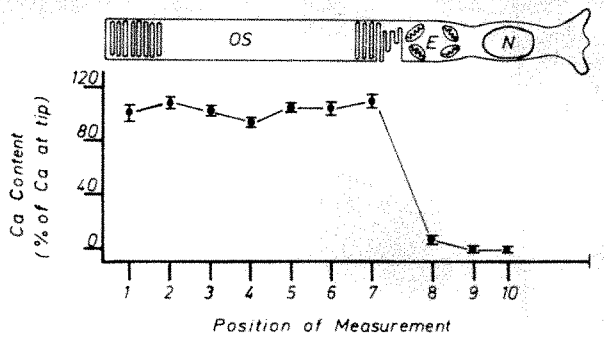

Fig. 3 Distribution of Ca content as a function of distance down the rod. For the outer segment (positions 1–7), seven equally-spaced measurements were made from each of 30 dark-adapted rods. The area within the ^{40}Ca peak at each position was then calculated on a computer after background substraction. The values for each of the 30 rods were averaged, and the means (±s.d.) were expressed as a percentage of the value at position 1. For the inner segment, separate measurements were made in each of seven dark-adapted rods for the ellipsoid (position 8), the cytoplasm between the ellipsoid and the nucleus (position 9) and for the nucleus (position 10). Means (±s.d.) of the ^{40}Ca signals are expressed as a percentage of the mean ^{40}Ca signal obtained at position 1 in the outer segment. At positions 9 and 10, the Ca was below the limit of detection of our method (50 μmol l^{-1}).

a low-power He–Ne laser and a high-power Nd:YAG pulse laser, which are colinear. The tissue sections (usually supported on an electron microscope grid) are placed in a vacuum chamber on the stage of a light microscope. The stage is moved to position the low-power laser over a region of interest, and the high-power laser is then activated to vaporize a small area 1–5 μm in diameter. Ions formed during the vaporization are accelerated into the field of an electromagnetic lens and analysed with a time-of-flight mass spectrometer.

Figure 1*a* illustrates the typical appearance of shock-frozen rods following sectioning and analysis of Ca content. The holes in the rod were produced by the high-energy laser of the LAMMA apparatus. Preservation of the tissue was best in the distal half of the outer segment, as this was directly exposed to the freezing medium (see Fig. 1*b*). In the proximal outer segment and in the inner segment there was evidence of structural damage, probably due to the formation of ice crystals. However, it was still usually possible to identify the mitochondria forming the ellipsoid region (Fig. 1*a*, E) and the nucleus (N).

Figure 2 shows the low atomic-weight region of a LAMMA spectrum from a dark-adapted rod outer segment. As the microplasma produced from the tissue by the high-energy laser contains almost exclusively singly-charged particles[15], the m/e ratios in the spectrum give the atomic weights of the analysed mass directly. The peaks for ^{23}Na, ^{39}K and the various isotopes of Mg can be clearly identified, although we cannot, with the procedures presently used, quantify the concentration of these elements in the rods. There is also a prominent peak for ^{40}Ca and a smaller peak for the less common ^{44}Ca (2% natural abundancy).

To relate the amplitude of the ^{40}Ca signal to the actual concentration of Ca within the rod, we vacuum-deposited a thin film of CaF_2 directly onto the tissue section[16], as described in Fig. 1 legend. The ratio of the LAMMA signals from rods covered by the thin film and from rods not covered by the film, measured from cells in the same section, was used to determine the total number of Ca atoms within the sampled area. To calculate the calcium concentration in the rod, we also needed to know the thickness of the section. This was determined by vacuum-evaporating platinum on both sides of the section. The section was then re-embedded, resectioned at an oblique angle, and viewed in the electron microscope. The calibration procedure was performed independently on sections of retinae from two dark-adapted animals, giving 4.4±1.8 mmol Ca per l of tissue volume (mean±s.d.) in one case and 4.7±1.8 mmol l^{-1} in the other. This represents approximately $3–5\times10^9$ Ca atoms per rod outer segment or 1–2 Ca atoms per rhodopsin[17].

As the LAMMA can produce holes that are only a few μm in diameter (see Fig. 1*a*), we used this technique to investigate differences in Ca content between different regions of the rod. These measurements (Fig. 3) show that most of the Ca in the rod (>95%) is concentrated within the outer segment. We could detect no significant variation in Ca content along the outer segment, despite large differences in the preservation of the tissue. In the inner segment, Ca could be detected only in the mitochondrial-rich ellipsoid region (250–500 μmol l^{-1}). The decrease in Ca in the inner segment could conceivably have been caused by ice crystal damage in this region. However, we could see no obvious difference in preservation between the innermost outer segment (position 7 in Fig. 3) and the outermost inner segment (position 8), even though the Ca content changed dramatically here in every rod we examined.

Figure 4 shows the effect of light on the Ca content of the rod outer segment. To distinguish efflux from influx in these experiments, we bathed the retinae in Ringer's in which the normal $^{40}CaCl_2$ was replaced by $^{44}CaCl_2$. In darkness, the ^{40}Ca concentration (●) of the rod outer segment slowly decreased and the ^{44}Ca content (◆) slowly increased. These results suggest that, in the dark, ^{44}Ca in the Ringer's slowly exchanges with ^{40}Ca inside the rod. As, however, the decrease in ^{40}Ca appears not to be entirely compensated by the increase in ^{44}Ca, some Ca may also be lost from the rods, perhaps through a gradual deterioration of our isolated retina preparation.

In continuous dim light (68 rhodopsins bleached (Rh*) per rod per s), the rate of decrease of ^{40}Ca was about three times greater than in the dark. After subtracting the 'dark efflux', the light-induced efflux at this intensity was calculated to be $\sim8.1\times10^5$ Ca atoms per rod per s, or $\sim10^4$ Ca atoms per Rh*; this is in close agreement with the value of the light-induced increase in extracellular Ca measured in toad retina using calcium electrodes[18]. As the light intensity was increased, the rate of ^{40}Ca efflux increased. At the brightest intensity we used (10^6 Rh* per rod per s), the efflux was at least 3×10^7 Ca atoms per rod per s. This is 100 times larger than the efflux in darkness.

We could detect no effect of light on the rate of Ca influx. The rate of ^{44}Ca uptake in steady illumination (Fig. 4, ◇) was indistinguishable from that in darkness within the error of the measurements. The change in total Ca concentration in the light can therefore be obtained directly from the data in Fig. 4 by adding the curve for the ^{44}Ca increase (◇) to that for the ^{40}Ca decrease at each of the light intensities. These calculations show that light causes a decrease in the total Ca concentration. In

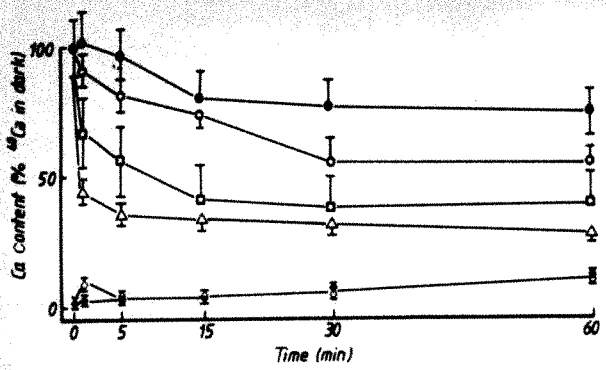

Fig. 4 Effect of light on the Ca content of the rod outer segment. The bars represent 1 s.d. Each symbol represents a different isotope or experimental condition: ●, ^{40}Ca–dark; ◆, ^{44}Ca–dark. The light intensities used for ^{40}Ca were: 68 Rh* per rod per s ○, 8.1×10^3 Rh* per rod per s □ and 10^6 Rh* per rod per s △; and for ^{44}Ca: 10^6 Rh* per rod per s ◇. Illumination was continuous.
Methods: The retina, attached to a Millipore filter, was cut into eight wedge-shaped pieces. One piece was processed immediately as a control. The other pieces were fixed to plates of dental wax with insect pins and placed in 35-mm Petri dishes containing oxygenated Ringer's of the following composition (in mmol l^{-1}): 106 NaCl, 2.5 KCl, 0.13 $NaHCO_3$, 1.5 $MgCl_2$, 1.8 $^{44}CaCl_2$, 5.6 glucose, and 3.0 HEPES at *p*H 7.8. $^{44}CaCl_2$ was taken from a stock solution prepared by dissolving $^{44}CaCO_2$ (99% pure; Rohstoffeinfuhr, Dusseldorf, FRG) in HCl. The data point at time zero is a control value determined from all retinas used in this figure, expressed as 100%. Other data points give the mean Ca content expressed as a percentage of the control at 1, 5, 15, 30 and 60 min, in each of the experimental conditions. The mean Ca content was calculated from 40 outer segments: 10 measurements were made for each of four pieces of tissue, each from a different retina. The light stimulus was a continuous 503-nm field ~50 nm in diameter. Intensity within the field was uniform within ±10%. Absolute values of intensities were measured and numbers of rhodopsins bleached calculated as described in ref. 22.

bright light, one-half to two-thirds of the total Ca in the outer segment disappeared within a few minutes. The remaining one-third to one-half appeared to be unaffected by illumination for as long as our measurements were continued.

The results presented here show that rods in the intact retina contain large amounts of Ca within their outer segments. In the dark, Ca in the rod exchanges slowly with Ca in the external medium. As the permeability of the plasma membrane to Ca seems not to be limiting (W.H.S. and G.L.F., in preparation), the slow rate of exchange may indicate that Ca is sequestered within an intracellular compartment, perhaps the disks. Exposure to light causes as much as half of this Ca to be released, most to be transported out of the rod apparently by Na–Ca exchange[18,19]. However, as much as 5% of the Ca released from the outer segment accumulates within the mitochondria of the inner segment[19], suggesting that light increases the free Ca concentration within the rod. Our results are therefore consistent with the principal postulates of the Ca hypothesis[1]. In addition, our results show that once Ca has left the rod, it is not replaced as long as illumination continues. It will be of interest to examine how the Ca content is restored once the light is extinguished, and to investigate the relationship, if any, between the re-uptake of Ca and the return of photoreceptor sensitivity during dark adaptation.

We thank M. L. Woodruff for his help at the beginning of these experiments; A. Einerhand and J. Lauer for technical assistance; E. Torres and H. Erkens for assistance in constructing the photostimulator; D. Schröder and E. Mason for typing the manuscript; H. Kühn and H. Stieve for much useful advice and criticism; H. Stieve, H. Kühn and J. E. Lisman for reading an earlier draft of the manuscript; and H. Stieve and the staff of the Kernforschungsanlage for their hospitality, without which these experiments would not have been possible. This research was supported in part by a SFB grant 160 to W.H.S. and by NIH grants EY 01844 and EY 00331 to G.L.F. W.H.S. is a Research to Prevent Blindness International Research Scholar.

ATP-stimulated interaction between epidermal growth factor receptor and supercoiled DNA

B. Mroczkowski, G. Mosig & S. Cohen

Departments of Biochemistry and Molecular Biology, Vanderbilt University, Nashville, Tennessee 37232, USA

The receptor for epidermal growth factor (EGF) has been identified as a transmembrane glycoprotein that has tyrosine-specific kinase activity[1]. The kinase activity of the receptor is enhanced in the presence of EGF (or related peptides), and the phosphorylation of a number of substrates, as well as autophosphorylation of the receptor, has been reported[1]. Analogous findings have been described for the insulin receptor and the receptor for platelet-derived growth factor (PDGF)[2]. Thus, a number of hormone receptors and several viral transforming proteins[3] appear to share the highly unusual property of tyrosine-specific kinase activity. Nevertheless, the specific relationship between tyrosine kinase activity and the control of cell growth and replication is unknown. It is known that after the initial binding of EGF to the plasma membrane, the hormone together with its receptor is rapidly internalized in endocytic vesicles and the hormone is eventually degraded in lysosomes[4]. It is possible that the function of EGF is simply to stimulate internalization of its receptor, and that as a result of its altered location the receptor is able to phosphorylate a cytoplasmic component or even interact directly with a nuclear component. We now report that the purified receptor for EGF is able to interact with and nick supercoiled double-stranded DNA in an ATP-stimulated manner.

The receptor for EGF was isolated from membrane vesicles of A-431 cells[5]. The final purification steps involved EGF-Affi Gel chromatography, wheat germ lectin–Sepharose chromatography and DNA cellulose chromatography. Figure 1*c* displays a silver stained 10% SDS-polyacrylamide gel of purified 150,000–170,000 molecular weight (MW) (lane 1) and 150,000 MW (lane 2) receptor preparations isolated from A-431 cells. Incubation of the EGF receptor with supercoiled pBR322 plasmid DNA converts form I DNA (supercoiled) to form II DNA. This conversion is ATP-dependent. Assays of equivalent aliquots from each step in this purification are shown in Fig. 1*a*. Both the kinase activity and the DNA nicking activity co-purify during the EGF-Affi Gel, wheat germ lectin–Sepharose and DNA cellulose purification steps. The purified EGF receptor also reacts with partially relaxed topoisomers of pBR322

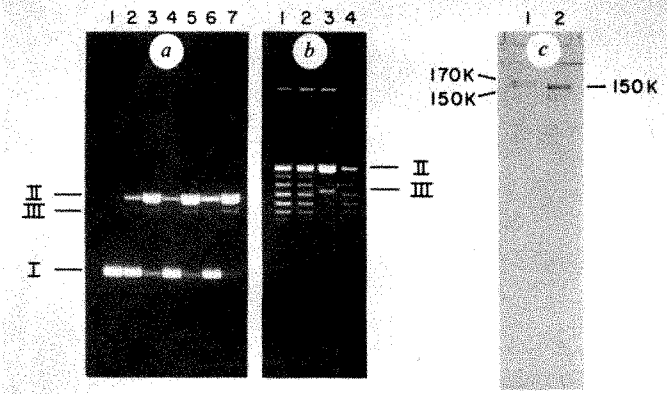

Fig. 1 Agarose gel electrophoresis of pBR322 plasmid DNA after incubation with the EGF receptor in the presence or absence of ATP. *a*, Interaction of supercoiled pBR322 DNA (form I) with various preparations of the EGF receptor. Lane 1, 0.8 μg of form I DNA; lanes 2 and 3, 0.8 μg of form I DNA incubated with wheat germ lectin purified EGF receptor in the absence (lane 2) or presence (lane 3) of 5 mM ATP; lanes 4 and 5, 0.8 μg of form I DNA incubated with wheat germ lectin purified EGF receptor passed through single-stranded DNA agarose in the absence (lane 4) or presence (lane 5) of 5 mM ATP; lanes 6 and 7, 0.8 μg of form I DNA incubated with wheat germ lectin purified EGF receptor passed through double-stranded DNA cellulose in the absence (lane 6) or presence (lane 7) of 5 mM ATP. *b*, Interaction of partially relaxed preparations of pBR322 (topoisomerase I-treated pBR322 DNA) with the EGF receptor. Lane 1, 0.8 μg of enzymatically relaxed pBR322 DNA; lanes 2–4, 0.8 μg of relaxed pBR322 DNA incubated with the EGF receptor in the absence of ATP (lane 2), the presence of 5 mM ATP (lane 3), or the presence of 5 mM AMP (lane 4). *c*, Silver stained 10% SDS-polyacrylamide gel of the 170,000/150,000 MW (lane 1) and 150,000 MW (lane 2) EGF receptor preparations purified by EGF Affi-Gel, wheat germ lectin–Sepharose and DNA-cellulose chromatography.

Methods: Agarose gel electrophoresis was performed in 40 mM Tris-acetate, *p*H 7.9, 20 mM sodium acetate at room temperature for 12 h at 3 V cm^{-1}. The 0.8% agarose gel (*a*) and 1.0% agarose gel (*b*) were stained with ethidium bromide and photographed with UV illumination. The preparation of A-431 membrane vesicles and subsequent EGF Affi-Gel purification of the EGF receptor has been described elsewhere[5]. The EGF Affi-Gel purified receptor was adsorbed to a wheat germ lectin–Sepharose column and the receptor was eluted with 3 mM *N*, *N'*, *N''*,-triacetylchitotriose essentially as described for the mouse liver EGF receptor[6]. DNA-cellulose (P-L Biochemicals) chromatography and single-stranded DNA agarose (BRL) chromatography of the wheat germ lectin purified receptor were performed in buffer comprising 0.2% Triton, 10% glycerol, 20 mM HEPES, *p*H 7.4 and 2 mM $MgCl_2$. Approximately one bed volume of wheat germ lectin purified receptor was added to the DNA matrix and adsorption was allowed to take place 30 min on ice with stirring. The receptor preparation did not bind to either matrix. (These DNA columns were used in an attempt to remove any trace nuclease contamination.) The conversion of supercoiled (form I DNA) to nicked DNA (form II DNA) was carried out in 20 mM HEPES, *p*H 7.4, 5 mM $MgCl_2$ and 5 mM ATP in a reaction volume of 30 μl. The reaction was terminated either by the addition of SDS (2%) or by phenol extraction followed by ethanol precipitation. The amount of purified receptor added per reaction mixture varied from 0.2 μg to 0.8 μg. The conversion of form I DNA to form II DNA, however, can be detected with as little as 0.02 μg of purified receptor. In all the experiments described here, incubation was allowed to proceed for 25 min at room temperature and unless specified otherwise the receptor preparation was purified by both wheat germ lectin–Sepharose chromatography and single-stranded DNA agarose chromatography. pBR322 plasmid DNA (derived from *Escherichia coli* strain NH 7007) was purified by Sephacryl S-1000 chromatography followed by caesium chloride buoyant density centrifugation[8]. Wheat germ topoisomerase I (Promega Biotec) was used to partially relax supercoiled pBR322 DNA.

(topoisomerase I-treated preparations of pBR322 DNA) in the presence of ATP to yield form II DNA (Fig. 1*b*). This conversion does not occur when AMP is substituted for ATP (Fig. 1*b*, lane 4).

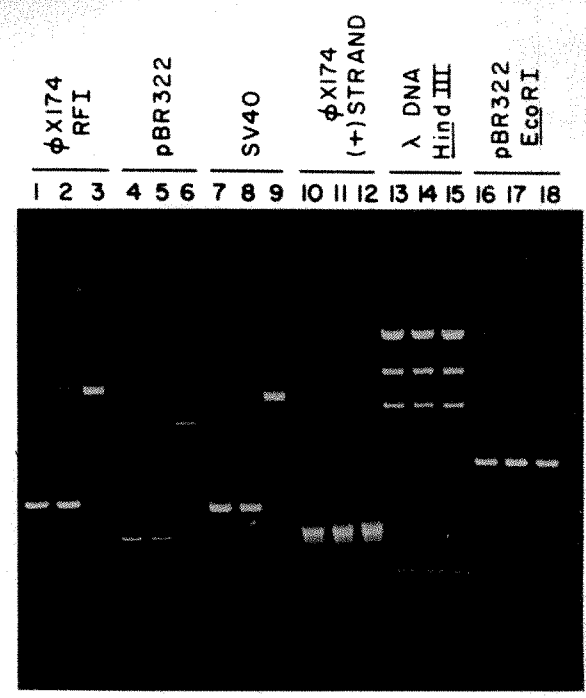

Fig. 2 Specificity of the EGF receptor–DNA interaction. Purified EGF receptor was incubated with different DNA templates in the presence or absence of ATP and the DNA products were analysed by agarose gel electrophoresis. Lanes 1–3, ΦX174 RFI DNA (0.75 μg) was incubated in the absence of the EGF receptor (lane 1), or in the presence of EGF receptor without (lane 2) or with (lane 3) 5 mM ATP; lanes 4–6, plasmid pBR322 DNA (0.3 μg) incubated in the absence of the EGF receptor (lane 4), or in the presence of EGF receptor without (lane 5) or with (lane 6) ATP; lanes 7–9, supercoiled SV40 DNA (0.9 μg) incubated in the absence of receptor (lane 7) or in the presence of receptor without (lane 8) or with (lane 9) ATP; lanes 10–12, ΦX174 single-stranded (+) DNA incubated in the absence of receptor (lane 10), or in the presence of receptor without (lane 11) or with (lane 12) ATP; lanes 13–15, a *Hin*dIII digest of DNA (1.8 μg) incubated in the absence of receptor (lane 13) or in the presence of receptor without (lane 14) or with (lane 15) ATP; lanes 16–18, *Eco*RI digest of pBR322 (0.6 μg) incubated in the absence of receptor (lane 16) or in the presence of receptor without (lane 17) or with (lane 18) ATP. Where indicated, the DNA was digested to completion by the appropriate restriction enzyme (New England Biolabs), phenol extracted and ethanol precipitated prior to addition to the reaction mixture. The DNA products were fractionated on a 1% agarose gel.

The ATP-dependent conversion of supercoiled (form I) pBR322 to form II is observed when either the 170,000/150,000 MW receptor preparations or the 150,000 MW proteolytic cleavage product of the native 170,000 MW A-431 EGF receptor is utilized in the reaction mixture. Both the 170,000 MW and the 150,000 MW forms of the receptor have been shown to possess binding activity for EGF and EGF-stimulated tyrosine-specific kinase activity[5]. The 170,000 MW EGF receptor isolated from normal mouse liver[6] also possesses the ATP-dependent nicking activity for form I pBR322 DNA (data not shown). It is of interest that in these assay conditions the activity is not significantly altered by the addition of EGF to the reaction mixture; in contrast, EGF enhances the tyrosine kinase activity of the receptor[5].

The specificity of the interaction of the EGF receptor with DNA was examined by incubating the EGF receptor, in the presence or absence of ATP, with a variety of nucleic acid substrates and examining the reaction products by agarose gel electrophoresis.

As illustrated in Fig. 2, the conversion of form I plasmid DNA to form II DNA is not specific for pBR322; ΦX174 RFI DNA (Fig. 2, lanes 1–3), simian virus 40 (SV40) DNA (Fig. 2, lanes 7–9), and PM2 DNA (data not shown) react in a fashion similar to pBR322 DNA (Fig. 2, lanes 4–6). Regardless of the

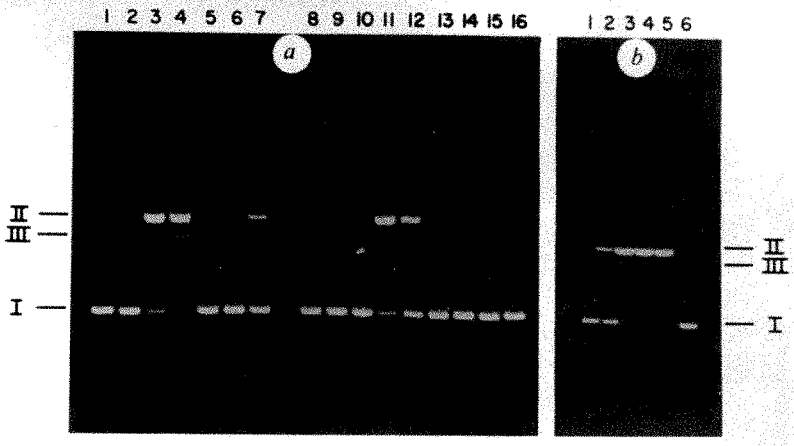

Fig. 3 Nucleotide preference and heat stability of the EGF receptor-associated DNA-relaxing activity. ***a***, Plasmid pBR322 was incubated with the EGF receptor in standard assay conditions (see Fig. 1) in the presence of various nucleotides. Lanes 1 and 8, pBR322 DNA (0.8 μg) incubated without EGF receptor; lanes 2–16, pBR322 DNA (0.8 μg) incubated with the EGF receptor in the absence of nucleotide (lanes 2 and 9) or with 5 mM ATP (lane 3), 5 mM dATP (lane 4), 5 mM 5′-AMP-PNP (lane 5), 5 mM dAMP (lane 6), 5 mM ADP (lane 7), 5 mM TTP (lane 10), 5 mM CTP (lane 11), 5 mM UTP (lane 12), 5 mM GTP (lane 13), 20 mM GTP (lane 14), 5 mM dGTP (lane 15), and 20 mM dGTP (lane 16). ***b***, Heat inactivation of the DNA-relaxing activity of the EGF receptor. Receptor preparations were heated in a water bath at the indicated temperature before addition to the reaction mixture. Lane 1, pBR322 DNA (0.8 μg) incubated in reaction mixture plus ATP but minus the EGF receptor; lane 2, pBR322 DNA incubated with the EGF receptor but minus ATP; lane 3, pBR322 DNA incubated in the presence of both ATP and the EGF receptor; lanes 4–6, pBR322 DNA incubated with ATP and the EGF receptor that had been heated for 15 min at 45 °C (lane 4), 15 min at 65 °C (lane 5), and 5 min at 90 °C (lane 6) before addition to the reaction mixture. Reaction products were fractionated by electrophoresis in 0.8% agarose and stained with ethidium bromide.

source of the closed duplex DNA a small amount of linearized product (form III DNA) is always detected in the presence of ATP and the EGF receptor. In control experiments neither linearized pBR322 (Fig. 2, lanes 16–18) nor a *Hin*dIII digest of DNA (Fig. 2, lanes 13–15) appeared to be affected by incubation with the EGF receptor in the presence of ATP. Furthermore, using nick-translated ^{32}P-labelled rabbit pox virus DNA or uniformly ^{3}H-labelled total cellular RNA from vesicular stomatitis virus (VSV) infected cells as substrates we could detect only a trace of nuclease activity (trichloroacetic acid soluble radioactivity) with the former substrate (<0.5% digestion) and none with the ^{3}H-labelled RNA after incubation for 3 h at room temperature in the presence of the EGF receptor and ATP. Thus appreciable enzymatic digestion of these nucleic acids was not detected.

Although the data suggest that the observed activity is intrinsic to or tightly associated with the receptor, we cannot unequivocally rule out the possibility that what we are observing is a low level of ATP-dependent, lectin-adsorbable endonucleolytic contamination which is observed solely in a highly sensitive assay such as the conversion of form I DNA to form II DNA, and which is present in both forms of the EGF receptor prepared from A-431 cells and the receptor prepared from mouse liver. However, no nicking activity was detected when highly purified preparations of tubulin, bovine serum albumin, IgG, EGF or PDGF were assayed.

Some of the biochemical properties associated with the DNA-nicking activity of the EGF receptor are depicted in Fig. 3. Figure 3*a* demonstrates that both UTP and CTP as well as dATP can substitute for ATP in the reaction mixture. However, the non-hydrolysable analogue of ATP, 5′-AMP-PNP, is not capable of replacing ATP, nor are GTP, dGTP, or TTP effective. The optimum ATP concentration for this reaction is 2–7 mM (data not shown). The activity is extremely heat stable (Fig. 3*b*), withstanding incubation at a temperature of 65 °C for 15 min and requiring incubation at 90 °C for at least 5 min for complete loss of activity. This thermal inactivation profile is profoundly different from that observed for the tyrosine kinase activity intrinsic to the EGF receptor. Over 80% of the tyrosine kinase activity of the EGF receptor is inactivated by heating for 15 min at 45 °C, while the EGF binding activity of the EGF receptor requires heating for 15 min at 65 °C for inactivation[7]. The observed ATP-dependent DNA reaction appears to have a *p*H optimum of 6.8–7.6 and is drastically inhibited by relatively low salt concentrations (100 mM KCl or NaCl).

To ascertain whether the reaction products are nicked or whether they represent relaxed, covalently closed circular DNA, agarose gel electrophoresis was performed in the presence or absence of ethidium bromide. In the presence of ethidium bromide the relative migration of a relaxed species of plasmid

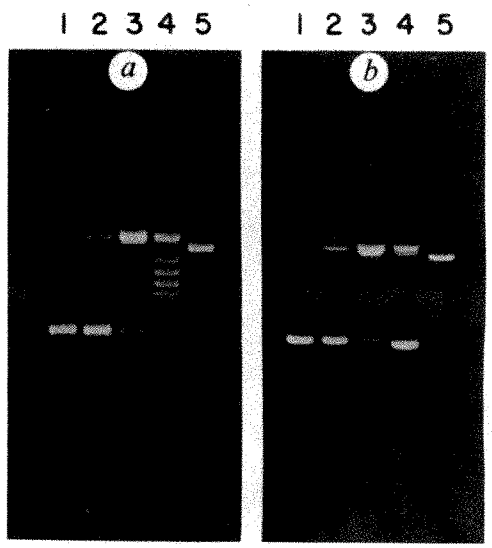

Fig. 4 Comparison of electrophoretic mobilities of pBR322 DNA reaction products in the presence or absence of ethidium bromide. ***a***, Agarose gel electrophoresis in the absence of ethidium bromide. Lanes 1–3, pBR322 DNA (0.4 μg) incubated in the absence of EGF receptor (lane 1), in the presence of EGF receptor without ATP (lane 2), or in the presence of EGF receptor plus ATP (lane 3); lane 4, pBR322 DNA (0.6 μg) enzymatically relaxed with wheat germ type I topoisomerase; lane 5, pBR322 DNA treated with *Eco*RI. 0.7% agarose gel was electrophoresed in 40 mM Tris-acetate, *p*H 7.9, 20 mM sodium acetate at room temperature for 12 h at 3 V cm^{-1}. ***b***, Agarose gel electrophoresis run exactly as in *a*, except for the inclusion of ethidium bromide (0.5 μg ml^{-1}) in both the gel matrix and running buffer. Aliquots of reaction mixtures described in *a* were brought to a final concentration of 0.5 μg ml^{-1} of ethidium bromide before electrophoresis. Lane 1, 0.4 μg of pBR322; lane 2, 0.4 μg of pBR322 incubated in the presence of EGF receptor minus ATP; lane 3, 0.4 μg of pBR322 incubated in the presence of EGF receptor and 5 mM ATP; lane 4, 0.6 μg pBR322 enzymatically relaxed with wheat germ type I topoisomerase; lane 5, *Eco*RI-treated pBR322. Electrophoresis was performed in the dark to minimize nicking of the DNA.

DNA should change as the molecule progressively binds more ethidium bromide to become increasingly positively supercoiled (compare lanes 4 in Fig. 4*a* and *b*) while that of a nicked species should not change in the presence of the intercalating dye. Comparison of lanes 3 in Fig. 4*a* and *b* indicates that the reaction product generated in our conditions in the presence of both ATP and the EGF receptor represents a nicked form of plasmid DNA since the relative mobility of form II DNA is not affected by the presence of ethidium bromide.

In view of the biological implications of the observations, and the association of tyrosine kinase activity with both the EGF receptor and pp60^{src}, we have examined three preparations of pp60^{src}. All three preparations generated reaction products apparently identical to those generated by the EGF receptor in the same conditions (data not shown). The DNA-nicking activity of pp60^{src} is also dependent on ATP.

In a number of isolated cases we have observed the generation of a high molecular weight DNA species (possibly representing concatenated DNA) exclusively in the presence of ATP and the EGF receptor. The generation of relaxed topoisomers from covalently closed supercoiled DNA in the presence of pp60^{src} has also occasionally been observed. It is possible that the enzymatic activity reported here is both a nicking and a closing activity reminiscent of other DNA interacting proteins such as DNA topoisomerases. Final proof that this activity is intrinsic to both the EGF receptor kinase and pp60^{src} is not yet available. However the association of DNA-nicking activity with tyrosine kinase preparations from diverse sources is intriguing. A nuclear translocation of these membrane-associated proteins, perhaps via endocytic vesicles and subsequent interaction with DNA could conceivably be responsible for some of the pleiotropic responses accompanying growth stimulation.

We thank Drs R. Erikson and J. Brugge for their gifts of pp60^{src}, Drs S. and R. Moyer for the labelled nucleic acid substrates, and Marty Reich and Katherine Chen for technical assistance. Activation of cellular gene by mouse mammary tumour virus may occur early in mammary tumour development

Gordon Peters, Audrey E. Lee & Clive Dickson

Imperial Cancer Research Fund Laboratories, PO Box 123, Lincoln's Inn Fields, London WC2A 3PX, UK

There is now good evidence that the induction of mammary carcinomas by mouse mammary tumour virus (MMTV) involves provirus activation of specific cellular genes. Thus, a high percentage of virally induced tumours contain an acquired MMTV provirus in either of two defined integration regions, termed *int-1* and *int-2*, and provirus insertion is accompanied by expression of specific RNA transcripts from these regions[1–4]. We show here that in some recurring, pregnancy-dependent mammary tumours provirus integration within *int-2* has already occurred at the earliest appearance of the tumour and may therefore represent an important step in the development of neoplasia. As judged by the distribution of the acquired MMTV proviruses, the tumours recurring at any one site represent the same clonal population of cells as the original tumour and remain clonal during cycles of proliferation and regression, including the transition to hormone-independent status. These data suggest that either the expression of the *int-2* locus or the function of this putative oncogene must remain responsive to hormones and that some additional event must be responsible for the transition to autonomous growth.

Although MMTV is one of the principal causative agents in the development of mouse mammary tumours, the incidence and progression of the disease is multifactorial, being influenced by such parameters as genetic background, parity and hormonal status of infected animals[5,6]. In BR6 mice, which suffer a mammary tumour incidence of over 90% as a result of milk-borne MMTV[7], tumours develop to a detectable size only after an average of four pregnancies and ~70% of them are initially hormone-dependent in that they regress completely or partially between pregnancies[8,9]. In subsequent pregnancies, the tumour becomes re-established at the same site but eventually progresses to become autonomous and to grow independently of the hormonal status of the animal.

Female BR6 mice were examined at each pregnancy for the presence of detectable tumours and, where possible, surgical biopsies were taken amounting to ~50% of the tumour mass. The aim was to collect repeated biopsies from the same site at each recurrence as the tumour progressed from a hormone-dependent to independent phenotype. As illustrated in Fig. 1, the number of pregnancies required to establish hormone independence was variable, ranging in the examples studied from two at tumour site B to at least six at tumour site A. Figure 1*d* includes an example of a tumour series from which no biopsies were taken, in order to illustrate the more typical pattern not distorted by the surgical removal of tissue.

DNA of high molecular weight was prepared from each fresh biopsy and analysed by Southern blotting procedures using MMTV-specific probes (see Fig. 2 legend for details). As shown in Fig. 2*b*, normal tissues in the BR6 mouse (track N) contain three endogenous proviral units of MMTV. Such endogenous sequences are present in all tissues and on both chromosomes, whereas newly acquired MMTV proviruses occur on only one of any pair of chromosomes. Thus, in a truly clonal population of infected cells, the intensity of the hybridization signal from an acquired provirus should be half that of an endogenous unit. In practice, the quantitation can be distorted by the inclusion of any normal tissue in the tumour biopsy, but the data presented here, and in many other studies[1,2,10–13], indicate that mammary tumours approach this idealized clonal situation. In all the pregnancy-dependent series examined at least one pair of novel junction fragments was present in DNA from the first biopsy, indicating that acquisition of additional MMTV sequences is probably an early event in tumour induction. Moreover, identically sized, novel fragments were detectable in all subsequent biopsies from the same site, suggesting that recurrence of the tumour at each pregnancy results from expansion of the same, clonal population of tumorigenic cells.

Although the initial pattern of acquired MMTV proviruses remained stable during subsequent cycles of proliferation and regression, DNA from the later biopsies occasionally showed a more complicated pattern (for example tumour sites B and C in Fig. 2). Since the changes were invariably additive, and were not accompanied by loss or rearrangement of established proviruses, they presumably resulted from superinfection of the tumour tissue by MMTV. Judging from the intensities of these additional junction fragments on the autoradiograph, superinfection must have occurred either before or very early in a period of proliferation such that a high percentage of tumour cells contained the same fragments. Since most of the cells in a tumour nodule are presumably lost during regression, each recurrence of the nodule must originate from perhaps a single or, at most, a small number of tumorigenic cells and will therefore only reflect the proviral pattern in this or these cells. It is possible that these represent a stem cell population whose capacity to differentiate in response to the hormonal influences accompanying pregnancy remains unimpaired after infection and possibly 'transformation' by MMTV.

At this stage, we cannot formally exclude the possibility that the acquisition of additional MMTV sequences may have contributed to the transition of tumours to autonomous growth. However, since examples have been found in which hormone independence was apparently achieved without further provirus

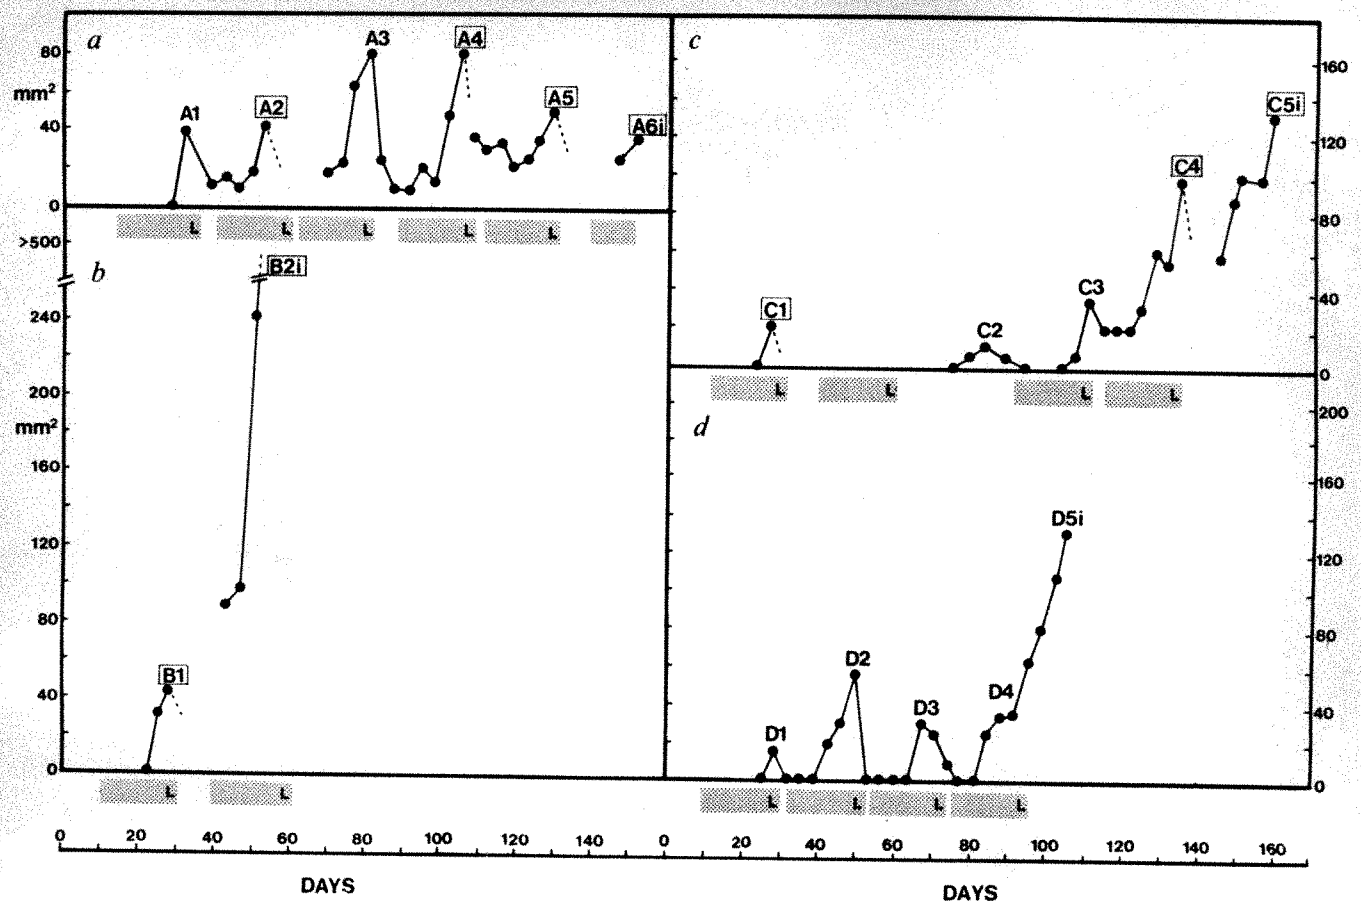

Fig. 1 Cycles of pregnancy-dependent tumour growth and regression. Female BR6 mice were routinely examined for palpable mammary tumours and the progression of each tumour during cycles of pregnancy was monitored. *a–d*, Four independent sites (A–D) at which recurrent tumours arose in four separate mice. The shaded bars below the abscissa of each panel indicate the observed periods of pregnancy, with L signifying delivery of a litter. Size measurements were taken twice weekly, and are expressed on the ordinate as mm^2, representing the product of two orthogonal diameters[8]. Boxed letters and numbers refer to the site and cycle of growth at which surgical biopsies, amounting to ~50% of the tumour mass, were removed for histological examination[9] and DNA extraction[2]. No biopsies were taken from site D in order to display a more typical pattern of tumour growth and regression. The symbol i indicates the cycle or biopsy at which the tumour was judged to have become hormone-independent. We are not certain that the tumour designated A6i had fully progressed to hormone independence since the presence of other independent tumours in the same mouse necessitated death at this point.

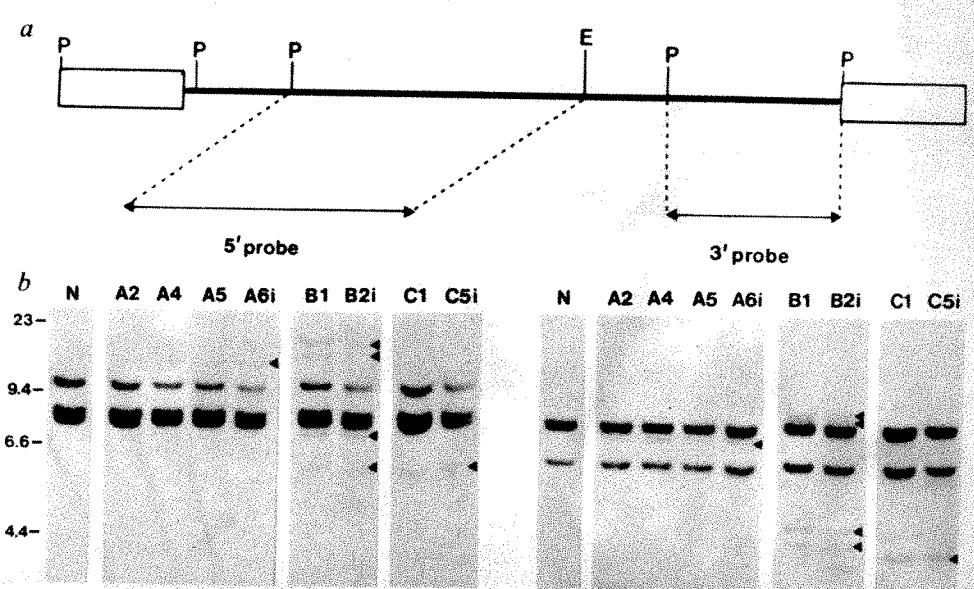

Fig. 2 Analysis of MMTV proviral units in recurring, pregnancy-dependent mammary tumours. *a*, A restriction map of the GR strain of MMTV provirus is depicted showing the sites of cleavage for the enzymes *Eco*RI (E) and *Pst*I (P)[10]. Digestion of cellular DNA with *Eco*RI generates two virus–cell junction fragments distinguishable by hybridization with the cloned 5′-specific and 3′-specific fragments as indicated[2]. *b*, DNA of high molecular weight was prepared[2] from freshly dissected biopsies of mammary tumours which recurred at three independent sites (A, B and C) in three different animals (see Fig. 1). The numbers refer to cycles of tumour growth, with i signifying the final, hormone-independent tumour. N represents the normal tissue control, in this case the spleen taken from the same animal as the A series of tumours. Samples of DNA (10 μg) were digested with an excess of *Eco*RI, fractionated on 0.8% agarose gels and transferred onto nitrocellulose filters as described previously[2]. The filters were then hybridized for 36–48 h with either the 5′ or 3′ specific fragment of viral DNA, labelled with ^{32}P-dCTP by nick-translation. Before autoradiography the filters were washed in 0.1 × SSC/0.1% SDS at 65 °C[2]. The sizes of the various virus–cell junctions detected in this way were estimated relative to fragments of λ DNA generated by digestion with *Hin*dIII (shown in kilobases on the left of the panel). Normal tissues from BR6 mice contain three endogeneous units of MMTV, characterized by 5′ junction fragments of 7.7, 7.9 and 9.6 kb, while the 3′-specific junctions appear as a 6.2 kb band and a 7.6 kb doublet. The positions of novel fragments corresponding to acquired MMTV proviruses are indicated (◄).

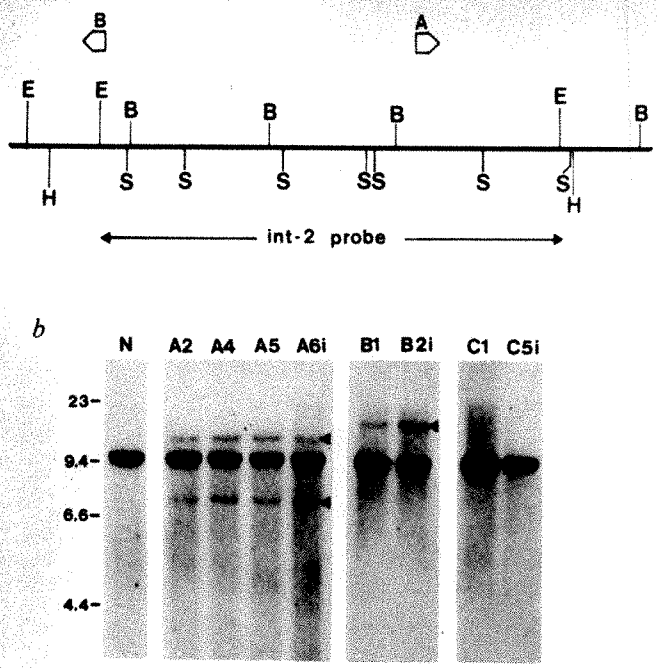

Fig. 3 Provirus insertion in the *int-2* locus in pregnancy-dependent mammary tumours. *a*, The restriction map of the MMTV *int-2* locus in BALB/c DNA indicates the sites of cleavage for the enzymes *Eco*RI (E), *Hin*dIII (H), *Bam*HI (B) and *Sac*I (S). The identification and characterization of this locus, and the derivation of the 10.0 kb *Eco*RI fragment used as a probe, have been presented elsewhere[2,4]. Using these enzymes, no restriction site polymorphisms were detected in the relevant DNAs from BALB/c and BR6 mice. The arrow symbols above the map indicate sites and orientation of integrated proviruses as discussed below. *b*, The nitrocellulose filter carrying the DNA samples analysed with the 3′-specific viral probe in Fig. 2*b* was rinsed in alkali to remove residual probe and then hybridized with the 10.0 kb *int-2* probe indicated. Conditions and symbols are as described in the legend to Fig. 2. N represents a sample of normal tissue DNA, in this case the spleen, showing the homologous uninterrupted 10.0 kb *Eco*RI fragment detected with this probe. The sizes of any novel fragments generated by provirus insertion (identified by the symbol ◄) were estimated relative to *Hin*dIII digested λ DNA standards as shown. From these data, it was possible to deduce both the site and transcriptional orientation of the provirus integrated within *int-2* in both the A and B tumour series. As indicated in *a*, these two proviruses map about 6-7 kb apart in the cellular DNA and are in opposite transcriptional orientations. In the C series of tumours, no provirus insertions were detected in over 30 kb of DNA centred on the *int-2* locus.

integration (as at tumour site A), we would argue that the acquisition of further proviral elements during progression of the tumour probably reflects fortuitous superinfection and does not contribute to the phenotypic change.

We have previously identified a region of DNA on mouse chromosome 7, *int-2*, in which an MMTV provirus has integrated in ~50% of all BR6 mammary tumours examined whether hormone-dependent or independent[2,4,14]. As we were interested in determining the status of this locus in the pregnancy-dependent tumour series, the nitrocellulose filters used in preparing Fig. 2 were rehybridized with a probe corresponding to the 10.0 kilobase (kb) *Eco*RI fragment from *int-2* (ref. 2). As indicated in Fig. 3, both the A and B tumour series showed evidence for provirus integration within this fragment. The simplest example is provided by the A series in which two novel *Eco*RI fragments were detected in addition to the normal 10.0 kb fragment present on the uninterrupted chromosome. The larger of these novel fragments was identical in size (~12.5 kb) to the virus–cell junction detected with a 5′-specific viral probe (Fig. 2*b*); while the smaller (~7.4 kb) coincided with the corresponding 3′-specific junction. These data are therefore consistent with integration of a complete MMTV provirus at the position, and in the transcriptional orientation, indicated on the restriction map in Fig. 3. With the site B tumours only one novel fragment was detected in these analyses, corresponding in size to one of the 5′-specific junctions observed in Fig. 2*b*. The provirus integration site therefore mapped very close to the 5′ boundary of the 10.0 kb *Eco*RI fragment, and in the orientation shown (Fig. 3*a*), such that the 3′-specific junction had only a very short region of overlap with the probe. This interpretation has been verified by preparing Southern blots with each of the different restriction endonucleases whose sites are depicted in Fig. 3*a* (data not shown).

Two significant conclusions can be drawn from these observations. First, the A and B tumour series are clonal, in that the same provirus, integrated within *int-2*, remains detectable and unaltered during cycles of pregnancy-dependent growth and regression and in the transition to hormone independence. The second is that since integration within *int-2* apparently occurs by the earliest appearance of the tumour, it may represent an important step in the development of neoplasia. This latter conclusion is supported by data to be presented elsewhere which indicate that polyadenylated RNA transcripts derived from the *int-2* locus are present specifically in tumours which have sustained a provirus integration in *int-2*. Our present interpretation is therefore that MMTV-induced carcinogenesis involves proviral activation of specific cellular genes and that *int-2* represents one such gene.

The observations of provirus insertions in these tumours make significant predictions regarding the involvement of *int-2* in tumorigenesis. If the activation of RNA and protein synthesis from a putative oncogene within *int-2* is the primary event in the onset of neoplasia, then either the expression of this gene product or the target to which its activity is directed, must remain under hormonal control. It is not possible at this stage to determine whether this reflects the direct action of hormones on some functions of the provirus[15-18], or whether the tumour cells are simply continuing to respond normally to the hormonal fluxes accompanying pregnancy[5,19]. However, the data also imply that activation of *int-2* or other analogous loci are not sufficient for the development of frank malignancy and may therefore represent only part of a multistage process. Some additional stochastic event, such as the activation or mutation of alternative cellular genes, may be required to obviate this hormone dependence and permit the tumour to develop autonomously. Pregnancy-dependent tumours in the BR6 mouse provide a powerful system in which to dissect the roles of these various factors in mammary carcinogenesis.

We thank Ros Smith, Sharon Brookes and Len Rogers for technical assistance; Mike Hayman, Malcolm Parker and John Wyke for helpful discussions and Audrey Gibson for help in preparing the manuscript.

Long terminal repeats of human T-cell leukaemia virus II genome determine target cell specificity

Irvin S. Y. Chen, Jami McLaughlin & David W. Golde

Division of Hematology-Oncology, Department of Medicine, UCLA School of Medicine, Los Angeles, California 90024, USA

Human T-cell leukaemias and lymphomas associated with the human T-cell leukaemia viruses (HTLV)[1-3] are invariably neoplasms of cells with mature T-lymphocyte phenotype[4,5]. Epstein–Barr virus-transformed B-lymphocyte lines which are productively infected with HTLV may be isolated from patients with HTLV malignancies[6,7], but no non-lymphoid tissues seem to be involved. Here, to investigate the basis for this tissue specificity, we introduced type II HTLV (HTLV-II) into a variety of human cells by infection and also by transfection of recombinant genomes. We found no HTLV-II expression in non-lymphoid tissues although expression and correct initiation of transcription was observed in B and T lymphocytes. Our results using recombinant genomes indicate that the restriction of expression is at least partly due to *cis*-acting functions of the long terminal repeats which lie at each end of the HTLV genome.

Normal human peripheral blood T lymphocytes and Epstein–Barr virus (EBV) transformed B-lymphocyte cell lines were productively infected by HTLV-II by co-cultivation with HTLV-II-infected Mo cells[7] but attempts to infect cells of non-lymphoid origin were unsuccessful (Table 1). Epithelial/B-lymphocyte hybrid cells (D98/Raji[8] and D98/HRI[9]) were infected, as shown by the presence of HTLV-II proviral DNA in ~10% of the cells for up to 50 generations, but no viral p19 or p24 antigens were detected by indirect immunofluorescence (Table 1) and co-cultivation of infected hybrid cells with normal human peripheral blood lymphocytes did not result in HTLV-II transformation of the normal cells (data not shown).

Table 1 HTLV-II infection by co-cultivation with Mo cells

Cells	HTLV-II genome	Viral antigens p19 and p24
Peripheral blood lymphocytes	+	+
EBV-transformed B cell		
G-B	+	+
WIL-2	+	+
Primary fibroblasts		
R	NT	–
C	NT	–
K	NT	–
Fibroblast cell line (143)[8]	NT	–
Epithelial/B-lymphocyte hybrid line		
D98/RAJI[9]	+	–
D98/HRI[11]	+	–

In every case 5×10^5 cells were co-cultivated with an equal number of lethally irradiated Mo cells[7]. In the case of adherent cells, the Mo cells were washed out after 1 week of co-culture and the cells passaged for at least an additional 2 weeks before the cells were fixed for indirect immunofluorescence for viral p19 and p24 antigens and their DNA extracted for hybridization by the method of Southern[18]. In the case of nonadherent cells, the cells were co-cultured for 5–6 weeks. Most Mo cells were dead by the second week of co-culture. NT, not tested.

Since HTLV-II infection by co-cultivation is a relatively inefficient process, probably due to the low titres of infectious virus produced by infected cells, we also used DNA transfection with selectable markers to introduce HTLV-II DNA into cells. We initially tested the ability of an HTLV-II provirus (λH6,

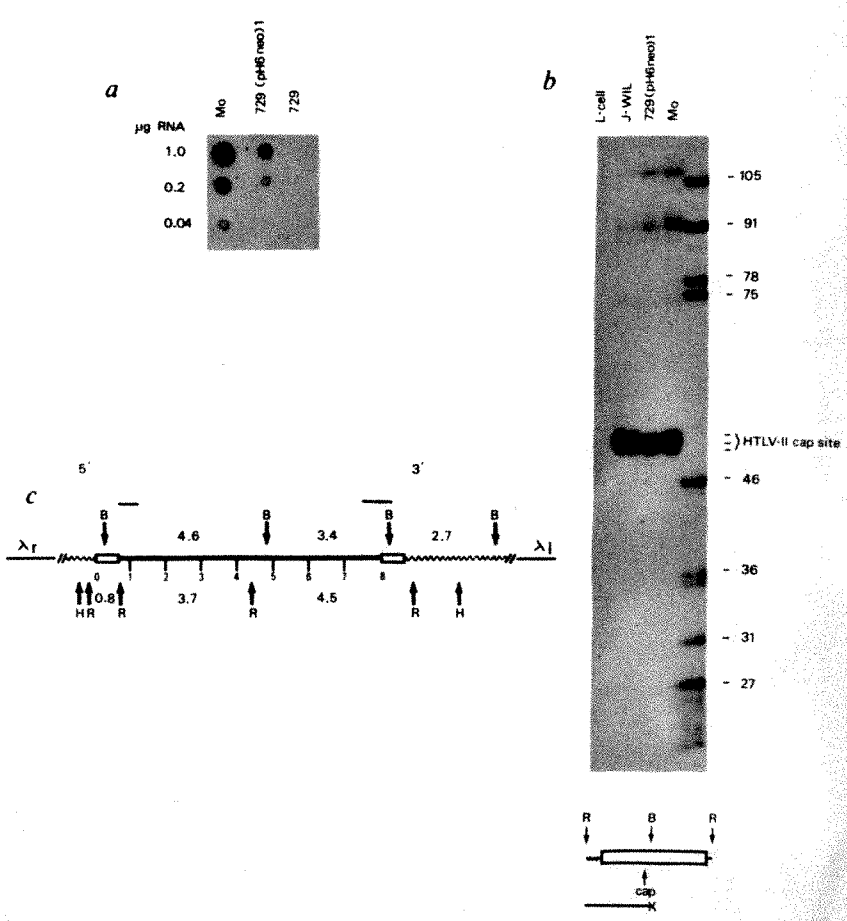

Fig. 1 HTLV-II RNA sequences in 729 B cells stably transfected with λH6 DNA. ***a***, Serial dilutions of poly(A)-containing RNA prepared from Mo cells; a clone of 729 cells transfected with pH6neo (729(pH6neo)1) and normal 729 cells. The indicated amounts of RNA were spotted onto nitrocellulose filter paper and hybridized[24]. The location of sequences in the probe is shown in *c* and are derived from cDNA clones pH-1 and pH-13[13]. The probe was purified free of pBR322 sequences so only HTLV-II-specific hybridization would be detected. ***b***, S_1 nuclease analysis[25] of total RNA from mouse L-cells; HTLV-II infected B cells (J-WIL); 729(pH6neo)1; and Mo cells. The cap site of HTLV-II (nucleotide 314 ± 1) was determined previously[20]. The position of the probe in the 5′ LTR of the λH6 provirus is indicated below the autoradiogram. The probe is 5′ end-labelled at the *Bam*HI site (nucleotide 360[20]) in the LTR. The expected sizes of the protected fragments are 50, 51 and 52 bases[20]. The size of *Sau*3A-digested pBR322 fragments are indicated. ***c***, The restriction enzyme sites *Hin*dIII (H), *Bam*HI (B) and *Eco*RI (R) in λH6 proviral DNA[13] and flanking human cellular DNA. The orientation of the provirus is indicated by 5′ and 3′ and the right and left arms of the λ1059 vector are indicated by λ_r and λ_l respectively. The numbers directly beneath the genome indicate the size in kilobases (kb). The numbers between restriction enzyme sites represent the size of HTLV-II DNA fragments. The location of HTLV-II sequences used in the hybridization probe are shown by bars indicated above the map.
Methods: 10^7 729 cells were transfected by spheroplast fusion[26] with a provirus HTLV-II subcloned in the *Eco*RI site of pSV2-neo[10] (pH6neo) and plated at 10^5 viable cells (viability was usually ~50%) per well of a 24-well culture dish. The frequency of G418-resistant cells was about 10^{-5}. Cells resistant to 750 μg ml^{-1} G418 were propagated for analysis. Details of the construction of pH6neo are available on request.

Fig. 1*c*) to function in an EBV-transformed B-cell line, 729, found to be competent for transfection by protoplast fusion. Cells were transfected with the entire provirus of λ H6 subcloned into pSV2-neo (ref. 10), a recombinant vector selectable in animal cells with the aminoglycoside antibiotic G418.

Approximately 25% of the G418-resistant clones of cells expressed HTLV p19 and p24 antigens as assayed by indirect immunofluorescence. Dot blot hybridization of RNA from one of these clones demonstrated expression of HTLV-II RNA (Fig. 1*a*) and S_1 nuclease analysis showed correct initiation from the cap site of the HTLV-II long terminal repeat (LTR) (Fig. 1*b*).

To study the restriction of HTLV-II expression in non-lymphoid cells, cells from a fibroblast cell line, 143, derived from a human osteosarcoma and competent for stable transfection[11], were transfected with λ H6 DNA. Since 143 cells are deficient in thymidine kinase, we used the co-transfection technique[12] with the herpes simplex virus thymidine kinase gene (pTK). In this way we obtained a stable 143 cell line containing the λ H6 provirus. Restriction enzyme analysis indicates that there are two HTLV-II DNA fragments in the cells, the smaller being the λ H6 provirus with no gross alterations of viral sequences (Fig. 2*a*). Other clones of 143 cells were obtained by transfection with a molecular clone of an HTLV-II provirus isolated from a transformed cell line, J-LB-II[7,13].

The 143 clone containing HTLV-II was negative for viral p19 and p24 antigens as assayed by indirect immunofluorescence. Poly(A)$^+$ RNA extracted from the cloned 143 cells did not hybridize to a HTLV-II-specific probe although hybridization could be detected in as little as 1.6 ng of RNA from HTLV-II-transformed Mo cells (Fig. 2*b*). Therefore, although the complete HTLV-II genome is present in the 143 cells, stable HTLV-II RNA is not detectable.

The lack of HTLV-II expression in several different human epithelial and fibroblast cells containing infected or transfected viral genomes indicates a tissue-specific restriction for HTLV-II transcription. Since the retrovirus LTR contains sequences important for the control of viral transcription and replication[14,15] we constructed recombinant genomes containing the HTLV-II LTR and the selectable gene *neo*^{R} from the bacterial transposable element Tn*5* used in pSV2-neo[10]. The transfection of selectable markers, the expression of which is dependent on *cis*-acting transcription signals, has been used as a simple assay for the efficiency of transcription of various viral and cellular promoters[16,17].

Four types of recombinant genomes were constructed to test the transcriptional efficiency of the HTLV-II LTR relative to the SV40 early promoter and SV40 termination sequences (Fig. 3). The first recombinant genome consisted of the *neo*^{R} gene, transcription of which would be initiated by the 5′ LTR, but termination of transcription would occur in SV40 sequences (pJH9LTRneo). The second recombinant represented the reciprocal of the first recombinant, in that the SV40 early promoter would initiate transcription of the *neo*^{R} gene and termination of transcription would occur in the 3′ LTR (pH6SVneoB). The third recombinant would initiate and terminate transcription of *neo*^{R} in the HTLV-II LTRs (pJH9LTRneoH6LTR). The fourth construct served as a control and consisted of the complete pSV2-neo plasmid inserted into the HTLV-II genome at the same position as for pH6SVneoB (pH6SVneo$^+$). Transcription of the *neo*^{R} gene would be initiated by the SV40 early promoter and terminated by SV40 sequences.

When the recombinant genomes were introduced into the Mo cells by protoplast fusion, G418-resistant cells were obtained at a frequency comparable to that of the SV40 vector, pSV2-neo (Fig. 3). No G418-resistant cells were obtained when Mo cells were fused with pBR322. In pJH9LTRneo and pJH9LTRneoH6LTR, expression of *neo*^{R} should be dependent upon the initiation of transcription by the HTLV-II LTR. Figure 4 shows an example of one Mo cell clone transfected with pJH9LTRneo. A DNA fragment containing *neo*^{R} is detected in the Mo cells by Southern hybridization[18]. The size of the fragment is consistent with the presence of the entire transcriptional

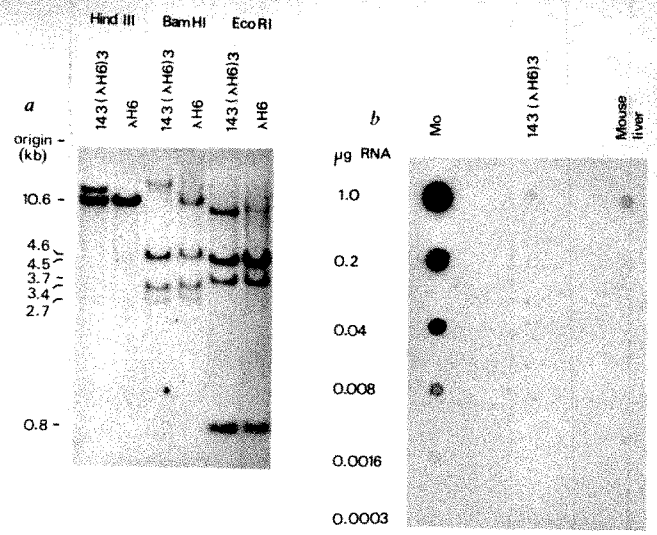

Fig. 2 HTLV-II DNA and RNA sequences in 143 cells stably transfected with λ H6 DNA. ***a***, DNA extracted from the tk$^+$ transformant 143(λ H6)3 digested with *Hin*dIII, *Bam*HI and *Eco*RI and hybridized by the method of Southern[18] using the probe shown in Fig. 1*c*[13]. λ H6 DNA is equivalent to 1.0 copy per cell mixed with 15 μg of normal human DNA and treated in parallel. As *Hin*dIII does not cleave HTLV-II sequences[13] the two fragments detected by *Hin*dIII digestion must represent two HTLV-II DNA fragments present in the cells. The smaller of the two *Hin*dIII fragments is the same size as the 10.6 kb *Hin*dIII fragment of λ H6. The larger fragment has lost several of the restriction enzyme sites of λ H6 and contains only a portion of the λ H6 provirus. The HTLV-II DNA fragments indicated in kb are those shown on the map of λ H6 in Fig. 1*c*. ***b***, Poly(A)$^+$ RNA prepared from Mo, 143(λ H6)3 and mouse liver cells and treated as described in Fig. 1*a*. Because of the long exposure of the autoradiogram, some nonspecific hybridization to mouse liver RNA is evident.

Methods: 5×10^5 tk$^-$ 143 cells[11] were co-transfected with a calcium phosphate precipitate of 0.5 μg pTK, 1 μg λ H6[13] and 20 μg ml^{-1} calf thymus DNA. Colonies of cells resistant to hypoxanthine–aminopterin–thymidine medium were cloned after 14 days and propagated.

unit of *neo*^{R} (Fig. 4*a*). In addition, protection of a 790 nucleotide DNA fragment by S_1 analysis (Fig. 4*b*) is consistent with initiation of *neo*^{R} transcription at the cap site of the HTLV-II LTR. Other Mo clones transfected with pJH9LTRneo and pJH9LTRneoH6LTR show the same 5′ ends (data not shown). Therefore, transcription of *neo*^{R} in Mo cells appears to be dependent upon HTLV-II LTR function.

Transfection into 143 fibroblast cells of pSV2-neo, where SV40 sequences are used for initiation and termination of *neo*^{R} transcription, resulted in approximately 200 colonies of G418-resistant cells per μg of plasmid (Fig. 3). However, transfection of recombinant genomes where the HTLV-II LTR was necessary for initiation of transcription (pJH9LTRneo, pJH9LTRneoH6LTR) resulted in less than 1/100th the number of colonies. The efficient transfection in 143 cells of pH6SV2neo$^+$, where expression of *neo*^{R} is dependent upon SV40 signals contained between HTLV-II LTR sequences, indicates that viral sequences are not toxic to 143 cells and are not inhibitory to uptake or stable integration of transfected DNA. Therefore, the LTR of HTLV-II appears not to promote the initiation of transcription of the *neo*^{R} gene in 143 cells effectively.

Note, in addition, that although the SV40 early promoter is functional in 143 cells when transcription is terminated in SV40 sequences (pSV2-neo), the SV40 promoter appears to be incompatible with the 3′ HTLV-II LTR when the LTR is substituted for SV40 termination sequences (Fig. 3, pH6SVneoB). In 143 cells this recombinant had a transfection efficiency that was no better than a recombinant with no termination sequences (Fig. 3, pSVneoA-). In Mo cells, pH6SVneoB had a somewhat lower efficiency of transfection than pSV2-neo but higher than

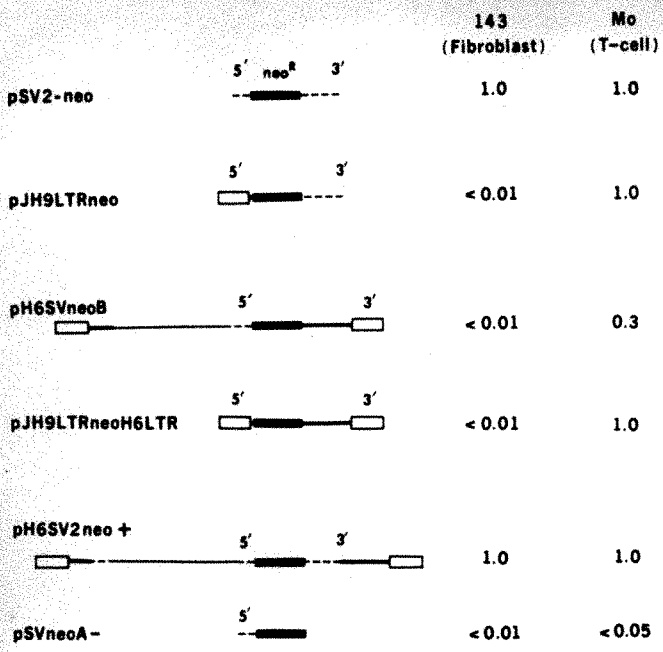

Fig. 3 Relative transfection efficiency of recombinant *neo*^{R} genes. The different recombinants between SV40, HTLV-II and *neo*^{R} sequences are shown schematically. HTLV-II sequences are indicated by dark lines; HTLV-II LTR by open boxes; SV40 sequences by dotted lines; *neo*^{R} sequences by solid bars and pBR322 sequences by thin lines. 5′ and 3′ indicate the orientation with respect to expected transcription initiation sequences and termination sequences, respectively. The 5′ LTR in pJH9LTRneo and pJH9LTRneoH6LTR are joined to the *neo*^{R} gene by an *Eco*RI site which is located 3 bp from the tRNA^{Pro} primer binding site[20]. All constructs are propagated as plasmids of pBR322 derivatives. Details of the constructs are available on request.

Methods: 143 cells[11] were transfected by the calcium phosphate precipitation method with serial fivefold dilutions of the plasmid DNA. Colonies of cells resistant to 200 μg ml^{-1} G418 were counted after 2 weeks. 10^7 Mo cells were transfected by the spheroplast fusion method[26] and plated at $1.0–3.0 \times 10^5$ viable cells (viability ~50%) per well of a 24-well culture dish. The number of stably transfected cells resistant to 500 μg ml^{-1} G418 was determined by the proportion of wells in which cells grew after 5–6 weeks of culture. The efficiency of transfection using the SV40 vector pSV2-neo[10], which contains the SV40 early promoter and termination sequences, was about 5×10^{-6}. Because of some variability between transfection experiments performed at different times, the efficiency of transfection was determined relative to pSV2-neo in each experiment.

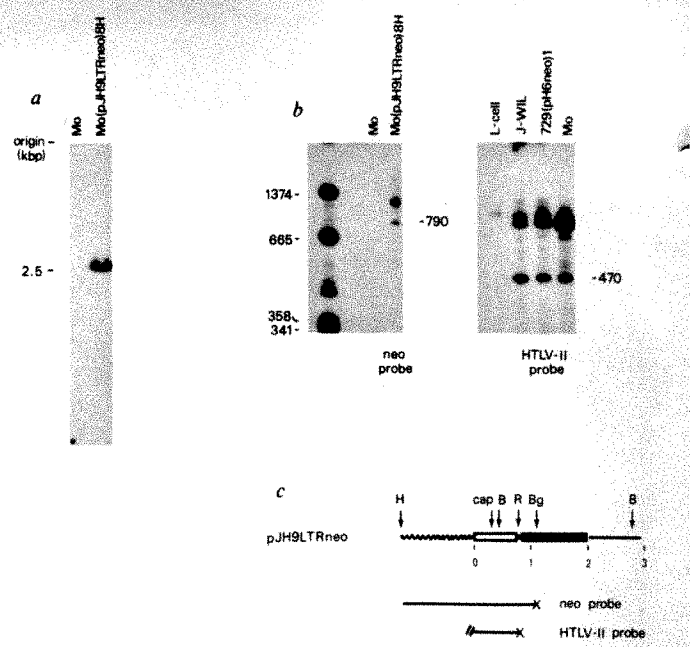

Fig. 4 pJH9LTRneo DNA and RNA sequences in a clone of transfected Mo cells, Mo(pJH9LTRneo)8H. *a*, DNA from Mo(pJH9LTRneo)8H digested with *Bam*HI and hybridized[18] with a ^{32}P-labelled DNA fragment consisting of only *neo*^{R} sequences. The DNA fragment of 2.5 kb is the expected size for the *Bam*HI fragment of pJH9LTRneo (see map in *c*). *b*, S_1 nuclease analysis of *neo*^{R} containing RNA in Mo(pJH9LTRneo)8H (left panel) using a 5′ end-labelled *neo*^{R}-specific probe. S_1 nuclease analysis of HTLV-II RNA (right panel) using an HTLV-II specific probe is shown for comparison. The protected DNA fragments indicated, 790 and 470 nucleotides, are of the size expected for transcription initiation from the cap size of the HTLV-II LTR. The larger protected fragment with RNA from Mo(pJH9LTRneo) results from protection of the entire HTLV-II LTR sequences (beyond the cap site to the 5′ end). This protection is a consequence of hybridization of the U3R sequences at the 3′ end of HTLV-II RNA to the U3R LTR sequences in the probe thereby further protecting the probe to the 5′ end of the LTR. More sensitive mapping with shorter probes showed that the precise 5′ end of the LTR is protected (data not shown). Similar larger protected DNA fragments are observed with the HTLV-II specific probe (right panel, middle band). The largest fragment observed with the HTLV-II specific probe is the size of the full length probe, a result of incomplete S_1 digestion and also visible in the L-cell control lane. *c*, Schematic map of pJH9LTRneo. Symbols are as in Fig. 3 except that wavy lines represent human cell DNA sequences. The 5′ end-labelled probes for S_1 analysis are shown. The HTLV-II probe is derived from the equivalent region of the 5′ LTR of λH6 (Fig. 1*c*) up to the 5′ *Eco*RI site in human cell DNA. The numbers beneath the map indicate the size in kb. The cap site of HTLV-II is indicated. H, *Hin*dIII; R, *Eco*RI; Bg, *Bgl*II; B, *Bam*HI.

pSVneoA-. Thus, termination of transcription by the HTLV-II LTR may also be restricted in 143 cells.

Our results demonstrate that in 143 fibroblast cells the HTLV-II LTR functions poorly, if at all, to promote transcription of stable mRNA, in contrast to the Mo cells where the LTR functions efficiently. This pattern parallels that of expression of HTLV-II proviral sequences in 143 and Mo cells (Fig. 1). Note that other retroviruses, Kirsten murine leukaemia–sarcoma virus and simian sarcoma-associated virus, have been shown to replicate in 143 cells[19]. Therefore, a *cis*-acting property of the HTLV-II LTR appears to be directly responsible for the lack of HTLV-II expression in the non-lymphoid cells tested.

We recently determined the sequence of the HTLV-II LTR[20], and found a sequence of 21 nucleotides, repeated three times in the same orientation, present in U3 upstream from the 'TATAA' box. Although most sequences of the adult T-cell leukaemia virus (HTLV-I) LTR[21] are distinct from those in HTLV-II, we noted that the 21 nucleotide sequence is highly conserved and repeated in comparable positions of U3. Because this repeated sequence is conserved in regions of the LTR important for transcriptional control, it is possible that this sequence is required as a *cis*-acting signal for the tissue specificity of LTR function.

The specific transcription of HTLV-II sequences in lymphoid cells resembles the specific transcription of immunoglobulin genes in mouse B lymphocytes[16,22,23]. Transfected immunoglobulin genes are expressed at low levels in fibroblasts in contrast to their expression in mouse myeloma cells. Sequences related to enhancer sequences of animal viruses have been shown to be responsible for this tissue-specific expression. It is possible that the factors which control the tissue-specific expression of HTLV and immunoglobulin genes represent basic mechanisms for controlling gene expression during T- and B-lymphocyte development respectively. HTLV has apparently evolved in such a manner as to use that mechanism for its pathogenesis in human T lymphocytes.

Domain interactions of H–2 class I antigens alter cytotoxic T-cell recognition sites

H–2 class I antigens appear to direct the recognition of virus-infected and neoplastic transformed cells by cytotoxic T lymphocytes (CTLs)[1,2]. Here, to identify the regions of class I antigens involved in CTL recognition, four hybrid class I genes were constructed in which exons were exchanged between the *H–2K*^{b} and *H–2D*^{b} genes[3,4]. These class I genes were expressed in mouse L cells and recognition of the hybrid K^b/D^b antigens by CTLs and monoclonal antibodies specific for either K^b or D^b was investigated[4]. The pattern of CTL and monoclonal antibody recognition obtained indicates three correlations between structure and function of class I antigens. First, most CTL recognition sites and alloantigenic determinants are located on domains 1 and 2 of the antigen molecule. Second, these CTL recognition sites and alloantigenic determinants are not influenced by interaction of domains 1 and 2 with polymorphic regions of domain 3. Third, in contrast, interaction between domains 1 and 2 alters these CTL recognition sites and alloantigenic determinants. The alteration of CTL recognition sites by interaction between domains 1 and 2 suggests that a CTL site may be formed by amino acids from both domains 1 and 2, or that the conformation of amino acids at a CTL site may be altered by interactions between domains 1 and 2. Through these two features, the conformation of CTL recognition sites on H–2 class I antigens may be sensitive to alteration by interaction of either domain 1 or 2 with viral antigens.

The four hybrid class I genes constructed consist of two pairs of reciprocal exon exchanges between the *H–2K*^{b} and *H–D*^{b} genes (Fig. 1*a*). Thus, exons 2 were exchanged: the resultant constructs of *K*^{b} exon 2 in the *D*^{b} gene and *D*^{b} exon 2 in the *K*^{b} gene encode hybrid K^b/D^b antigens consisting respectively of a polypeptide with domain 1 of K^b and all other domains from D^b (K^{b}1/D^b) and a polypeptide with domain 1 of D^b and all other domains from K^b (D^{b}1/K^b) (Fig. 1*b*). Similarly, the promoters and exons 1, 2 and 3 were exchanged: the resultant constructs of the *K*^{b} promoter and exons 1, 2 and 3 spliced to the remainder of the *D*^{b} gene and the *D*^{b} promoter and exons 1, 2 and 3 spliced to the remainder of the *K*^{b} gene encode hybrid K^b/D^b antigens, producing, respectively, K^b domains 1 and 2 with all other domains from D^b (K^{b}1+2/D^b) and D^b domains 1 and 2 with all other domains from K^b (D^{b}1+2/K^b) (Fig. 1*b*). Ltk$^-$ cells were co-transformed with the *K*^{b}, *D*^{b} and four *K*^{b}/*D*^{b} hybrid genes and the thymidine kinase (*tk*) gene by $CaPO_4$ co-precipitation[5]. Ltk$^+$ colonies, selected for by growth in the presence of hypoxanthine–aminopterin–thymidine, were picked and screened by antibody binding for cell-surface expression of K^b and/or D^b alloantigenic determinants. The cloned cell lines expressing high levels of K^b, D^b and hybrid K^b/D^b antigens were selected for further study.

The presence or absence of K^b and D^b allodeterminants on the four hybrid K^b/D^b antigens was determined by screening these cell lines with a panel of 18 monoclonal antibodies specific for determinants on either K^b or D^b (Table 1). All these allodeterminants, except one D^b allodeterminant, map to domain 1 or 2. The specificities of 12 monoclonal antibodies were mapped to either domain 1 or 2; these locations were basically in agreement with clusters of allodeterminants defined by binding inhibition studies[6]. The D^b-specific antibody 28-14-8 mapped to domain 3; the allodeterminant recognized by 28-14-8 was also present on L^d and has previously been mapped to domain 3 of this antigen[7].

The conformation of domains 1 and 2 in the hybrids K^{d}1/D^b and D^{b}1/K^b seems to differ from that in the parental K^b and D^b antigens. Fifteen out of the 17 parental K^b and D^b alloantigenic determinants located on domains 1 and 2 are either modified or not present on K^{b}1/D^b and D^{b}1/K^b. Thus, five allodeterminants are absent from either of the two hybrids; these are defined by antibodies K7-38, K9-136 and K10-56.1 specific for K^b and H141-29 and K15-25 specific for D^b. Ten allodeterminants are present on one or other of these hybrids, but all are modified, as indicated by markedly reduced levels of binding of the respective antibodies to the hybrids compared with K^b or D^b. The hybrids K^{b}1/D^b and D^{b}1/K^b, however, do retain one and two unaltered allodeterminants respectively, defined by antibody 28-13-3 specific for K^b and antibodies 28-14-8 and B22-249.1 specific for D^b; this indicates that both antigens are expressed at levels similar to K^b and D^b.

Recognition of the four K^b/D^b hybrid antigens by CTLs was investigated with both K^b and D^b restricted influenza virus-specific CTLs and K^b and D^b allospecific CTLs (Table 2, Fig. 2). The pattern of recognition obtained for the two hybrids K^{b}1+2/D^b and D^{b}1+2/K^b indicates first that the majority of both allospecific and virus-specific CTL recognition sites are on domains 1 and 2, and second, that these CTL recognition sites are not influenced by interaction of domains 1 and 2 with polymorphic regions of domain 3; the amino acid sequence of K^b differs from D^b at 9 residues out of 92 in domain 3 (refs 3, 8). These results for CTL recognition of the hybrids K^{b}1+2/D^b and D^{b}1+2/K^b confirm and extend those obtained for the equivalent L^d/D^d hybrids[9,10].

In contrast, neither the K^{b}1/D^b nor the D^{b}1/K^b hybrid was recognized by either K^b and D^b allospecific or K^b and D^b restricted influenza virus-specific CTLs. This indicates that both allospecific and virus-specific CTL recognition sites, located on domains 1 and 2 of the parental K^b and D^b antigens, are significantly altered on the K^{b}1/D^b and D^{b}1/K^b hybrid antigens. The cell lines 4-1 (which expresses K^{b}1/D^b) and 3-7 (D^{b}1/K^b) were lysed by an influenza virus-specific and K^k-restricted CTL clone (K5)[11] when infected with virus (data not shown). The lack of lysis of 4-1 and 3-7 by K^b and D^b specific CTLs therefore results from failure to recognize the hybrid antigens and not inability of the lines to be lysed.

Table 1 K^b and D^b specific monoclonal antibody binding to hybrid K^b/D^b antigens

The K^b and D^b specific monoclonal antibodies have been characterized previously[6,13,14]. The antibody binding assay was performed in Falcon flat-bottom 96-well microtitre plates. 10^5 cells were added to each well and incubated overnight at 37 °C in Dulbecco's modified Eagle's medium supplemented with glutamine, hypoxanthine, aminopterin, thymidine, penicillin, streptomycin and 10% fetal calf serum. The cells were washed with phosphate-buffered saline containing Ca^{2+}, Mg^{2+} and 1% bovine serum albumin, and incubated with 50 μl per well of a 5× dilution of hybridoma supernatant for 60 min at 4 °C. After washing, the cells were incubated for 60 min at 4 °C with 50 μl per well of ^{125}I-labelled goat anti-mouse IgG containing 100,000 c.p.m. The cells were washed extensively and lysed with 1% Triton X-100; supernatants were collected and radioactivity was determined in a γ counter. Results are expressed as c.p.m. ^{125}I bound; each result is the average from triplicate samples and the variation in all cases was not >7.5%. The binding of an irrelevant monoclonal antibody, specific for the haemagglutinin of influenza virus A/PR8, was <150 c.p.m. on all six cell lines. All 18 K^b and D^b specific antibodies gave binding of <150 c.p.m. to a Ltk^+ cell line 8-1, which was obtained by transfection of Ltk^- cells with the *tk* gene alone. Three antibodies that react with determinants on $H\text{-}2^k$ class I antigens, H142-23.3, H142-45 and Y-3 (ref. 13), gave binding to the cell line 8-1 of 4,387, 551 and 6,147 c.p.m., respectively. This suggests that the level of expression of K^b, D^b and the four hybrid K^b/D^b antigens is similar to that of endogenous $H\text{-}2^k$ class I antigens of the L cells.

Thus, the pattern of CTL and monoclonal antibody recognition obtained for the two hybrid antigens, K^b1/D^b and D^b1/K^b, indicates that interactions between domains 1 and 2 of the hybrids alter parental K^b and D^b CTL recognition sites and alloantigenic determinants located on these domains. Two possible, not mutually exclusive, models would explain the alteration of CTL recognition sites and alloantigenic determinants. First, the sites recognized by CTLs or monoclonal antibodies may be formed by amino acids from both domains 1 and 2. Thus, for example, amino acids from D^b domain 1 that form part of a CTL/antibody site are replaced by different residues from K^b domain 1 in the hybrid K^b1/D^b. Second, the CTL/antibody sites may be formed by amino acids entirely from one domain. In this case, the conformation of a CTL/antibody site on D^b domain 2 in the hybrid K^b1/D^b, for example, would be altered by interaction of this domain with K^b domain 1. Thus, K^b differs from D^b at 13 amino acid residues out of 90 in domain 1 and at 20 residues out of 92 in domain 2 (refs 3, 8); these differences between K^b and D^b in domains 1 and 2 result in alteration of CTL/antibody sites on the hybrid antigens K^b1/D^b and D^b1/K^b.

Sherman[12] has proposed that H-2 restriction of CTLs may represent the recognition of conformational alterations of class I antigens resulting from interaction with viral antigens. Our report suggests that the conformation of a CTL recognition site

Table 2 Polyclonal allospecific and influenza virus-specific CTL recognition of hybrid K^b/D^b antigens

	K^b/D^b antigen Cell line	% Specific ^{51}Cr release (K:T = 20:1) K^b 1-3	D^b 2-5	D^b1/K^b 3-7	K^b1/D^b 4-1	D^b1+2/K^b 6-2	K^b1+2/D^b 5-6

Anti-allo K^b		34	−2	5	−2	−5	19

D^b and K^b restricted CTLs specific for influenza virus A/X31 were obtained from spleens of B10.HTG (K^dD^b) and B10.A(5R) (K^bD^d) mice respectively primed by intravenous injection with 10^7 A/X31 infected syngenic spleen cells. Allospecific CTLs were generated by *in vitro* stimulation of BALB/c (K^dD^d) spleen cells twice with irradiated (3,000 rad) B10.A(5R) (K^bD^d) for anti-K^b or twice with irradiated B10.HTG (K^dD^b) and once with irradiated B10.BYR (K^qD^b) spleen cells for anti-D^b. Ltk^+ target cells infected with influenza virus were prepared as follows: the cells were trypsinized and plated overnight on bacteriological Petri dishes, for easy resuspension, before infection with *A/X31* and ^{51}Cr-labelling for 1 h at 37 °C. The conditions for infection of the targets and the protocol for the 6-h cytotoxicity assay were as described previously[15]. The % virus-specific ^{51}Cr release was calculated by subtraction of ^{51}Cr release from uninfected targets. The % allospecific ^{51}Cr release was calculated by subtraction of ^{51}Cr release from a Ltk^+ cell line 8-1, which was obtained by transfection of Ltk^- cells with the *tk* gene alone. A CTL to target ratio (K:T) of 20:1 was used for all four polyclonal populations.

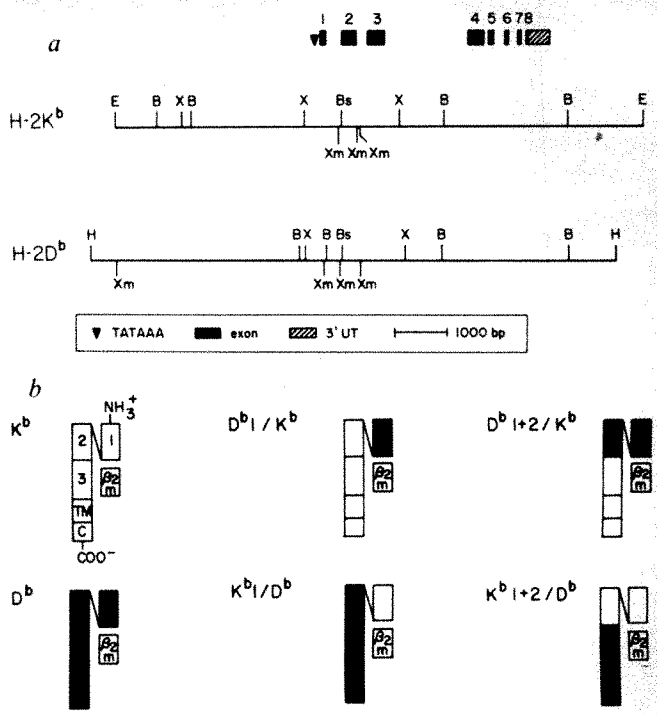

Fig. 1 *a*, Restriction maps of $H\text{-}2K^b$ and $H\text{-}2D^b$ genes. *b*, Domain structure of K^b/D^b and four K^b/D^b hybrid antigens. In *a*, E = *Eco*RI; B = *Bam*HI; Bs = *Bss*HII; H = *Hin*dIII; X = *Xba*I; Xm = *Xma*I. The restriction sites shown are those used to construct and confirm orientation of exon exchanges. The location of the promoter and exons of the K^b gene are shown[3]. Exons 1, 2 and 3 of the D^b gene are located in the 2,200-base pair (bp) *Bam*HI fragment that contains the *Bss*HII site. Exons 4, 5, 6, 7 and 8 are located in the adjacent 2,400-bp *Bam*HI fragment (unpublished data). The restriction sites used to isolate D^b exon 2 and exons 2 and 3 are not present in the nucleotide sequence of a D^b cDNA clone[3], which indicates that these sites are located in introns of the D^b gene. In *b*, 1, 2 and 3 are external domains 1, 2 and 3 (alternatively designated N, C1 and C2, respectively[16]); TM, transmembrane segment; C, cytoplasmic domain; β_2M, β_2-microglobulin. H-2 class I antigens are cell-surface glycoproteins of molecular weight (MW) 45,000 associated noncovalently with β_2-microglobulin, MW 12,000. The class I polypeptide can be divided on the basis of its primary structure into three external globular domains, each of about 90 amino acids, a transmembrane segment of ~40 residues, and one cytoplasmic domain of 30 residues[16]. The diagrammatic representation of the H-2 class I antigen is supported by the observation that domains 1 and 2 are stable in isolation and that domain 3 is associated with β_2-microglobulin[17].

Methods: The four hybrid K^b/D^b genes shown in *a* were constructed as follows: (1) Exchange of exon 2 between D^b and K^b. The K^b and D^b genes were subcloned in the *Eco*RI and *Hin*dIII sites of pBR327, respectively. The K^b and D^b exons 2 were isolated as *Xma*I 330- and 390-bp fragments, respectively; these fragments contain the *Bss*HII site. The D^b *Xma*I 390-bp fragment was inserted directly into a K^b gene subclone, linearized with *Xma*I, from which both *Xma*I fragments of 330 and 50 bp had been deleted. This deletion was obtained by complete digestion of the K^b subclone with *Xma*I and ligation at dilute concentration of DNA to favour recirculation of the vector minus the two fragments. The K^b *Xma*I 330-bp fragment was inserted first into a D^b 5′ gene subclone of the 2,200-bp *Bam*HI fragment, linearized with *Xma*I, from which the *Xma*I fragment of 390 bp had been deleted. This deletion was obtained by complete digestion of the D^b 5′ gene subclone with *Xma*I and ligation at dilute concentration of DNA. Second, a 1,200-bp *Xba*I–*Bss*HII fragment was isolated from the D^b 5′ gene subclone and inserted in the complete D^b gene subclone, linearized by partial digestion with *Xba*I and complete digestion with *Bss*HII. (2) Exchange of promoter and exons 1, 2 and 3 between K^b and D^b. The K^b and D^b promoters and exons 1, 2 and 3 were isolated from the subclones of the two genes as *Xba*I fragments of 1,800 and 1,850 bp, respectively. The corresponding K^b and D^b 3′ gene *Xba*I fragments of 8,000 and 11,500 bp, respectively, were isolated from the same digests; these fragments also contain the pBR327 vector sequence. The K^b *Xba*I 1,800-bp fragment was ligated to the D^b *Xba*I 11,500-bp fragment; similarly, the D^b *Xba*I 1,850-bp fragment was ligated to the K^b *Xba*I 8,000-bp fragment. Restriction enzyme digest conditions were as recommended by New England Biolabs. Restriction fragments were separated by electrophoresis in low melting temperature agarose gels; fragments were isolated by melting gel slices at 65 °C and phenol extraction. Purified fragments were ligated with T4 DNA ligase in 50 mM Tris *p*H 8.0, 7.5 mM $MgCl_2$, 1 mM ATP and 10 mM dithiothreitol for 3 h at 15 °C. Vector fragments were first treated with calf intestinal phosphatase in 50 mM Tris *p*H 9.0, 1 mM $MgCl_2$, 0.1 mM $ZnCl_2$ and 1 mM spermidine for 1 h at 37 °C. Ligated DNAs were introduced into $CaCl_2$-treated *Escherichia coli* DH1 or HB101 cells[18]. Colonies were picked and constructs were identified by restriction enzyme digests on plasmid mini-preps[18]. DNA for transfection of Ltk⁻ cells was isolated from plasmid maxi-preps[18]; exon exchange and correct orientation of insertion were confirmed by restriction mapping.

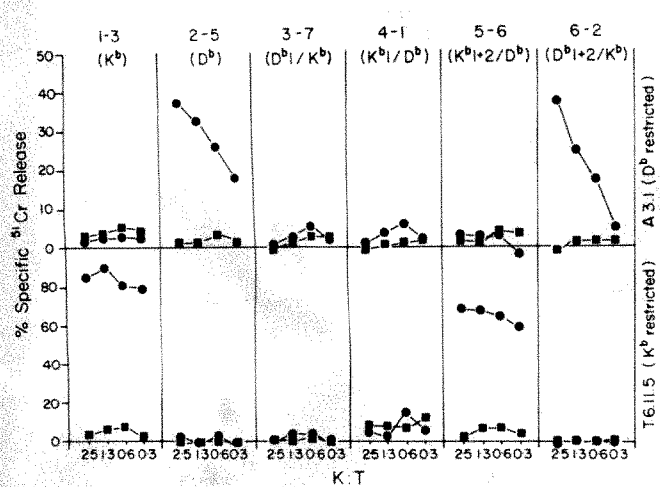

Fig. 2 Cloned influenza virus-specific CTL recognition of hybrid K^b/D^b antigens. The A/X31 influenza virus-specific CTL clones A3.1, D^b-restricted, and T6.11.5, K^b-restricted, were selected and maintained with antigen and T-cell growth factor as described previously[19]. Target cells were prepared and the 6-h cytotoxicity assay was performed as described in Table 2 legend. ●, A/X31-infected target cells; ■, uninfected target cells; K:T, CTL to target ratio. The upper graphs show lysis by D^b-restricted clone A3.1; the lower graphs show lysis by K^b-restricted clone T6.11.5.

may be sensitive to alteration by interaction of either domain 1 or 2 with a viral antigen.

We thank Gunter Hammerling, Keiko Ozato and David Sachs for supplying monoclonal antibodies; Susan Calvin and Pat Taylor for assistance with cell culture; and Madlyn Nathanson for assistance in preparing the manuscript. This work was supported by Biogen N.V.

Two mechanisms of expression of a predominant variant antigen gene of *Trypanosoma brucei*

Peter Myler*, Richard G. Nelson†, Nina Agabian† & Kenneth Stuart*

* Issaquah Health Research Institute, 1595 NW Gilman Blvd, Issaquah, Washington 98027, USA
† Department of Biochemistry, University of Washington, Seattle, Washington 98195, USA

African trypanosomes evade the host immune response by periodically switching their variant surface glycoprotein (VSG) coat[1–3]. The resulting, serologically distinct variant antigenic types (VATs) appear in a loosely ordered sequence and those arising early in infections are termed predominant VATs[4–8]. VAT switching reflects the successive transcriptional activation of single VSG genes from a large repertoire. Activation of some VSG genes is accomplished by duplication of a previously silent basic copy (BC) gene and insertion of this expression linked copy (ELC) near a chromosomal telomere where it is expressed[9–16]. However, other VSG genes, always located near a telomere, use a non-duplication activation (NDA) mechanism[16–19]. We report here that the gene encoding the predominant IsTat 1.A VSG can be activated with or without duplication. Four of six independently derived clones activated the 1.A gene without gene duplication or detectable rearrangement. The other two contained an active 1.A ELC, possibly generated by a gene conversion extending to the end of the telomere. The ability to utilize both NDA and ELC mechanisms of gene activation and perhaps an alternative mechanism for gene duplication may account for the fact that VAT 1.A is the most predominant VAT of the IsTaR 1 serodeme.

Derivation of the IsTaR 1 serodeme has been described previously[20]. Many immune competent rats, mice or *Peromyscus* singly infected with different IsTaR 1 VATs produced first relapse populations that were invariably 100% VAT 1.A. Thus, 1.A is the most predominant VAT of the IsTaR 1 serodeme. Each of six independently derived 1.A clones (Fig. 1) reacted with four monoclonal antibodies which recognize different epitopes of the 1.A VSG molecule (P.M., unpublished results), indicating that they all expressed the same VSG. The mechanism of 1.A VSG gene activation in these clones was examined by genomic Southern analyses. Figure 2*a* shows an autoradiogram of *Sal*I-digested DNA from five clones which do not express 1.A VSG (1.D, 1.3, 1.5, 1.7, 1.11), five 1.A clones from the first relapses of each of these ($1.A^1$, $1.A^3$, $1.A^5$, $1.A^7$, and $1.A^{11}$), a subclone of the original IsTat 1.A (1.Ae), and two clones derived from a first relapse population of IsTat 1.A (1.1^A and $1.X^A$). The VAT is indicated after the point (for example, 1.Ae), the parent VAT is indicated by a superscript, and a lower case letter is used to designate clones when needed. The 1.A VSG cDNA probe, which contains one *Sal*I site (Fig. 2*d*) also present in each genomic copy of the gene, hybridizes to four *Sal*I fragments in 1.Ae and $1.A^7$ and to three fragments in each of the other clones (Fig. 2*a*). The band at 1.1 kilobases (kb) is composed of co-migrating fragments extending from the internal *Sal*I site to another *Sal*I site present at the same location 5′ to each 1.A gene. The remaining *Sal*I fragments contain the 3′ ends of these genes and allow determination of the number of 1.A genes present in each clone. Like the original VAT 1.A (1.Ae, 15 and 16), the relapse clone $1.A^7$ contains a 1.A ELC. However, no 1.A ELC is present in four other relapse-derived 1.A clones ($1.A^1$, $1.A^3$, $1.A^5$ and $1.A^{11}$). The latter clones, their parent VATs (1.1, 1.3, 1.5 and 1.11) and all other heterologous VATs we have examined (for example, 1.7, $1.X^A$ and 1.1^A) contain only two copies of the 1.A gene. One copy, present on a 13.5-kb *Sal*I fragment, is located in a non-telomeric region and has been cloned in λ_{1059} and extensively mapped (Fig. 4). The other copy is located near a telomere, as evidenced by its size variation among VATs (5–8 kb, Fig. 2*a*) and the presence of a 'universal restriction site' 3′ to the gene (Fig. 4). These data suggest that an ELC is present in some 1.A expressors but absent in others.

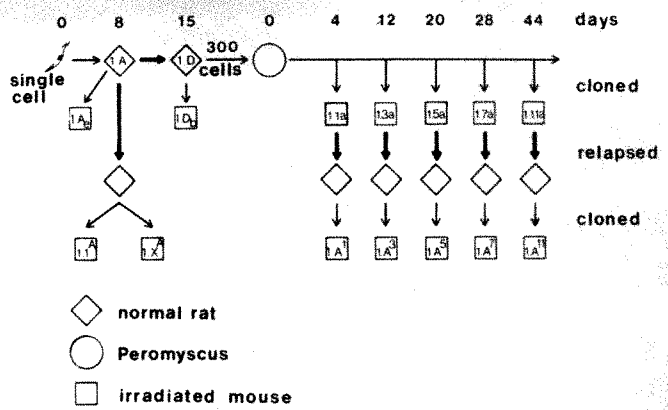

Fig. 1 The IsTAR 1 serodeme[20] was initiated with a single trypanosome cloned from a population of which ~70% of the cells expressed 1.A. The first parasitaemia (day 8) population was designated IsTat 1.A. Three hundred cells of the first relapse population (1.D, day 15) from the same immune competent rat, were injected into a deermouse, *Peromyscus leucopus*. Samples were taken at 4-day intervals, expanded in lethally irradiated mice and then cloned to obtain the VATs shown. Clone 1.Db expresses the same VSG as 1.1a (ref. 15) and thus VAT 1.1 cells were derived from the growth of VAT 1.D cells without an intervening antigenic switch. Approximately 5–500 trypanosomes from each of the six VATs were injected into immune competent rats and the resulting first relapse populations subsequently cloned. The relapse populations from VATs 1.1, 1.3, 1.5, 1.7 and 1.11 were 100% VAT 1.A re-expressors as determined by their reaction with anti-1.A VSG monoclonal antibodies. The relapse population from 1.A yielded two clones expressing 1.1 VSG (from their reaction with anti-1.1 VSG monoclonal antibodies) and one clone expressing a VAT ($1.X^A$) not recognized by any of our VAT specific antisera.

An alternative interpretation of the above data is that the extra bands in 1.Ae and $1.A^7$ are not ELCs but are due to discrete heterogeneity in the length of telomeric sequences flanking a single 1.A gene. Similarly, the presence of ELCs in $1.A^1$, $1.A^3$, $1.A^5$ and $1.A^{11}$ might be concealed by extensive telomeric size heterogeneity, that is, 'ghost ELCs'[21]. To resolve these issues we digested DNA from each clone with *Hin*cII, which cleaves within the VSG 1.A coding region (Fig. 2*d*) and 3′ to each of the 1.A genes (Fig. 4). This allows analysis of the number of 1.A genes independently of telomeric length variation. The 2.0- and 1.3-kb *Hin*cII fragments present in every DNA shown in Fig. 2*b* contain the 3′ ends and the immediate 3′-flanking sequences of the non-telomeric and telomeric 1.A genes, respectively. Densitometric scans (Fig. 2*c*) show a doubling of intensity of the 1.3-kb band compared with the 2.0-kb band, in 1.Ae and $1.A^7$ but not in the other clones. This confirms the presence of a 1.A ELC in these two clones and its absence in the others, and shows that the other telomeric 1.A gene acted as the BC.

The single telomeric 1.A gene in $1.A^1$ is preferentially sensitive to DNase I (Fig. 3), illustrating that the telomeric BC is transcribed in those clones using the NDA mechanism. It is not preferentially DNase I sensitive in non-1.A expressors (P.M., data not shown). In $1.A^7$ (and 1.Ae, not shown), only the ELC is DNase sensitive (Fig. 3*b*), indicating that the duplicated copy and not the telomeric BC is transcribed. Our results therefore show that IsTaR 1 cells can transcriptionally activate the telomeric 1.A VSG gene by either the ELC or NDA mechanisms. While both mechanisms are used for the expression of different VSG gene families in a single serodeme[16,18] and related VSG genes in different serodemes[22], the present report shows that both mechanisms can be used for the expression of a single VSG gene within one serodeme.

Restriction maps of the 1.A VSG genes were constructed by genomic Southern analyses (Fig. 4). Each copy of the 1.A gene has an identical restriction map spanning the coding region from the 5′ *Sal*I site to the 3′ *Acc*I site. Outside this region the

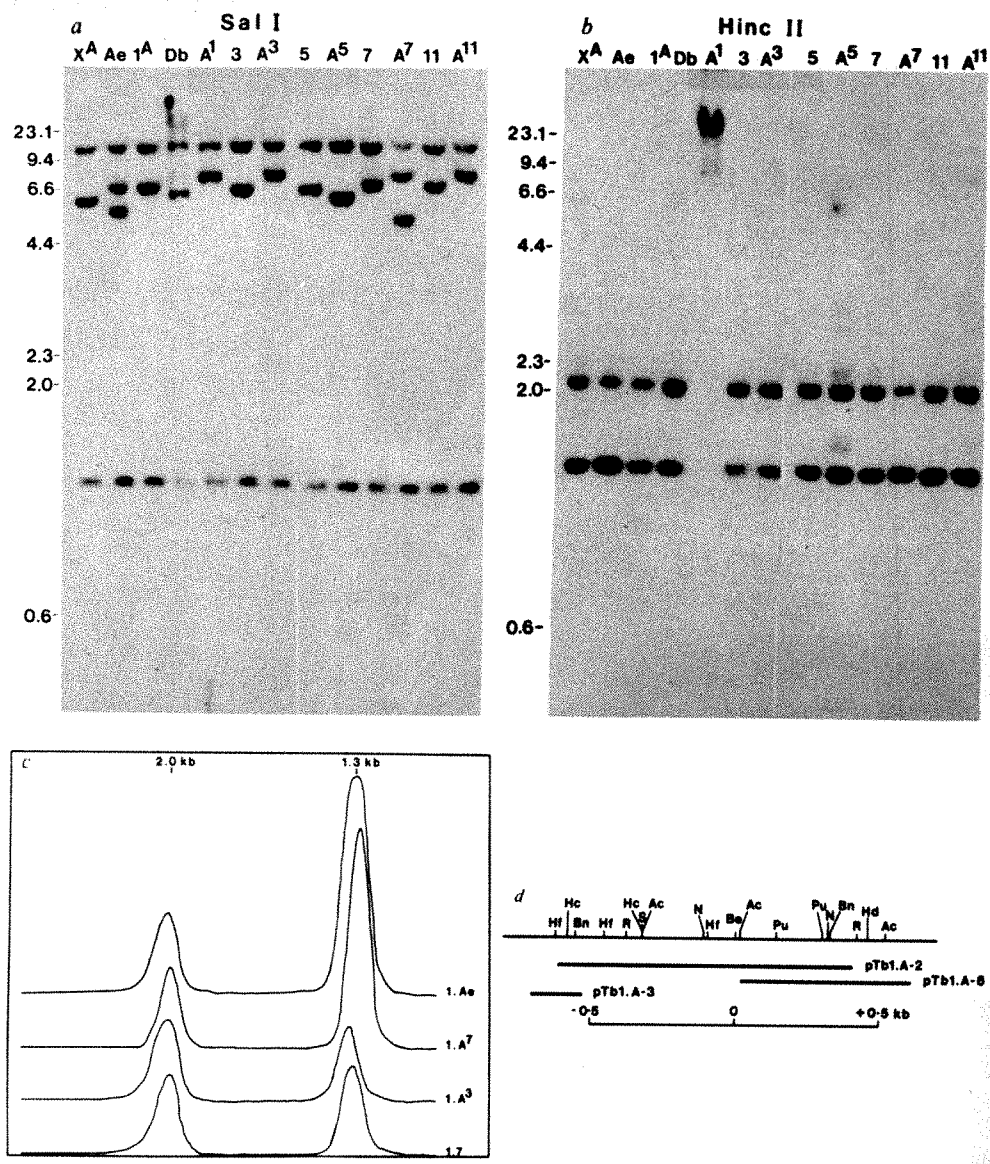

Fig. 2 Southern blot analysis of the 1.A genes in early VATs and cloned relapses. DNA isolated from VATs IsTat 1.X^{A}, 1.Ae, 1.1^{A}, 1.Db, 1.A^{1}, 1.3a, 1.A^{3}, 1.5a, 1.A^{5}, 1.7a, 1.A^{7}, 1.11a and 1.A^{11} (see text for VAT nomenclature) was digested with restriction endonucleases *Sal*I (*a*) or *Hin*cII (*b*) and size-fractionated through 0.6% agarose gels. DNA isolated from VATs 1.Db digested with *Sal*I and 1.A^{1} and 1.A^{5} digested with *Hin*cII did not digest to completion and the small internal and 5′ *Hin*cII fragments ran off the gel in *b*. The gels were blotted bi-directionally onto nitrocellulose filters[35–37], then hybridized with a 1.A cDNA clone (pTb1.A-2) labelled with ^{32}P by nick-translation[38]. Size markers were *Hin*dIII, *Xba*I and *Kpn*I digests of λ DNA and their positions are indicated next to each autoradiogram. *c*, Densitometric scans of autoradiograms from *Hin*cII digests *b* normalized to give the same peak heights for the 2.0-kb band in each of the DNA digests. *d*, Restriction map of clones isolated from a cDNA library prepared from IsTat 1.A (refs 15, 16). Abbreviations used for restriction endonuclease sites are: A, *Ava*I; Ac, *Acc*I; B, *Bam*HI; Be, *Bst*EII; Bg, *Bgl*I; Bl, *Bgl*II; E, *Eco*RI; Hc, *Hin*cII; Hd, *Hin*dIII; Hf, *Hin*fI; P, *Pst*I; Pv, *Pvu*I; Pu, *Pvu*II; R, *Rsa*I; S, *Sal*I; Sp, *Sph*I; Ss, *SSt*I; Xh, *Xho*I.

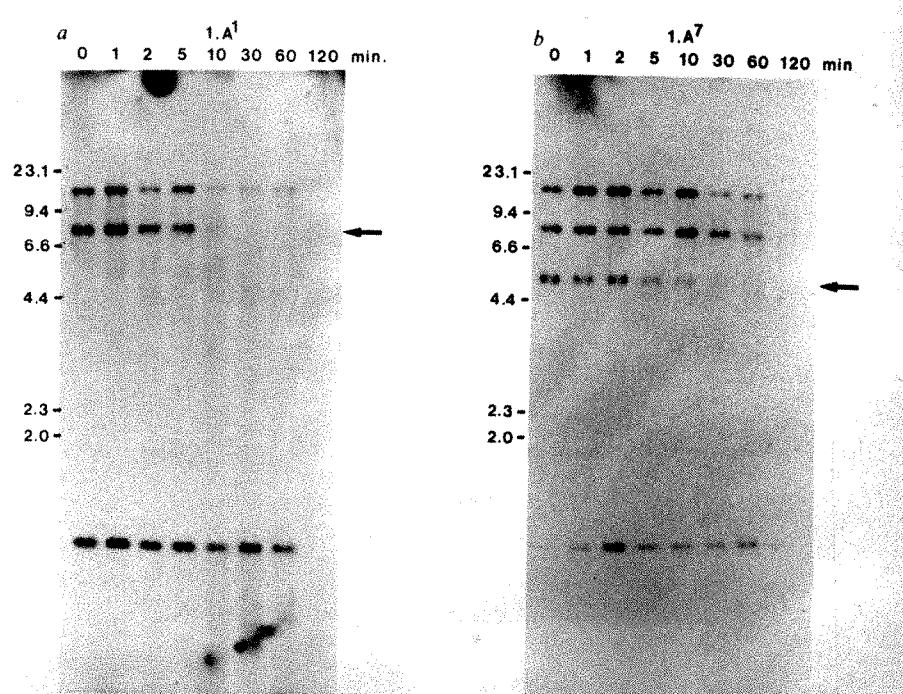

Fig. 3 DNase I sensitivity of IsTat 1.A genes. Frozen trypanosome pellets from 1.A^{1} (*a*) and 1.A^{7} (*b*) were solubilized with Nonidet-P40 and treated with DNase I using the methods of Pays *et al.*[12]. DNase I digested aliquots from the times indicated were deproteinized, digested with *Sal*I, electrophoresed in a 0.7% agarose gel and then blotted onto nitrocellulose. The filter was then hybridized with the 1.A probe (pTb1.A-2). The preferentially digested fragment from the expressed gene copy is indicated by an arrow.

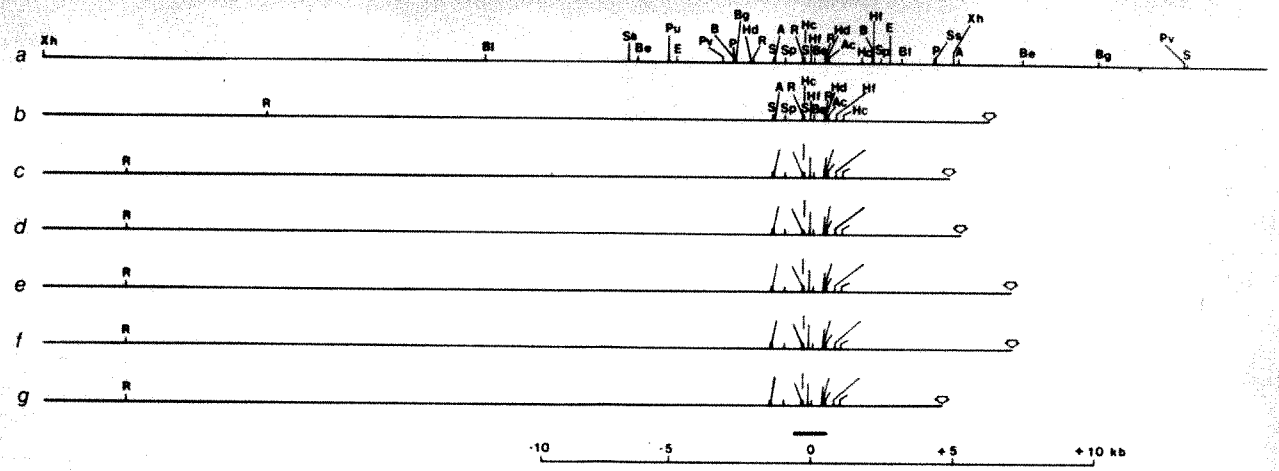

Fig. 4 Restriction maps of IsTat 1.A genes. *a*, The non-telomeric gene in all VATs. *b*, *c*, The ELC and telomeric BC genes, respectively, in IsTat 1.Ae. *d*, *e*, The telomeric gene in IsTat 1.Db and IsTat 1.A[1]. *f*, *g*, The telomeric BC and ELC, respectively, in 1.A[7]. Restriction cleavage sites were determined by Southern hybridization analyses of genomic DNA (see, for example, Fig. 2). Several sites within the coding region have been omitted for clarity (see Fig. 2*d*). The abbreviations for restriction endonucleases used are shown in Fig. 2. The arrow denotes a 'universal restriction site' (*Sal*I, *Ava*I, *Sph*I and *Bst*EII), indicating the telomeric end of a chromosome. The line above the scale indicates the 1.A VSG coding region.

non-telomeric gene (Fig. 4*a*) and telomeric genes (Fig. 4*b–g*) have different restriction maps. Except for the length of the telomere, the maps of the telomeric BC gene (Fig. 4*c–f*) are identical in all clones, whether or not the gene is expressed. Similarly, the map of the 1.A[7] ELC (Fig. 4*g*) is identical to that of the telomeric 1.A[7] BC (Fig. 4*f*). The 1.Ae ELC map, however, differs from these (Fig. 4*b*). The 5′ 'barren' region is 5 kb shorter and the relative order of restriction sites 5′ to the *Rsa*I site distinguishes these telomeric expression sites (P.M., data not shown). The use of more than one expression site has also been seen with other ELCs in the IsTaR 1 serodeme[23] and in the BoTaR serodeme of *Trypanosoma equiperdum*[24], but is in contrast to previous results in *T. brucei*[2,25]. To characterize these expression sites further, blots of restriction digests producing large (up to 50 kb) segments of 1.A 5′ flanking sequence were hybridized with a synthetic probe complementary to a portion of the 35-nucleotide spliced leader found on the 5′ termini of all VSG mRNAs[26,27]. Although the probe hybridized with the large tandem array of directly repeated 1.4-kb units[28,29] previously suggested to be the VSG gene expression site promoter[29], and with orphons[28,30], it did not hybridize to the large fragments containing the 1.A gene. Therefore, none of these spliced leader encoding sequences is within 50 kb of either the expressed or non-expressed 1.A genes.

Both non-telomeric[12,31,32] and telomeric[24,25,33,34] BC genes can be duplicated to form ELCs. The ELCs in both 1.Ae and 1.A[7] are duplicated from the telomeric gene, since all their restriction maps are identical 3′ to the 'barren' region and different from the map of the non-telomeric gene, especially the 3′ *Hin*cII and *Hin*fI sites (Fig. 4). The duplicated segment extends minimally from the 5′ *Sal*I site to the 3′ *Hin*cII site and maximally from the 5′ *Rsa*I site to the end of the chromosome (Fig. 4). In 1.Ae, the 5′ duplication boundary is between the 5′ *Sal*I and *Rsa*I sites. Because the 5′ maps of the ELC and BC genes in 1.A[7] are identical, the boundary in this case may be further upstream. The 3′ duplication boundary in both 1.Ae and 1.A[7] must lie 3′ to the *Hin*cII site. Thus, the ELCs in 1.Ae and 1.A[7] may not result from duplication/transposition of a small 3–5-kb BC 'cassette' spanning the VSG coding region[12,26,27], but rather from a gene conversion initiated 5′ to the coding region and extending to the end of the chromosome. Such a model is consistent with the results presented here and by others[25,34].

We have described a predominant VAT whose VSG gene can be expressed by both the NDA and ELC mechanisms. The fact that the telomeric 1.A gene can be activated by both mechanisms presumably allows its more frequent expression. Furthermore, the similarity between the genomic environments of the basic copy gene and the 'expression site(s)' as shown here and elsewhere[25], may increase the probability of recombination between these two sites. The predominance of 1.A may thus be due to its ability to use alternative mechanisms for VSG gene activation, coupled with a higher frequency of recombination/gene conversion.

DNA variation and evolution

FERRIS, Sage and Wilson[1] assayed wild-caught and inbred strains of mice (*Mus domesticus*) for variation in mitochondrial DNA (mtDNA) using restriction enzyme digestion. They concluded that the data showed either a common origin of 'old' inbred strains (probably a single female) or contamination from a single strain because all the 'old' inbred strains appeared to share a common mtDNA pattern found rarely (2 mice in 56 tested) in their survey of wild populations.

Their observations were made on samples of single mice from each of 14 inbred laboratory strains (5 'new' and 9 'old') and 15 wild populations; further samples of two and three mice were from two different origins. Thirty-six additional wild mice (origin not stated) were assayed using two restriction enzymes which could discriminate the 'old–inbred' pattern. When all members of a sample of size N are identical for a particular pattern, the 95% confidence intervals on the frequency of that pattern are: for $N = 1$, 0.025–1.00; for $N = 2$, 0.158–1.00; for $N = 3$, 0.292–1.00. Because the size of samples used in these experiments was small, it is possible that substantial levels of variation could remain undetected within the wild populations. Whilst the data may suggest a common origin of the 'old' inbred strains, the lack of data on variation within the wild populations precludes the elimination of the alternative hypothesis of independent origin.

In another paper, Coen, Thoday and Dover[2] based their estimation of rates of 'turnover' in structural variants of the ribosomal gene of *Drosophila melanogaster* on samples of two X chromosomes extracted from 10 pairs of iso-female lines and samples of 'at least two (usually three' X chromosomes from population cages established with a mixture of all iso-female lines. The authors assumed that if a variant was present in at least two sublines, it was probably derived from the founding population. On this basis no novel variants were detected in the paired iso-female lines and the rate of 'turnover' was estimated by assuming that no novel variants had been identified. However, no allowance was made for either the size of the samples or the sizes of the populations from which the samples were extracted. The maximum frequency at which novel variants could exist in all sublines and yet remain undetected ($P = 0.05$) in samples of 2 from 20 sublines is ~0.07. In other words, the iso-female lines could be segregating for novel variants at fairly high frequencies and these would not be detectable because of the small sample sizes.

If these putative variants have arisen since the establishment of the lines, then the maximum rate of their production (m, the mutation or 'turnover' rate) is about 3.74×10^{-4} per generation which is of the same order as values obtained by Coen *et al*[2]. However, these estimates assume that the populations are large and no allowance is made for the finite size of the subline populations. Downes[3] gives estimates of the effective population sizes (N_e) of the OK iso-female lines of between 90 and 400. At these values of N_e and m, the effects of the random sampling of gametes in each generation could have a considerable effect on the fate of new variants because the majority will be lost in the first generation. Consequently, the chances of detecting 'turnover' would be low in such small populations and the measurement of its rate made more difficult by the small sample sizes. Similarly the small samples taken from the cage populations and absence of any information on the effective population sizes restrict the interpretation of the data. The results quoted by Coen *et al.* provide no reasonable *prima facie* evidence of systematic change in the frequency of rDNA structural variants. The estimates of 'turnover' rates are based on the assumption that 'turnover' is occurring, not on a demonstration of its existence.

The reports of both Ferris *et al.*[1] and Coen *et al.*[2] describe the application of the techniques of molecular biology to investigate evolution. The procedures have exposed a range of variation which evolutionary biologists must consider seriously. However, the fascinating interpretations presented in these papers are not strongly supported by the data because alternative hypotheses cannot be eliminated. Acceptance of the conclusions of the two reports must await the availability of more data.

FERRIS *ET AL.* REPLY—'Concluded' is too strong a term to apply to the various possible explanations we *offered* for the remarkable finding[1] that all nine of the 'old inbred' strains of laboratory mice tested share a type of mtDNA whose frequency is low (0.04) in wild mice (*Mus domesticus*). This finding contrasts sharply with published protein-electrophoretic evidence indicating that the nuclear genes of these laboratory strains are about as different from one another as are randomly picked nuclear alleles in wild mice[1]. It was important not only to bring our finding to the attention of a wide audience but also to consider how to explain this puzzling contrast in light of the evidence that the mode of inheritance of mtDNA molecules differs from that of nuclear genes in being maternal.

Since these nine strains seen from published breeding records to be founded from at least five non-laboratory females, we calculated the probability of picking five mice with the 'old inbred' type at random from the wild. By 'at random from the wild', we meant at random geographically within the entire range occupied by wild members of the species *M. domesticus*. The best estimate of this probability, based on the frequency observed in our wild survey, is $(0.04)^5$, that is, 10^{-7}. This value, which has been confirmed by a more extensive survey[2], was so low that it led us to ask whether: (1) the five founding females were picked nonrandomly; (2) there was selection for the old inbred type; (3) there was frequent, unrecorded, contamination of one laboratory strain by another's mtDNA.

It was our position[1], which our subsequent work on many additional mice confirms[2–4], that none of these possible explanations for the mtDNA uniformly of the old inbred strains can yet be ruled out.

With regard to nonrandom sampling, we pointed to published evidence that most or all of the founding females came from the pet mouse trade. Drift or selection within this population could have brought about a high frequency of the 'old inbred' type of mtDNA. Alternatively, most of the wild mice used to establish or maintain the pet mouse population may have been trapped in a geographically nonrandom way, that is, from a particular region in which the 'old inbred' type happened to be at high frequency. Our initial survey of mtDNA in wild mice was a wide-ranging one, designed to detect all the major mtDNA lineages in *M. domesticus*[1]. We were aware that until a much more extensive survey of mtDNA variability within and between wild populations of *M. domesticus* was conducted, this alternative could not be evaluated. Subsequent survey work[2–4] bringing the total number of wild *domesticus* mtDNAs tested to 145, has confirmed our initial estimate of the frequency of the old inbred type; it has also shown, as we anticipated, that while there is heterogeneity within and between some localities as regards

mtDNA variability in *M. domesticus*, this species displays a rather weak tendency for macrogeographical structuring of that variability[2].

COEN *ET AL.* REPLY—Genetic turnover by unequal exchange and its evolutionary consequence of molecular drive is well established in the rDNA multigene family of diverse species, since the classic studies of Don F. Brown and colleagues in 1972 (for recent reviews see refs 1–3). To measure the rate of turnover we monitored, over several hundred generations, the stability of rDNA length variants, the expected products of unequal exchange[4,5], in isofemale lines of *D. melanogaster*[6]. Our experimental design was to compare individual X or Y chromosome rDNA variants taken from within each of several pairs of sublines, which had been established by splitting the F_1 progeny of each isofemale line and maintained separately over the prescribed time. By this means the stability of individual chromosome lineages could be assessed. Given that many X and Y chromosome variants from within subline pairs were shown to be identical (that is, no change was observed within these specific chromosome lineages) we estimated the maximal rate of unequal exchange based on the proper statistic that takes into account all independent unchanged lineages across all subline pairs. If the turnover rate were higher than this maximum, we would expect a smaller number of unchanged lineages than was actually observed. We note that Barrett concludes his 'criticism' with a paraphrase of our own summary that in the time course of the experiment "there is no *prima facie* evidence of systematic change in the frequency of rDNA structural variants".

Barrett's appeal for a larger sample size from each subline pair reveals his failure to understand our experimental design and underlines the dangers of applying statistics and population theory in the blind. Our estimated maximal rate is valid irrespective of the number of chromosomes assayed within each lineage and of problems of drift in small populations: it is based only on the number of individual chromosome lineages, each assayed and considered independently. Hence the statistical estimate of our maximal rate would be improved by a wider sampling of more subline pairs, that is, more lineages, rather than more chromosomes within subline pairs.

100 Hz is not the upper limit of synchronous muscle contraction

SMITH[1] has proposed that 100 Hz is the upper limit of contraction frequency in synchronous muscles—those muscles in which there is a 1:1 correspondence between motor neurone impulses and muscle contractions. In asynchronous muscles, contraction frequency can be much higher than that of the motor neurone impulses. Smith reached his conclusion after demonstrating that whitefly flight muscles with high operating frequency are asynchronous rather than synchronous as was previously thought[2]. 100 Hz may represent an upper limit of wing stroke frequency for synchronous flight muscles, but several synchronous muscles have significantly higher operating frequencies, notably sound-producing muscles in bats, fish, crustacea and insects[3–9].

We have studied cicada tymbal muscles, which contract at high frequency during sound production. These muscles are especially pertinent because a wide range of contraction frequencies is found by examining different species[10] and because both synchronous and asynchronous tymbal muscles occur[11]. Our physiological and fine-structural data show that some synchronous tymbal muscles operate at over 200 Hz (224 Hz in *Psaltoda claripennis*).

In synchronous muscles, high contraction frequencies are made possible by muscle modifications that result in short twitch duration. A comparison of several species of cicadas having synchronous muscles[10] shows a close correlation between twitch duration and contraction frequency (Fig. 1*a*) which extends over the full range of contraction frequencies. However, one species, *Platypleura capitata*, which has asynchronous muscles[11], is vastly different in that it has a very short cycle period during singing but a relatively long twitch duration. This is to be expected as high operating frequencies

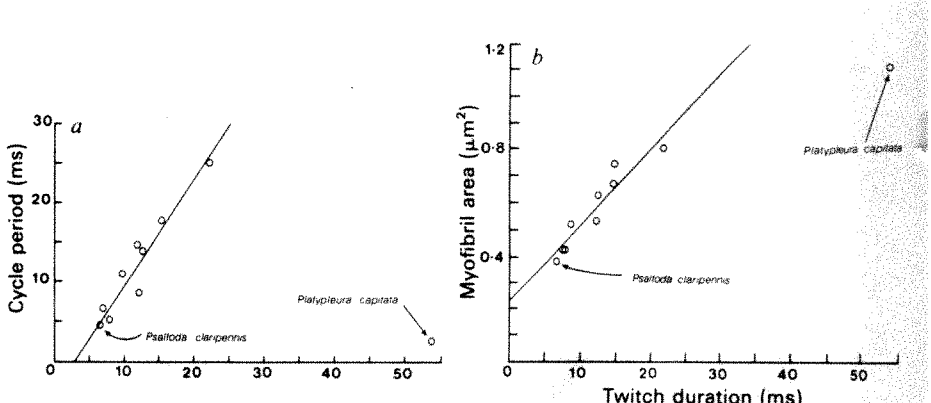

Fig. 1 *a*, The inferred cycle period (=reciprocal of contraction frequency) during the calling song compared with the isometric twitch duration (onset to 50% relaxation, at 30 °C) of the partially isolated tymbal muscles for 10 species of cicada. *b*, Comparison of the myofibril area (measured stereologically from electronmicrographs of transverse sections) with the isometric twitch duration in tymbal muscles for 10 species of cicada. In *a* and *b*, all the species have synchronous tymbal muscles except for *Platypleura capitata*, which is asynchronous. The lines are least-squares regression lines for the data, excluding *P. capitata* ($r = 0.95$ in *a* and *b*). In *a*, the unlabelled points represent the following species, in order of increasing twitch duration: *Psaltoda harrisii, Psaltoda argentata, Magicicada cassini, Magicicada septendecim, Cyclochila australasiae, Abricta curvicosta, Chlorocysta viridis* and *Cystosoma saundersii*. Details of these species are presented elsewhere[10,11]. Two species (*Arunta perulata* and *Tamasa tristigma*), in which there is some doubt about the cycle period during calling, are not included in this graph. In *b*, the unlabelled points represent the following species, in order of increasing twitch duration: *P. harrisii, P. argentata, T. tristigma, C. australasiae, A. curvicosta, A. perulata, C. viridis* and *C. saundersii*. Details of tymbal muscle fine structure for these species will be published elsewhere (R.K.J. and D.Y., in preparation). Data for *P. capitata* are given in ref. 11. *M. cassini* and *M. septendecim* were not included in the study of fine structure.

in asynchronous muscles are achieved by elaboration of stretch activation/release inactivation in muscles that basically have twitches of long duration[12,13].

Synchronous and asynchronous muscles can be distinguished by their fine structure, as Smith[1] points out; the former possess an extensive sarcoplasmic reticulum and T-system and tend to have small myofibrils, whereas the latter tend to have a very reduced sarcoplasmic reticulum and large myofibrils. In cicadas, twitch duration in synchronous tymbal muscles is inversely related to the quantity of sarcoplasmic reticulum within each muscle fibre (R.K.J. and D.Y., in preparation). The faster tymbal muscles also have smaller myofibrils, with myofibril cross-sectional area being the best morphological predictor of twitch duration (Fig. 1*b*). The asynchronous muscle of *P. capitata* is quite different from fast, synchronous muscle (for example, that of *P. claripennis*) in having a large fibril area and in being sparsely supplied with sarcoplasmic reticulum[11].

Thus, synchronous tymbal muscles constitute a graded series, throughout which contraction kinetics and fine structure are closely correlated with the normal operating frequency. We have demonstrated that contraction frequencies of over 200 Hz are achieved within the synchronous mode of operation. Clearly, 100 Hz is not the upper limit of contraction frequency in synchronous muscles.

Encephalization in *Proconsul africanus*

WALKER *et al.*[1] recently suggested that the Miocene hominoid *Proconsul africanus* was more encephalized than extant monkeys of similar body size, and they suspected that it may resemble pongids in relative brain size. As an index of encephalization they used an encephalization quotient (EQ) based on a particular allometric equation[2]. Here I re-examine the degree of encephalization of *P. africanus* by applying two additional, but different, indices of encephalization traditionally used in brain–body size studies: one based on the constant of cephalization (CC)[3–5], the other on the extra neurone index (N_c)[6]. Both approaches yield the same result, which is in conflict with that of Walker *et al.* According to these methods, the degree of encephalization of *P. africanus* is within the range of extant monkeys and substantially below that of the apes.

Table 1 Encephalization indices in *Proconsul africanus* and extant apes and monkeys

	EQ	CC	N_c ($\times 10^9$ neurones)
Proconsul africanus	48.8	19.6	1.9
Pan troglodytes	41.1	35.6	3.6
Pongo pygmaeus	31.6	30.1	3.3
Gorilla gorilla	17.2	31.2	3.5
Cercopithecoidea	22.9–82.0	8.0–20.2	0.9–2.1

EQ = brain weight (g)/0.0991 (body weight, g)$^{0.76237}$; CC = brain weight (g)/(body weight, g)$^{0.23}$; for calculation of N_c, see ref. 6.

The equation used by Walker *et al.* provides an excellent fit for brain–body size relationships in high-level taxa such as the class Mammalia (mouse–elephant curve) or the order Primates (mouse lemur–gorilla curve). Because of its high exponent of allometry (0.76), however, it tends to overestimate the degree of encephalization for small-sized species while underestimating encephalization in larger species, when comparisons are made at a lower level of the hierarchy. This is the case because among closely related species or genera, brain weight scales at a much lower power of body weight with values of the exponent of allometry characteristically falling between 0.2 and 0.3 (refs 3, 4, 7, 8). In the study by Walker *et al.* this phenomenon leads to obviously erroneous results such as gorillas being less encephalized than the least encephalized monkey and the range for monkeys surpassing that of the apes at the upper end by a considerable margin (Table 1). Being aware of the strong limitations of their method, Walker *et al.* resort to a comparison of *P. africanus* with similar sized monkeys. While this alleviates the problem somewhat, the fact that the comparison of EQs is based on an equation fitting high-level taxa still leaves a major source of error.

Using the same brain–body size data but an equation based on an exponent of allometry (0.23) consistent with brain–body size relationships among low-level taxa, yields not only different but much more consistent results (Table 1). The CC values for the apes are closely grouped together and substantially above the range for monkeys. *P. africanus* lies towards the upper end of the monkey range. For *P. africanus* to be at the bottom of the range of apes (CC = 30) would require a cranial capacity of 255 cm^3, almost 90 cm^3 larger than the actual estimate, at a body weight estimate of 11 kg. Use of the extra neurone index yields the same results (Table 1): apes fall closely together and are clearly above the monkey range with *P. africanus* in the upper end of the latter.

Thus, while *P. africanus* may share several derived traits with extant apes, relative brain size does not seem to be one of them.

SMITH AND WALKER REPLY—Leutenegger's discussion and data are a useful addition to the interpretation of relative brain size in *Proconsul africanus*, but careful evaluation of his data confirms our conclusion that *P. africanus* shows a tendency towards the increased encephalization that characterizes apes in comparison with monkeys. The indices used by Leutenegger do not eliminate the confounding effect of size that he correctly noted exists for the values that we reported when using a slope of 0.76 to calculate encephalization quotients.

While our measurement of relative brain size involved an inverse bias—animals with larger body weights having lower EQs—both indices used by Leutenegger show the opposite bias—larger animals having larger values. He reports Hemmer's[1] values for the constant of cephalization (CC) as being in the range 8.0–20.2 for Cercopithecoidea. The value of 8.0 is for the smallest cercopithecoid, *Miopithecus talapoin*, and the largest

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

values are for several of the largest species in the group, all from the genus *Papio*. With the extra neurone index (N_e), Jerison[2] reported that elephants have a value twice that of humans and porpoises have about the same values as we do. At the other end of the scale, the small South American squirrel monkey, *Saimiri sciureus*, was grouped with lemurs and marmosets rather than with more closely related, but larger, New World monkeys. Jerison himself noted that "If we demand that the values of N_e correspond to an ordering in terms of behavioural capacities we must assume either that the assumptions used in determining N_e are insufficient or that we grossly underestimate the behavioural capacities of the elephant and porpoise. I would guess that both types of error occur, but I would prefer, for the present, to emphasize the second."

If, as these results suggest, there is a tendency for CC and N_e to be underestimated for small species within a taxon, our suspicions of increased encephalization in *P. africanus* remain plausible. For both CC and N_e, the values for *P. africanus* listed by Leutenegger are close to the highest values for all monkeys and the monkeys with the higher values are also considerably larger than *P. africanus* in body size. *P. africanus* has lower values than the extant great apes, but also has a much smaller body size than these.

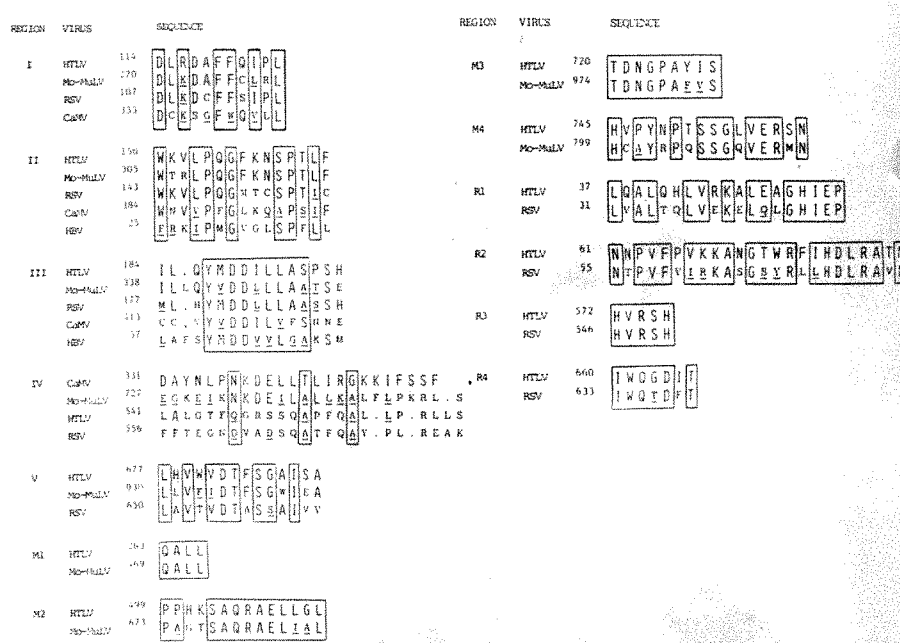
RECENTLY Toh *et al.*[1] reported the existence of amino acid sequence similarity between the reverse transcriptase of certain retroviruses and the DNA polymerases of cauliflower mosaic virus (CaMV) as well as a region of hepatitis B virus (HBV) that probably encodes a DNA polymerase. For completeness, we draw attention to other regions of protein similarity between retroviruses (human T-cell leukaemia virus, HTLV; Moloney murine leukaemia virus, Mo-MuLV; and Rous sarcoma virus, RSV), HBV and CaMV that were not reported by Toh *et al.*



The sequences are presented in Table 1 and the relative positions of the similar regions indicated in Fig. 1. The common set of amino acids discussed by Toh *et al.* is conserved in the amino-terminal region of all retrovirus reverse transcriptases studied (regions I–III). These common sequences are located near the amino-terminus of the HBV protein and the centre of the CaMV polymerase. Another region of similarity, IV, not discussed by Toh *et al.*, is also found in all retroviruses and is present in the CaMV protein. Region V, reported by Toh *et al.*, to be present in Mo-MuLV and RSV, is also found on HTLV. We also draw attention to sets of amino acids that are conserved with respect to sequence and relative position between the reverse transcriptases of HTLV and Mo-MuLV (M1–M4) and HTLV and RSV (R1–R4).

Two New Titles in Genetics from Cold Spring Harbor Laboratory

GENETIC MAPS

A Compilation of Linkage and Restriction Maps of Genetically Studied Organisms

Edited by Stephen J. O'Brien, *Laboratory of Viral Carcinogenesis, National Cancer Institute*

Completely updated and expanded, this 1984 edition of GENETIC MAPS contains 85 maps and covers 75 organisms. It includes linkage maps of all genetically studied organisms as well as restriction maps of the major bacterial and animal viruses, including lambda, T4, adenoviruses, SV40, and all retroviruses.

The only collection of its kind, GENETIC MAPS is an indispensible handbook for anyone involved in genetics whether researcher or student.

Primatology by numbers

Bernard Wood

The Order of Man: A Biomathematical Anatomy of the Primates. By Charles Oxnard. *Yale University Press: 1984. Pp.366. $30, £20.*

THE manner of acquiring knowledge about ourselves and our closest relatives, the primates, perceptibly changes every few years, so that the past two or three decades have witnessed the virtual transformation of primatology. Prior to this, apart from observations of captive animals and a few pioneering field studies, primatology was all but confined to classical comparative anatomical and palaeontological research. Primatology, or more accurately primate evolutionary biology, has now matured into a discipline which embraces studies as disparate as molecular evolution, ethology and comparative neurobiology.

Nonetheless, investigations of the form of the skeleton, and comparisons of homologous skeletal parts, still play a prominent part in primate studies. The advent of computers, along with statistical techniques which allow several variables to be considered simultaneously, have progressively added to the power and range of these so-called morphometric methods, and this book is the most recent of a trilogy* by Charles Oxnard which describes the basis, application, evolution and impact of the newer morphometric techniques. *The Order of Man* is particularly interesting because, more than either of the other books, it attempts to set these studies within the broader context of primatology.

Morphometry is the reduction of a complex form, usually a bone, to numbers. Present-day techniques are sophisticated in three respects. The first is the ingenuity of the ways in which shape and size are recorded: simple linear measurements are being superseded by three-dimensional coordinate and orthogonal analysis, as well as by optical techniques. The second is the application of morphometry to the internal structure of bone, thus increasing the comparative information which can be gleaned from skeletal material. Finally, there is the statistical treatment of the data. Multivariate techniques have been refined and elaborated so that the elements of a complex three-dimensional shape can be visualized and more easily compared with other homologous patterns.

In the United Kingdom, it was the Birmingham School of anatomists, led and inspired by the now Lord Zuckerman, who, in the post-War period, brought bivariate, and then multivariate statistics to the study of the skeletons of living and fossil primates. Claims for the recognition of new and different sorts of hominids were often, and sometimes correctly, based on morphological features; but, with some honourable exceptions, little attempt was made to support these decisions with quantitative data. To those unfamiliar with the morphology of such material it was easy, but unfair, to interpret all this work as unsound. Nonetheless, even when data could be assessed metrically, Zuckerman and his statistical collaborators saw the flaw in methods which implied that each measurement provided a separate "proof" of difference or affinity. They pioneered the introduction and use of simple statistical tests, and later used multivariate methods which were able to identify, and allow for, correlation and covariance between measurements. This work was continued by E.H. Ashton and Oxnard, who represent the first and second generations of the Birmingham School. Though much of their work has been collaborative, Oxnard has emerged as the spokesman, and indeed the doyen, of primate morphometry. So this book doubles as a statement of personal scientific philosophy, as well as being a prospectus for the morphometric cause.

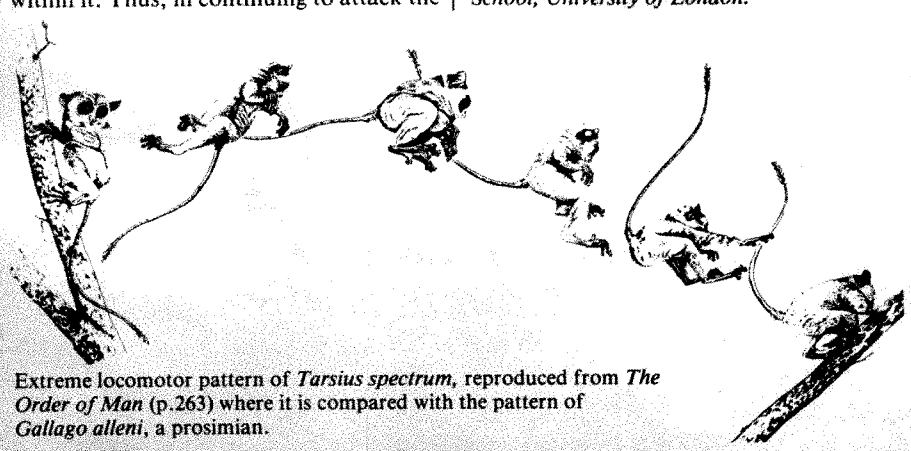
Morphometry has two main applications in primatology — the analysis of form in terms of, first, function and, second, affinity. As I understand it, the gist of the first application, as it has been applied to locomotion, is the following. Individual primate taxa show a range of locomotor and positional behaviours. Thus, the skeleton has to tolerate a range of imposed stresses and strains. These methods seek to find out whether some activities — leaping and hanging, for example — impose such constraints on skeletal variation (or vice versa) that the activity can be recognized in the bones. The second application, the essentially phenetic comparison of form, has found most use in the study of fossils, particularly fossil hominids. All fossils, like living individuals, are unique, but the problem is how to assess the significance of the differences between them. If they are greater than the variation in analogous modern taxa, or are qualitatively different from those seen in intraspecific variation, then taxonomic distinction is warranted. Morphometry provides the means to make these comparisons and assessments.

Most of *The Order of Man* is taken up with describing a series of case studies in which morphometry has been applied to various regions of the skeleton. The detractors of multivariate methods will claim that what these studies have revealed is evident to an experienced anatomist, but this is altogether too glib an assessment. By untangling the web of intercorrelation, such methods reveal patterns of association otherwise concealed from conventional analysis, and some studies, particularly those on the scapula and the pelvis, have provided important functional insights. However, perhaps more interesting than the results themselves is the way that Oxnard regards them. He apparently no longer sees these techniques as part of the armamentarium of the primatologist, but instead regards morphometry as one of three, seemingly discrete, approaches which can be used to determine relationships among primates (the other two being classical morphology and molecular evidence). Oxnard appears to see these technique-based divisions as somehow being in competition, and he points to the concordance of patterns shown by the molecular and morphometric techniques as evidence of the efficacy of the latter.

Apart from the dubious logic of such tests, the examples of concordance which are quoted are not as reliable as is implied in the text. For example the apparent agreement between morphometric and molecular evidence, that *Tarsius* is the sister group of the anthropoids, is contrasted with the conclusions of classical studies which class it as a prosimian. However, the molecular evidence for *Tarsius* is at best equivocal, and there is cogent evidence from classical morphology to suggest that *Tarsius* should be included, with the anthropoidea, in the Haplorhini. These details apart, I am dismayed to see a holistic approach to primate studies abandoned in favour of a compartmentalized one. It neglects other important lines of evidence, behaviour for example, and it implies that the three broad approaches provide the same type of information. Although some multivariate techniques take account of within-group correlation, the raw material of morphometrics is phenetic data. While some — perhaps even most — of this data reflects patristic affinity, part of it is likely to reflect parallelism and convergence, and thus confound attempts to determine "true" relationships. This philosophical shift in the way Oxnard views the evidence of comparative morphometrics, towards regarding it as suitable grist for the primate systematic mill, is thus a major change. It is also one which runs counter to the emphasis in recent years, exemplified by cladistic methods, which stresses the importance of analysing the total form of an animal or a bone, to distinguish between characters which are shared with a wide range of taxa, and those which are unique to a set of taxa, or a single taxon.

The last part of the book concentrates almost exclusively on assessing affinities,

**Form and Pattern in Human Evolution* (1973); *Uniqueness and Diversity in Human Evolution: Morphometric Studies of Australopithecines* (1975). Both published by The University of Chicago Press.



particularly those of hominid fossils. Along with many other workers, Oxnard and his colleagues have used morphometric and other evidence to demonstrate convincingly that the australopithecines are different from both modern man and the extant apes; in short, that they are unique. This generalization has been accepted by most hominid palaeontologists, even though some specimens such as the foot (OH 8) from Olduvai are still the object of the palaeontological equivalent of hand-to-hand fighting. Oxnard is right to claim credit for contributing to this conclusion. But he is wrong to suggest that it was morphometric evidence alone which brought about the change.

There is, however, less agreement about the significance of this phenetic uniqueness. While Oxnard and his colleagues regard it as debarring both the robust and gracile australopithecines from an ancestral relationship to *Homo*, others see one, or both, of the gracile australopithecine taxa as potential ancestors of either the *Homo* or robust australopithecine clades, or perhaps both. The former position would be vindicated if a more suitable *Homo* ancestor were to be found which was either synchronic with, or older than, the australopithecines. Oxnard makes this prediction explicit in the book, so it is particularly puzzling that he includes a *nota bene* section which draws attention to the generally "ape-like" morphology of *Australopithecus afarensis*. If anything, current interpretations of this earlier form of gracile australopithecine tend to emphasize the relatively *Homo*-like features of *A. africanus*, and it is by no means certain that, despite its "morphometric" uniqueness, it can be excluded as a common ancestor of both *Homo* and the robust australopithecines. It is simply not true, nor has it been for a decade or more, to say that patterns of human evolution in the literature "all conform to the notion of a single lineage". Since the abandonment of the "single-species" hypothesis most, if not all, hominid phylogenetic trees have incorporated a separate robust australopithecine lineage, and the recent schemes of Johanson, White and Kimbel incorporate the gracile australopithecines within it. Thus, in continuing to attack the unilinear evolutionary model, Oxnard spends most of the concluding chapter delivering a *coup de grace* to an opponent that has long since left the field. Oxnard is not familiar with the fossil evidence, and it shows throughout this section.

The design of the book and style of the text deserve comment, for they reflect Charles Oxnard's laudable desire to innovate. The layout is pleasing to the eye, but at times infuriating for the reader. Many figures are three or four pages away from the relevant text, and one is eight pages adrift. Despite the desire expressed in the preface that *The Order of Man* should be accessible to the beginner and the lay-person, and the inclusion of an abstract and a summary for each chapter, this is clearly not a book for the non-specialist. Nobody is better at explaining these difficult techniques than Oxnard, and indeed the early chapters discuss some general methodological problems with commendable conciseness and clarity. But most of the book is made up of highly technical diagrams, and the text takes for granted a considerable grasp of primate taxonomy and of systematics on the part of the reader.

The Order of Man is not merely a compilation of the published work of the descendants of the Birmingham School, yet neither is it an objective or comprehensive review of the contribution of morphometrics to primate studies. There is a dearth of self-criticism, and perhaps a surfeit of self-congratulation. It is as if the author were so impatient of the assessments of others, or so exasperated by the lukewarm response of his peers to published analyses, that he decided to act as his own judge and jury. Oxnard and his colleagues have offered much to current debates in primatology, but this text makes it no easier to understand where they are bound, apart from the prospect of mega-computations based on data from both limbs and trunk combined. I fancy that in the decades ahead this unusual book will be of as much interest to historians of science as it will to primatologists. □

Bernard Wood is Courtauld Professor of Anatomy at The Middlesex Hospital Medical School, University of London.

Extreme locomotor pattern of *Tarsius spectrum*, reproduced from *The Order of Man* (p.263) where it is compared with the pattern of *Gallago alleni*, a prosimian.

Vandalized space

Ian G. Halliday

Quarks, Gluons and Lattices.
By M. Creutz.
Cambridge University Press: 1983.
Pp.169. £17.50, $34.50.

RELATIVISTIC quantum field theory poses some of the hardest and most intriguing problems known to theoretical physicists. On the one hand the divergent perturbation series of quantum electrodynamics correctly predicts the magnetic moment of the electron to eleven significant places. On the other hand the experimentalists insist that protons are made of quarks, which refuse to behave as naive analogues of the proton and neutron in the nucleus or of the electron and proton in the hydrogen atom. No matter how hard one bangs protons together no quarks come out. Yet starting from a Hamiltonian written in terms of quark and spin coloured gluon fields, any application of perturbation theory would give free quarks.

So, theoretical physicists have been forced to alternative non-perturbative approximation schemes. The most popular is, at first sight, the most unlikely. Space-time is vandalized and reduced to a discrete, finite volume lattice. This kills all the sacred cows of translation invariance, Lorentz invariance and rotation invariance. We are off to a bad start. However, the system now consists of a finite number of degrees of freedom. Thus it is amenable to direct numerical simulation. Also, it is now very like a solid-state problem where much intuition has been accumulated. For example, near a second-order phase transition the correlation length or inverse mass goes to infinity and details of the lattice are washed out. This is the route to recovering Lorentz invariance! The limit must be taken in parameter space to a point where the correlation length becomes infinite in lattice spacings. This is equivalent to the lattice spacing tending to zero as required to recover the original field theory.

The purpose of Mike Creutz's elegant book is to provide a gentle introduction to the basic results in lattice field theory. It succeeds admirably. Without drowning the reader in detail, sufficient background is given to make the book very readable and provide an easy route to the research literature. Enough examples of calculations are given to develop real confidence in manipulating gauge groups, group integrals, duality and all the other tools of the trade. I recommend the book in the strongest terms to all interested in the fundamental structure of nature and the surprises quantum field theory has in store.

Ian G. Halliday is a Reader in Theoretical Physics at Imperial College, University of London.

Focus on fleas

Harry Hoogstraal

The Rothschild Collection of Fleas: The Ceratophyllidae.
By Robert Traub, Miriam Rothschild and John Haddow.
Published privately (distributed by Academic Press): 1983. Pp.494. £60, $99.

WE have here a contradiction to the statement: "No great and enduring volume can ever be written on the fleas, though many there be who have tried it" (H. Melville in *Moby Dick*, Chapter 104). Preceded by five volumes of the *Illustrated Catalogue of Fleas (Siphonaptera) in the British Museum (Natural History)*, this review of the Ceratophyllidae has been particularly difficult and time-consuming to prepare. Since 1936, when the last critical review of the family was published, the number of component species has increased from 71 to about 470 in 65 genera and subgenera, or about 20% of all known fleas.

As in the previous volumes, the specimens in the Rothschild and British Museum collections are listed. However, because of the sheer number of ceratophyllid species, the format of this volume differs from that of the first five. The keys (by F.G.A.M. Smit) to genera and subgenera (seven genera and eight subgenera are described as new) are preceded by a detailed account of morphology and a table of comparative morphology of the closely related family Leptopsyllidae, and are illustrated by 205 line-drawings and 90 photomicrographs (by J. Navarro and R. Traub) of definitive structures of each genus.

The sections on zoogeography and distribution, and the notes on hosts, include comments on the ecology of each ceratophyllid species. A distribution map accompanies the introductory remarks for each genus. The 151 full-page maps show collecting localities of each species on a background of the distribution of the chief host — a formidable task for much of the world, when dealing with so many different flea and host species from so many remote localities.

The review of hosts of ceratophyllids is a classic exposition of host–parasite relationships, special reference being made to the historical distribution of the chief hosts (especially the more-recently evolved Sciuridae, Cricetidae, Geomyidae; and certain birds). It appears to me that the nesting types of many important avian hosts (woodpeckers, swallows, weaver birds, buntings and so on) of ceratophyllids may have a significant role in their infestations by these fleas. The reasoning ("negative evidence") for the dearth of ceratophyllids on Muridae, other rodents and mammals of other orders is as important for biologists to understand as the reasons advanced for why ceratophyllids parasitize their chief mammalian hosts.

This section leads on to an equally valuable account of the evolution of the Ceratophyllidae from the standpoints of historical biogeography and host-relationships, morphology, taxonomy, phylogeny, physiology, behaviour and geological age. The conclusions are that these fleas, like their major and aboriginal hosts (Sciuridae), arose in the Nearctic Region about 30–40 million years ago (early Oligocene) and that they are also the most recently evolved and highly developed group of Siphonaptera.

In the chapter on medical importance, Traub stresses that ceratophyllids do not have a large role in the epidemiology of plague and murine typhus but are clearly important as vectors of zoonotic agents among small mammals, primarily rodents, which are the ultimate source of human disease. The introductory remarks on factors affecting epidemiology illustrate Traub's broad experience in the area of arthropod-borne diseases. Ceratophyllids are discussed in relation to plague, tularemia, other bacterial infections, rickettsiae, viruses, and other infections and medical aspects.

Three appendices complete the book, the first listing species described since 1975, the second dealing with the orders of hosts (and the number of families, genera and species in each) and the number of ceratophyllids (genera/subgenera) and other flea families associated with these host orders and families. Finally, Appendix 3 is an alphabetical list of host genera together with the major ceratophyllid species infesting each.

In the preface, the authors state that their aim was to provide a sound base for future work on this family of parasites and to assist the medical entomologist in the task of identifying his specimens. They have amply fulfilled their mission, and have contributed much solid data and conceptual wisdom to the biomedical sciences. □

Policy for science

Harvey Brooks

Science in Government: A Review of the Principles and Practice of Science Policy.
By J. Ronayne.
Edward Arnold: 1984. Pp.250.
Pbk £9.95, $19.95.

FOR the reader familiar with recent writings on science policy, there are few surprises or new insights in this book. However, it is an excellent and comprehensive review of a diverse and scattered literature — I know of no other book where this material has been brought together in such an organized and coherent way.

Ronayne interprets the term "science policy" as "policy for science"; there is little discussion of the use of science to inform political decisions about non-scientific issues — what is usually termed "science for policy". He deals with how national governments are or should be organized to support scientific research and development; the theory and practice of determining priorities among areas of research; the pervasive tensions between the claims of the scientific community for autonomy and the demands of society or the political system for accountability; the rationales for government intervention or non-intervention in the industrial innovation system; the role of science policy in fostering industrial innovation and economic growth, and the contribution of basic research to the economy; and the relative merits of centralized and decentralized (or pluralistic) approaches to science policy.

In the accountability versus autonomy debate, Ronayne concludes that society should determine the broad goals of research and areas of emphasis, while leaving questions of tactics and execution to the scientific community. On the question of scientific priorities, he is sceptical of the value of formalized analytical techniques of assessment, except possibly as an indirect stimulus to more systematic thought about opportunities and needs. He quotes with approval a University of Sussex dictum that "cost-benefit studies should not be undertaken...when the results may be taken seriously". Finally, on centralism versus pluralism, he seems to recommend a middle course, somewhat biased towards a semi-centralized position, in which "countries employ their scientists and technologists in a concerted manner to attack the problems that emerged in the new economic context".

Most of what is available in the literature consists either of advocacy or of multi-authored collections in which no attempt is made to contrast and analyse various perspectives. In addition to providing a comparative view, the book contains excellent descriptions of the government organization for science sponsorship and science policy in most of the major industrialized countries. It should thus provide a valuable textbook for an introductory course in science policy, and it deserves a wide audience. One unique feature is the first chapter, which presents a condensed history of the evolution of science policy from the beginnings of modern science in the seventeenth century; I found this the most original aspect of the book. □

MONASH UNIVERSITY
Melbourne, Australia
CHAIR OF EARTH SCIENCES

Applications are invited for the position of Professor and Chairman of the Department of Earth Sciences.

Earth Sciences is an active department which has rapidly gained an established national and international reputation for the high quality of its graduates and research. With nine academic staff and eight technical staff, it covers a wide range of interests, including structural geology, igneous, metamorphic and ore petrology/geochemistry, sedimentology, marine geology, palaeoclimatology, palaeontology, and regional geology and tectonics. A teaching and research program in geophysics begins in 1985 with the appointment of two academic staff. The postgraduate body includes six post-doctoral research workers and twenty-five PhD and MSc students.

The Department is well equipped for experimental and analytical studies and has strong field-based interests. It enjoys good relationships with industry and is involved in joint research projects. The Department has an excellent record of attracting research funds from Australian and overseas grant bodies.

An innovative earth scientist with a strong research reputation is sought to administer the Department and guide future development. The successful applicant must have outstanding leadership and administrative qualities, and the ability to interact positively with academics and industry. Applicants' interests should strengthen and/or complement existing teaching and research in Department. It is hoped that the new Chairman will take up duty in early 1985.

Enquiries about the Department may be directed to Dr Ian Nicholls, Deputy Chairman.

Salary: A$51,006 p.a. Superannuation, travel and removal allowance, and temporary housing assistance.

Information on application procedure and further particulars may be obtained from the Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.

Applications should reach the Registrar not later than 30 June 1984. Council reserves the right to make no appointment or to appoint by invitation at any stage.

An Equal Opportunity Employer.
(2023)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF BOTANY
ICI POST-DOCTORAL FELLOW

Applicants should have recently completed their PhD in bacteriology and/or mycology. A background knowledge of plant pathology and agriculture would be most desirable, and a clean car driving licence is essential. The project will run for two years, extendable for one further year, and will (1) develop biological control agents against soil-borne diseases and, (2) look for other agriculturally useful bacteria. The starting date is 1st July or as soon thereafter as possible.

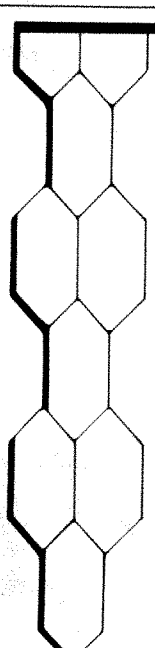
Applications, with two copies of curriculum vitae and the names of two referees, should be sent to Dr R Campbell, Department of Botany, University of Bristol, Woodland Road, Bristol BS8 1UG, England, by 31st May, 1984.

RESEARCH TECHNICIAN

Applications are also invited for the post of techician to work on the above project. Details and application procedure as above. (2051)A

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
BIOCHEMISTRY DEPARTMENT
CYTOGENETICIST

required for a leukaemia Research Fund supported project mapping human genes associated with chromosomal changes in leukaemias. Experience in cytogenetics is essential and an MSc or PhD are desirable. The post will provide the opportunity for a skilled cytogeneticist to learn some techniques of molecular genetics and recombinant DNA. The post is tenable for three years and is available immediately. The salary will be up to £8530 pa, depending on age, qualifications and experience, plus £1186 pa London Allowance.



Applications with curriculum vitae and the names of two academic referees should be sent to Mrs. J. Staight, Assistant College Secretary, Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH. Further details may be obtained from Dr. Susan Malcolm by telephoning 01-937 5411.

Closing date: 1st June 1984.
(2031)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
"NEW BLOOD" LECTURER IN MEDICAL VIROLOGY

Applications are invited from Science (PhD) or Medical graduates, aged less than 35 years, with a proven record in virological research. The Head of the Laboratory is Dr P D Griffiths (extension 3210) and current interests are herpes viruses, rapid diagnosis, immunosuppressed patients and cell-mediated immunity.

Medically qualified applicants: salary on scale £9,490 — £16,440 plus £807 London Weighting Allowance (with appropriate honorary clinical status at the Royal Free Hospital.) Non-medically qualified applicants: salary on scale £7,190 — £11,615 (under review) plus £1,186 London Weighting Allowance. Superannuation benefits. Eight copies of curriculum vitae and names of two referees to be sent by 8th June 1984 to the School Office, RFHSM, Rowland Hill Street, London NW3 2PF, (01-794 0500 ext 4262) from which further details may be obtained. (2018)A

Chemical Thermodynamicist

BP Research Centre is looking for a Chemical Thermodynamicist to join its team in Petroleum Engineering Branch investigating various aspects of the phase behaviour of hydrocarbon fluids. The post offered is for the study of transport properties of multicomponent fluids over a wide range of temperatures and pressures, including the critical region.

Candidates should possess a PhD in Chemical Thermodynamics and have experience in the experimental and theoretical study of transport properties and phase equilibria. Practical experience in computer programming and high pressure technology is essential.

An attractive remuneration package includes non-contributory pension scheme, subsidised restaurant, on-site sports and social facilities and relocation assistance where appropriate.

Please write, quoting reference SR.2432 to:
Mrs. Anne Hendry, The British Petroleum Company plc, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. (2056)A

BP Research
SUNBURY-ON-THAMES

SANDOZ RESEARCH INSTITUTE
Vienna, Austria

is one of three research centres of the Swiss-based international Pharma-group SANDOZ. Our task is the development of new pharmaceuticals for the prophylaxis and therapy of infectious diseases and cancer.

We are seeking a

TUMOUR IMMUNOLOGIST
(PhD or MD)

The successful candidate will study the influence of biological response modifiers on tumour growth and metastasis both in vitro and in animal models.

A minimum of two years postdoctoral experience in the field of tumour research and animal experimentation is expected.

Research facilities and working conditions are excellent. Salary will be negotiable, commensurate with experience and qualifications. Other benefits include a non-contributory pension plan and full reimbursement of moving expenses.

Please send application with curriculum vitae, a list of publications and the names of referees to

SANDOZ

SANDOZ Research Institute

(W989)A

NATIONAL MUSEUMS OF KENYA
DIRECTOR OF RESEARCH
INSTUTE OF PRIMATE RESEARCH (IPR)

The National Museums of Kenya invite applications from active research scientists with managerial experience for the post of Director of Research, IPR. The Institute has recently moved to a new facility, has a staff of 60 including 6 postdoctoral researchers and carries out studies in primate reproduction, tropical disease and conservation.

The Director of Research will be responsible for furthering the scientific reputation of the Institute, for attracting research grants (currently in excess of $300K per year), for maintaining research and training links with other agencies within Africa and internationally; and will wish to pursue his own research programme as well as managing the development of the Institute. Experience of successful research in developing countries would be an advantage.

The salary and conditions of service will reflect the importance of this post within the National Museums of Kenya. Applications, with detailed c.v. and the names of three referees, should be addressed to: R.E. Leakey, Chief Executive, National Museums of Kenya, PO Box 40658, Nairobi, Kenya, to arrive before 1 July 1984. (2016)A

Chisholm Institute of Technology
MELBOURNE, AUSTRALIA.

Dean
Faculty of Technology
(Ref. 84/38)

Applications are invited from suitably qualified persons for appointment as Dean, Faculty of Technology, Chisholm Institute of Technology. The appointee will be a member of the senior management team and will report to the Director.

Chisholm Institute of Technology is a multi-discipline post-secondary education institution offering a wide range of tertiary, specialist and continuing education courses on two campuses with an enrolment in advanced education courses in excess of 6,500. In January 1984 the Schools of Applied Science, Computing & Information Systems and Engineering were amalgamated to form a new Faculty of Technology which offers associate diploma, diploma, degree, post-graduate diploma and master's courses in a wide range of scientific and technological disciplines to approximately 2,100 students.

Applicants should preferably possess a higher degree, an outstanding record of achievement in academic and/or industrial research and development, together with a demonstrated ability to lead creatively the education and research activities of a multi-disciplinary Faculty.

It is expected that the appointee will be able to identify with the projected thrusts of the Faculty, provide academic leadership and foster and extend established links with professional associations, industry and government agencies.

The terms and conditions of appointment will be a matter for negotiation but it is envisaged that the successful applicant will be offered a five-year appointment at Head of School I, currently $A48,997 p.a. (to be supplemented by the recently approved National Wage Case 4.1% and the Academic Salaries Tribunal 5% salary increase). Other benefits are applicable.

A Position Specification is available from the Staff Branch, telephone (03) 573 2362.

Written applications, in duplicate, quoting the reference number, and including personal and career details, and the names and addresses of three referees, should reach the Staff Officer by 16 July, 1984. (W987)A

Caulfield Campus,
900 Dandenong Road, Caulfield East, 3145.
Victoria, Australia. Phone (03) 573 2222. 62674

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)
Keppel Street, WC1E 7HT

DEPARTMENT OF MEDICAL HELMINTHOLOGY

A "NEW BLOOD" LECTURESHIP

is available for a postdoctoral scientist under the age of 35 years to work on the genetic engineering of helminth antigens. Applications are invited from candidates with experience in gene cloning and/or immunology to lead studies on the genetic engineering of helminth antigens for defined antigen vaccines and immunodiagnosis, with particular emphasis on schistosomiasis and filariasis. The work is to be carried out in collaboration with the School's Wolfson Unit of Molecular Medical Microbiology and Parasitology, and will be an integral part of the research of well-established groups at the School studying the immunology of these infections.

Salary on appointment in the range £8,530 — £14,125 (under review) plus £1,186 London Weighting per annum, with normal superannuation benefits.

Applications, consisting of full curriculum vitae and naming two professional referees, should be sent to the School's Senior Assistant Secretary by 14 June 1984. (2039)A

SCOTTISH CROP RESEARCH INSTITUTE
Invergowrie,
Dundee DD2 5DA

HIGHER SCIENTIFIC OFFICER

A Plant Physiologist is required in the Department of Physiology and C_7 Production to join a group of physiologists studying growth and development of the potato at both crop and single plant level.

The appointee will investigate the carbohydrate balance of the growing tuber, factors affecting tuber dry matter content, and the influence of growing conditions and genotype on subsequent sugar accumulation during storage.

Qualifications: A first or upper second class honours degree with at least two years post qualifying relevant research experience which may be a course of research leading to a PhD degree.

Salary: £7,149-£9,561.

Non-contributory superannuation.

"The Institute is an equal opportunities employer".

Applications giving full details of age, education and experience together with the names of two referees should be lodged by 15 June, with Mrs J A Shepherd, the Personnel Officer of the Institute, from whom further details may also be obtained. (2053)A

RECOMBINANT DNA RESEARCH
Group Leader

Connaught Laboratories Limited is seeking a distinguished scientist to lead an active and growing team in the field of molecular genetics, oriented towards research into products of biological and medical signficance. The successful candidate will have extensive research experience and an outstanding publication record, demonstrating scientific creativity and a broad background in all aspects of molecular biology. Previous experience as a Group Leader, Project Leader or Principal Investigator is essential, while industrial experience is desirable but not essential.

Connaught Laboratories has been a major producer of biologicals for human and veterinary use for seventy years. Our research facilities are located in Toronto, Ontario. The Company offers a competitive salary and comprehensive benefits package including a bonus scheme, along with the opportunity to work in a stimulating, multidisciplinary research environment.

Curriculum vitae and names of three references should be sent in confidence to Dr Keith J. Dorrington, Vice-President, Research and Technology, Connaught Laboratories Ltd., 1755 Steeles Avenue West, Willowdale, Ontario, Canada M2R 3T4. (NW521)A

AN EQUAL OPPORTUNITY EMPLOYER

CONNAUGHT
where service complements research

UNIVERSITY OF LONDON

King's College London
Queen Elizabeth College
Chelsea College

'NEW BLOOD' LECTURESHIP IN PHYSICS

Applications are invited for an appointment from 1 October 1984 under the 'new blood' scheme in the research field of 'Inverse source problems in physics'. The successful candidate will contribute to research, already strongly represented in the Image Analysis Group led by Professor R E Burge, on inverse problems in scattering by electromagnetic and matter waves, eg, rough surfaces scattering, solution to the phase problem, super-resolution. The three Colleges are in the process of merging, and the Physics Department is being located on the Strand site of King's College.

Candidates should be less than 35 years of age on 1 October 1984 and must not currently hold a permanent university appointment in the United Kingdom. Salary on appropriate point on scale £7,190—£14,125 pa, plus London allowance of £1,186 pa.

Further particulars and application forms from the Secretary, Queen Elizabeth College, Campden Hill Road, London, W8 7AH. Tel 01-937 5411 ext 246. Closing date 4 June 1984. (2035)A

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

Applications are invited from physicists qualified to PhD level for appointment from 1 October 1984 or earlier by arrangement as

SENIOR RESEARCH ASSISTANT/SENIOR EXPERIMENTAL OFFICER

The successful applicant will join a team working on Very High Energy Gamma Ray Astronomy and will contribute to the construction, commissioning and deployment of a large telescope for the detection of 200GeV gamma rays using the ground-based atmospheric Cerenkov radiation technique.

The appointment would suit an experimental physicist/astronomer. Experience in electronics, computing or observational astronomy would be an advantage.

Salary will be on the 1A scale £7,190-£11,615 pa with superannuation and will involve working away from Durham for short periods.

Applications (3 copies) naming three referees should be sent by 15 June 1984 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE from whom further particulars may be obtained. (2057)A

GRADUATE ASSISTANT
Biochemistry/ Microscopy

The Friedrich Miescher-Institute has a vacancy for a graduate assistant to work on the development of microscopic methods for immunohistochemistry using monoclonal antibodies and in situ hybridization using cDNA probes. A good background in biochemistry is essential. Although familiarity with histochemical procedures is also desirable, training in microscopic techniques will be given where necessary. The Institute possesses excellent facilities for electron microscopy and allied techniques and the appointment also involves responsibility for their maintenance.

The position offers the possibility of long-term employment in a research environment with a minimum of routine work.

Applications, including cv, should be addressed to Dr A. Matus, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 Basel, Switzerland. (W990)A

POSTDOCTORAL POSITION (Research Associate) available to study the binding of amphiphilic environmental chemicals to biological and model membranes and the relationship of binding to membrane activity. Requires PhD in biochemistry or other area of relevant training. Research background in membranes, binding studies, and liposome preparation highly preferred. Salary range $15,500-$17,000. Send résumé and three letters of recommendation before June 15, 1984 to: Dr Terry L. Miller, Department of Agricultural Chemistry, Oregon State University, Corvallis, OR 97331. An Equal Opportunity/Affirmative Action Employer; complies with Section 504 of the Rehabilitation Act of 1973. (NW527)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

An SERC funded postdoctoral position to work on the mechanism of exocytosis in mast cells is available for one year from October 1984.

Salary will be in the range £8530-£10,710 according to age and experience.

Applications, including a curriculum vitae with list of publications should be made to Dr. J.C. Metcalfe at the Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge CB2 1QW. (2046)A

THE UNIVERSITY OF ASTON IN BIRMINGHAM

FACULTY OF LIFE & HEALTH SCIENCES

Applications are invited for the following appointments which have been awarded by the University Grants Committee as part of its 'New Blood' initiative.

Department of Ophthalmic Optics

"NEW BLOOD" LECTURESHIP

(Ref: 605/6)

A vision scientist is required to join a multi-disciplinary team of researchers in the Clinical Neurophysiology Unit. The appointee will work on theoretical, physiological and pathological aspects of eye-movements and will also contribute to the Undergraduate Honours Degree Course in Ophthalmic Optics.

The Department is seeking a young person of exceptional promise. The ideal candidate will have a record of significant publications and the ability to work in a creative group of colleagues on research, teaching and the development of new techniques for clinical investigation.

Department of Pharmacy

"NEW BLOOD" LECTURESHIP IN ADVANCED DRUG-DELIVERY SYSTEM DESIGN (Ref: 606/6)

We seek to attract a young person of exceptional promise at present working in any of the basic or pharmaceutical sciences and motivated to make an original contribution within the area of advanced drug-delivery system design.

The successful candidate will be expected to collaborate with members of the Drug Development Research Group and to initiate new research projects on the design of drug-delivery systems appropriate for the novel molecules and therapeutic strategies engendered by recent advances in molecular biology and genetic technology.

The department proposes to co-ordinate its research activities within a Research Institute framework and concentrate its efforts in innovative and commercially relevant projects. The annual recurrent research budget of the Department from external sources is in excess of £600 K and considerable resources will be mobilised to support the new post.

The appointments will be for a period of three years initially, with the possibility of renewal or subsequent transfer to a continuing appointment. Initial salary will be within and up to the maximum of the range £7,190 to £14,125 per annum.

Application forms and further particulars may be obtained from: **The Staff Officer (quoting the appropriate reference number), University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. Tel: 021-359 3611 Ext. 4564.**

Closing date for the receipt of applications is 15th June, 1984 (2062)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL PHYSICS & BIO-ENGINEERING

'NEW BLOOD' LECTURESHIP FOR MEDICAL IMAGING (NMR)

Applicants invited to join internationally known NMR Imaging Team of 11 total (8 MRC supported) led by Professor Mallard, Dr J M S Hutchison and Dr M Foster. The successful applicant will be particularly concerned with developing techniques for the detection and localisation of atheroma and the imaging of materials containing fluorine; also join in teaching of medical imaging at all levels, including MSc.

Salary will be on the Lecturer scale £7,190-£14,125 per annum (under review) with appropriate placing.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 8 June 1984. (2013)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF GENETICS

POSTDOCTORAL POST

A Postdoctoral position is available in the Department of Genetics for 3 years from October 1984, to work with Dr Howard Jacobs on the Isolation and Characterisation of Nuclear-coded Mitochondrial Genes from Mammalian Cells. This research is funded by an MRC Project Grant, and salary will be at the appropriate point on Range 1A of the scales for Research and Analogous Staff, plus USS benefits.

Applicants should be familiar with somatic cell genetics and/or recombinant DNA techniques.

Applications, including full curriculum vitae and the names of two referees, should be sent to Dr H T Jacobs, Department of Genetics, University of Glasgow, Glasgow G12 8QQ before 31st May 1984.

In reply please quote Ref No 5242M. (1903)A

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW,
MIDDLESEX HA1 3UJ

POST-DOCTORAL FELLOW in MOLECULAR BIOLOGY

Applications are invited from science graduates for a three year post-doctoral position in the molecular medicine research group to work on the molecular basis of atherosclerosis. A minimum of 3 years' experience in molecular biology is essential.

Salary scales are related to those for University non-clinical academic staff and salary on appointment will depend on age and experience. Informal enquiries may be made to Dr. James Scott (Head of Research Group) on 01-864 5311 ext 2257.

Application forms and further details available from Miss J Cottam, Personnel Section, ext 2673 quoting reference 111/ 1/ 3981.

Closing date for applications 7th June 1984. (2015)A

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOCHEMISTRY
BIOMEDICAL NMR GROUP

GRADUATE RESEARCH ASSISTANT
(REF: BT 104)

Applications are invited from graduates in electronic engineering, physics or allied subjects for the above post. The research, funded for four years by a programme grant, is concerned with biochemical and clinical investigations using NMR spectroscopy. The multi-disciplinary group, under the direction of Dr G K Radda, FRS, is located in the Department of Biochemistry and in the medical Facility at the John Radcliffe Hospital. The successful candidate will be expected to participate in developing NMR spectroscopy and imaging techniques for human studies.

Salary: on the scale £6310-£8530.

Applications: Including names and addresses of two referees, not later than the 9th June 1984 to: The Administrator, The Department of Biochemistry, University of Oxford, South Parks Road, Oxford OX1 3QU.

(2026)A

UNIVERSITY OF WYOMING

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL POSITION

available for two (2) years to study either the biochemistry of human mixed cryoimmunoglobulins or the spatial relationships among crystallins in the mammalian lens. Experimental approaches include spectroscopy (fluorescence energy transfer, CD, photoacoustic FTIR), differential scanning calorimetry and chemical crosslinking. No previous experience in these areas is necessary but an interest in applying physical approaches to biomedical problems is essential.

Please send CV and have three (3) letters of reference forwarded to: Dr. Russ Middaugh, Department of Biochemistry, University of Wyoming, Box 3944, University Station, Laramie, WY 82071, USA. Telephone: (307) 766-2273.

(NW529)A

BIRBECK COLLEGE
(University of London)

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH OFFICER IN PHOTOCHEMISTRY AND ENERGY TECHNOLOGY

Photochemistry will be used to probe the mechanism of free radical reactions in coals, with particular emphasis on novel processes for coal liquefaction. This SERC Research Officer post is available for two years from September 1984. Appointment will be made on scale £8080-£8530 pa (under review) plus £1186 pa London Weighting. Applicants should have a background in either organic photochemistry or coal chemistry. Applications in duplicate to include full CV and names and addresses of two referees should be sent to the Assistant Secretary (Personnel) (N) Birkbeck College, Malet Street, London WC1E 7HX. Further information can be obtained from Dr J R Darwent, Department of Chemistry (01-580 6622 ext 223). (2037)A

UNIVERSITY OF OXFORD

NUFFIELD DEPT OF CLINICAL MEDICINE

John Radcliffe Hospital

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post to join an existing team working on the elucidation of the molecular basis of Duchenne and Becker muscular dystrophies. The project is supported by the Muscular Dystrophy Group of Great Britain. Previous experience of DNA recombinant technology is desirable but not essential.

Salary: Research Staff 1A £7,190 — £11,615. Position available immediately. Application form and job description from: Departmental Administrator, Nuffield Dept of Clinical Medicine, Room 5801, John Radcliffe Hospital, Headington, Oxford OX3 9DU.

Closing date for applications: 1st June 1984. (2030)A

TRUDEAU INSTITUTE

A Postdoctoral research position in infectious disease

is currently available to study interactions between several intracellular microbial pathogens and the cellular defenses in both normal and immunosuppressed animals. Current research is directed towards understanding cellular interactions responsible for the modulation of delayed-type hypersensitivity and acquired antimicrobial resistance during the development of chronic systemic disease in inbred mice. Candidates should have a strong background in infection-immunity or in immunology.

The Trudeau Institute is a private, not-for-profit basic medical research institution situated on the shores of Lower Saranac Lake, about a mile from the village of Saranac Lake and 10 miles from Lake Placid, NY. On-campus housing is available. Salary is at appropriate NIH levels.

Send curriculum vitae and names of three references to: Dr Frank M. Collins, Trudeau Institute, P.O. Box 59 Saranac Lake, N.Y. 12983. An Equal Opportunity Employer.

(NW525)A

MIPCORP

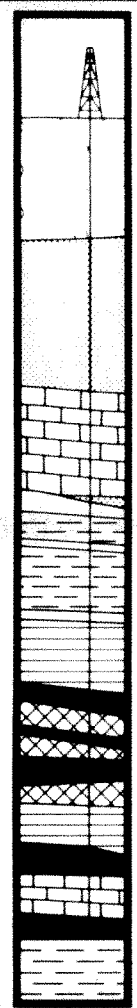
RESEARCH MANAGER

Cultivation of Algae. manage laboratory and field cultivation of spirulina algae; oversee research of new strains, conduct studies of growth rate and use of nutritionally important and other algae for mass culture/large scale algae ponds in Desert Hot Springs area. MS in Microbiology or Botany, and 4 years experience in culturing of algae required. $25,000/yr, 40/hrs/wk. Send résumé to MIPCORP, PO Box 867, Boulder Creek, CA 95006.

(NW528)A

UNIVERSITY COLLEGE LONDON

"New Blood" Lectureship



CELL BIOLOGY

Applications are invited for the above Lectureship in the Department of Experimental Pathology under the UGC's "New Blood" initiative. The post is available from 1 October 1984 and candidates should normally be aged 35 or under.

Applicants should be in the position of initiating and carrying out a research programme in the field of the transport and chemical processing of viral proteins within cells.

Salary in range £7,190-£14,125 per annum (under review) plus £1,186 per annum London Allowance.

Applications (no forms), including a full cv and names and addresses of two referees, should be sent to Assistant Secretary (Personnel), University College London, Gower Street, London, WC1E 6BT by no later than 8 June 1984. (2040)A

Stratigraphy Branch
BP Research Centre, Sunbury

Geologist – Computer Analyst

The Stratigraphy Branch of the Exploration and Production Division at the BP Research Centre in Sunbury requires a geologist with a strong and proven interest in computing. Applicants should have a first degree in geology and substantial experience of programming and using computers. Experience in the use and administration of data bases would be an advantage.

The successful applicant will work within the Computer Applications Section which currently supports two areas of work: palaeontology and stratigraphy. In the former area, the main computing project underway is the building of a palaeontology data base and associated applications programs for retrieval and graphical display of data. The principal stratigraphy computing project is the development of a linked data base — mapping system for the production of palaeoreconstructed maps with super-imposed geological information.

The present requirement is for a person with capabilities in two areas: data base administration and applications programming. The successful applicant will be responsible for maintaining the palaeontology data base and for maintaining links with other databases. A strong interest in the organisation and maintenance of large amounts of diverse data is therefore an essential prerequisite for the job. Additionally, the post holder will undertake applications programming tasks covering a range of disciplines within petroleum exploration geology.

The salary and benefits package reflects that of a major international business and includes a non-contributory pension scheme, subsidised restaurant and on-site sports and social facilities.

Please write, enclosing full curriculum vitae and quoting reference number STR 2617, to: Mrs. A. Hendry, BP Research Centre, Sunbury-on-Thames, Middx. TW16 7LN. (2054)A

BP Exploration Limited

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

MICROBIAL TECHNOLOGY LABORATORY

BASIC GRADE MICROBIOLOGIST

required to join a group of scientists studying the microbial sequestration of heavy metals and the microbial degradation of chlorinated organic compounds. The successful applicant should preferably have a PhD in microbiology or biochemistry.

The post is funded by a research contract from the Department of the Environment and is tenable until July 1986.

Salary will be in the range of £6277 — £8349.

National Health Service terms and conditions will apply.

Applicants should send a detailed curriculum vitae and the names of two academic referees to Mrs M. Bushby, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wiltshire SP4 0JG.

Closing date: 1 June 1984. (2041)A

RESEARCH SCIENTIST, to study the anion transport system in normal, fetal and malignant liver cells. Must have three (3) years experience in membranes and Immunology. Must have PhD in Biochemistry. Salary $19,000/yr. Job site in L.A., California. Send this ad and your resume to job no.4077, P.O. Box 865, Sacramento, CA 95804 no later than June 8, 1984. (NW538)A

UNIVERSITY OF CAMBBRIDGE

DEPARTMENT OF PHYSICS

POLYMER SCIENCE RESEARCH

It is wished to fill a vacancy from 1 October for a postdoctoral scientist with qualifications in physics, chemistry or materials science to work on a SERC supported research project applying TEM techniques to a range of problems in polymer science. Previous experience of research using transmission electron microscopy is desirable.

Salary range £7190 to £9425 p.a.

Applications should be addressed to Mr J Deakin, Cavendish Laboratory, Madingley Road, Cambridge CB3 OHE, by 16 June, quoting ref. AD. (2008)A

UNIVERSITY OF EDINBURGH

POSTDOCTORAL POSITIONS IN MOLECULAR BIOLOGY

Scientists with expertise in immunochemistry/hybridoma technology and gene manipulation are required to join a team engaged in identification and cloning of genes for clinically important antigens of a human malaria parasite.

Send cv and the names of two referees to: Dr J G Scaife, Department of Molecular Biology, Darwin Building, Edinburgh University, King's Buildings, Mayfield Road, Edinburgh EH9 3JR. (1974)A

PHOSPHOINOSITIDE METABOLISM: Postdoctoral position. Starting summer-fall 1984. Innovative, independent, recent PhD in biochemistry with experience in lipid chemistry preferred. Our laboratory has been investigating the involvement of PI metabolism in calcium gating. Minimum salary $16,000. Send résumé to: Dr S E Rittenhouse, Hematology Research MRB 216, Harvard Medical School, 75 Francis Street, Boston, MA 02115.

(NW532)A

CSIRO

AUSTRALIA

PHYSICIST

$A24,344-$A35,806

DIVISION OF TEXTILE PHYSICS

RYDE NSW

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Textile Physics is a member of the Institute of Industrial Technology.

FIELD: Fabric filtration.

GENERAL: The Division of Textile Physics has a program concerned with research into various aspects of the use of textiles for the filtration of dust from gas streams, especially flue gases in, eg, smelters and power stations.

DUTIES: As a member of the Fabric Filtration Group, undertake research on the relevant properties of textiles, the interaction of dust with the textiles, and adhesion of dust particles within the collected dust cake.

QUALIFICATIONS: A PhD degree or equivalent qualifications with major interest in applied physics and mathematics. Knowledge and experience in fields such as adhesion studies involving textiles or polymers in general would be an advantage.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Stating relevant personal and professional details, the names of at least two referees and quoting reference No A1167, should be directed to:

The Chief
CSIRO Division of Textile Physics
338 Blaxland Road
RYDE NSW 2112
AUSTRALIA

by June 15th, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W985)A

SOUTH AFRICA

Applications are invited from suitably qualified persons, regardless of sex, race, colour, or national origin for appointment to the following positions at the University of Witwatersrand, Johannesburg.

ASSOCIATE PROFESSOR/SENIOR LECTURER
Department of Genetics

Applicants should have a PhD in Genetics or an equivalent qualification in an appropriate related field such as Microbiology or Biochemistry together with a working knowledge of Genetics.

The successful candidate will be expected to teach topics in Prokaryotic Molecular Genetics and Genetics of Micro-organisms to third-year and Honours students and to undertake supervision of post-graduate students in these fields. A knowledge of recombinant DNA technology and an interest in the molecular genetics of higher plants will be a recommendation.

LECTURER
Department of Chemistry

Applicants should hold a PhD and have developed research interests at post-doctoral level in the general field of organic chemistry.

Salary level will be determined according to the qualifications and experience of the successful candidates and the ranges include a 12% pensionable allowance.*

Associate Professor:	R23,785 – R29,248 per annum.
Senior Lecturer:	R18,543 – R26,930 per annum.
Lecturer:	R14,178 – R24,834 per annum.

Benefits for elegible applicants include an annual bonus • pension • medical aid facilities • housing subsidy • remission of fees for dependants attending the University • travel assistance • removal costs • settling-in allowance.

A detailed information sheet can be obtained from Geof Henning, South African Universities Office, Chichester House, 278 High Holborn, London WC2V 7HE, quoting ref.1193 clearly on the envelope.

* £1 = R1.79 approx. (2044)A

UNIVERSITY OF THE WITWATERSRAND

POSTDOCTORAL POSITION IN LIQUID STRUCTURE RESEARCH

UNIVERSITY OF GUELPH

The liquid structure group in the Physics Department is seeking a Postdoctoral Research Fellow to work in the area of structure and dynazmics of gases and liquids. Current programs include measurements and simulation of the dynamics of dense noble gases and of Lorentz gas model systems, structural measurements on water and other molecular liquids, and the structure of water at the clay interface. As well as operating two neutron diffractometers at McMaster University and Chalk River Nuclear Laboratories, the group has an X-ray diffractometer and is pioneering the development of a liquids Gamma-ray diffractometer. Occasional trips to major facilities in the U.S. and Europe are also made. The applicant should have a rent PhD in experimental physics or chemistry or a related discipline and should be conversant in computer programming.

Please send applications, including resumé and names of at least two referees to: P A Egelstaff or A K Soper, Department of Physics, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (NW524)A

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY

'NEW BLOOD' LECTURESHIP

Applications for the above post are invited from candidates with experience in cardiovascular physiology and an interest in pursuing research relating to the control of cortical blood flow. Candidates wishing to visit the department or make preliminary enquiries should contact Professor A M Sillito (0222 44211 ext 2002).

Candidates should be less than 35 years old, and must not currently hold a permanent University appointment in the UK. Appointment to commence on the 1st October, 1984, and will be made at the appropriate point on the lecturer scale £7,190-£14,125 per annum.

Applications (3 copies), with curriculum vitae, together with the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College, PO Box 78, Cardiff CF1 1XL from whom further particulars my be obtained. Closing date 14th June, 1984. Ref: 2777. (2024)A

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place,
London W2 1PG

Applications are invited for the post of

LECTURER IN PHARMACOLOGY

The appointment calls for experience in the teaching of physiological and receptor pharmacology and the appointee would be expected to take immediate responsibility for the teaching of these areas within the pre-clinical course. An interest and experience in the application of computing techniques in both teaching and research is also desirable. The appointee will be expected to pursue a research programme in the general area of receptor pharmacology and also to develop BSc teaching options in this area.

Applications in duplicate in the form of a full cv with names and addresses of two referees should be sent to the Assistant Secretary (Personnel) at the above address by 1 June. (2032)A

UNIVERSITY COLLEGE LONDON

POSTDOCTORAL POSITION IN ELECTROPHYSIOLOGICAL ANALYSIS OF SYNAPTIC MECHANISMS

Applicants are invited for work on neurotransmitter-operated ion channels. At present this work involves mainly single ion channel recording from neuronal cells from peripheral autonomic ganglia, though other methods and other preparations may also be used. The laboratory has long term MRC support to David Colquhoun and Stuart G. Cull-Candy and is well equipped for this sort of work. Those who have applied for our recently advertised job in receptor reconstitution need not re-apply.

Please send applications to Professor D Colquhoun, Department of Pharmacology, University College London, Gower Street, London, WC1E 6BT. (2034)A

PLANT MOLECULAR GENETICS

A tenure-track position at Assistant/Associate Professor level is open immediately in the Genetics Department, NCSU. Position involves 70% research and 30% teaching. Individual expected to have strong training and expertise in molecular biology and to develop a high quality research program. Applications must be received by 15 July 1984. Send CV, statement of research and teaching interest and three letter of reference to: Dr John G Scandalios, Head, Department of Genetics, Box 7614, North Carolina State University, Raleigh, NC 27695-7614.

North Carolina State University is an affirmative action/equal opportunity employer. (NW534)A

MEDICAL RESEARCH COUNCIL SCIENTIST GRADE II Ref MS/5/84

Applications are invited for a short term non-clinical scientific post tenable for three years. Candidates of immediately post-doctoral status will be preferred. The appointee will work as a member of a group on an established project concerned with cytogenetic and molecular aspects of malignancy in cultured human B lymphoid cells. Experience in molecular biology will be an advantage but is not essential. Salary according to age and experience will be on MRC scales, and applications with the names of two referees should be forwarded to Mr A Douglas, Administrator, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh, EH4 2XU by 4th June 1984, quoting reference MS/5/84. (2019)A

OXFORD POLYTECHNIC

DEPARTMENT OF GEOLOGY AND PHYSICAL SCIENCES

TEMPORARY TECHNICIAL — GEOLOGY REF: S/18

Temporary technician required from August/September 1984 initially for one year with the probability of a further year. For the first year duties will include cataloguing and curating of geological specimens and preparation of laboratories for practical classes.

For the second year assistance would be required with the preparation of thin-sections for teaching, research and student projects. Appropriate qualifications in Geology (eg BTEC, HNC or Degree) and/or experience in the areas mentioned desirable.

Salary according to qualifications and experience in the range Scale 3/4:

Scale 3 £5640-£6135
Scale 4 £6264-£7005

Plus qualification allowance where appropriate.

Application forms and details available from the Staffing Department, ext 364. Closing date: 31.5.84.

Gipsy Lane, Headington, Oxford OX3 OBP. Telephone Oxford 64777. (2064)A

CENTRE FOR REPRODUCTIVE BIOLOGY, UNIVERSITY OF EDINBURGH

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

LECTURER IN REPRODUCTIVE BIOLOGY

Applications are invited from scientists under 35 years of age for the above post created under the New Blood Scheme. Persons already holding a permanent university appointment in the UK are not eligible. The successful applicant will be expected to undertake research related to the biology of gametes in collaboration with a team of scientists and clinicians involved with human in vitro fertilization. Teaching responsibilities include the supervision and training of PhD students and research fellows. There are excellent opportunities for collaborative research with other scientists in the centre.

The salary will be at an appropriate point on the scale £10,710-£14,125 per annum.

Further particulars can be obtained from Professor David T Baird, Department of Obstetrics and Gynaecology, University of Edinburgh, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh, EH3 9EW.

Applications (12 copies) including curriculum vitae and giving the names and addresses of two referees, should be sent to The Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL. By 30th June, 1984.

Please quote reference NB6 (84). (2049)A

TEMPLE UNIVERSITY OF MEDICINE DEPT. OF MICROBIOLOGY and IMMUNOLOGY — Applications are invited for two full time faculty positions (one at tenure track) at the Assistant or Associate professor level. We are searching for highly qualified individuals able to establish a productive independent research program. Candidates must have a Doctoral degree, extensive post-doctoral experience and publications in microbial genetics, molecular biology of host pathogen interactions or immunology. Successful candidates will also be members of the graduate faculty and will have responsibility for teaching both graduate and medical students. Currently the Department consists of 13 full time resident faculty members plus several joint and affiliated appointees, and operates active doctoral and post-doctoral programs. Numerous opportunities for interdisciplinary interactions and collaboration are available with individuals with mutual interest in the Department, the Institution, and the Philadelphia area. Send curriculum vitae and names of three references to Gerald D. Shockman, PhD, Chairman, Dept. of Microbiology and Immunology, Temple University School of Medicine, Philadelphia, PA 19140. Equal opportunity, affirmative action employer. (NW537)A

BIOTECHNOLOGY

Celltech is one of the World's leading specialist biotechnology companies. Based in the UK. The Company is backed by four major City of London financial institutions. A strong scientific team has now been built up in the areas of recombinant-DNA and cell-hybridisation and continued expansion is envisaged; close links are also maintained with the academic community. The Company aims to exploit the potential of discoveries arising in the field of biotechnology, and commercial successes have already been adhieved in several areas.

CHIEF TECHNICIAN — Immunology

Further expansion of Celltech's activities in areas of immunology including production of monoclonal antibodies as well as cell produced factors that regulate the immune response is planned. This gives rise to a position for a highly skilled Tissue Culture Technician with very wide experience in many tissue culture applications such as both primary cultures and cell lines.

This person will have responsibility for operation of a new tissue culture laboratory, supervision and training of personnel as well as collaborate with scientists on a wide variety of scientific problems using the facilities. The successful candidate should have at least fifteen years' experience of tissue culture including growing of a large number of different kinds of rodent and human cells, growth and assay of a wide variety of viruses, cell fusion technology, diagnostic assays, protein separation techniques and assays. A part of the research programme involves growing and cloning of different cells. The training of staff in all these areas is part of the responsibility of this position.

Since it is expected that Celltech will expand its laboratories, experience in design and setting up of similar tissue culture laboratories is essential.

Please quote reference number 202.

GROUP LEADER

We require a group Leader to run a section of several Tissue Culture Technicians who produce and assay monoclonal antibodies. Applicants should have at least 5 years' post-doctoral experience with a good grounding in immunology.

The successful applicant will be required to interact with other research groups inside and outside the company and with commercial divisions of the company and will also be expected to carry out bench work in addition to the above managerial duties.

Please quote reference number 203.

To apply, please send a full C.V. quoting the appropriate reference number to:-

Jane Walley, Personnel Officer, Celltech Limited, 244-250 Bath Road, Slough, Berkshire SL1 4DY.

CSIRO
AUSTRALIA
GLASSY METALS RESEARCH RESEARCH FELLOW
$A24,344-$A30,038
DIVISION OF APPLIED PHYSICS LINDFIELD NSW

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Applied Physics is a member of the Institute of Physical Sciences.

The Division, with a staff of nearly 400, undertakes research in applied physics related to problems in industry and community, and collaborates with industry in exploiting promising developments. Research includes programs in optics; electric, magnetic and thermal properties of materials; discharges in gases; and the measurement of temperature. The Division is also responsible for the maintenance of the Australian standards of physical measurement.

The Division wishes to appoint a Research Fellow under the Australian National Research Fellowship Scheme to work on the production, properties and uses of glassy metals.

Under the National Research Fellowship Scheme, preference is given to Australian citizens or residents.

DUTIES: The appointee will join an existing research program and will take part in research aimed at producing new glassy metals and investigating their properties.

QUALIFICATIONS: A PhD degree in physics, metallurgy, materials science or engineering, or equivalent qualifications, plus proven research ability.

TENURE: A term of 3 years. Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees, and quoting reference No M8668, should be directed to:

The Chief
CSIRO Division of Applied Physics

UNIVERSITY OF STIRLING

DEPARTMENT OF BIOLOGICAL SCIENCE

POSTDOCTORAL RESEARCH FELLOW

Applications are invited from candidates who have recently graduated or expect to graduate in the near future with a PhD Degree in Biochemical or Chemical Sciences. The post, for two years, is funded by a grant provided by the multiple sclerosis society to Dr. P.J. Brophy and Dr. A. Watts of Oxford University. Candidates should have some experience in one or more of the following areas: Membrane Biochemistry, Organic Synthesis or NMR Spectroscopy. The research will be on Lipid-Protein interactions in Myelin. Salary within IA Scale which starts £7,190 per annum. It is expected that the successful applicant will be based in Oxford University.

Applications, together with the names of two referees, should be sent to the University Secretary, University of Stirling, Stirling FK9 4LA by Friday 8 June 1984. (2045)A

POLYTECHNIC OF CENTRAL LONDON

Faculty of Engineering and Science
SCHOOL OF BIOTECHNOLOGY

TWO LECTURESHIPS IN MICROBIOLOGY AND BIOCHEMICAL/CHEMICAL INSTRUMENTATION (LII or SL)

Applications are invited from well qualified and experienced scientists for the above posts tenable from 1st September 1984 or as soon after as possible.

Salary scales (under review): Lecturer II £8,202-£12,555; Senior Lecturer £11,670-£13,539(BAR)-£14,430 per annum inclusive of London Allowance.

Further particulars and application forms from the Personnel Office, Polytechnic of Central London, 309 Regent Street, London W1R 8AL. Closing date: 1st June 1984. (2043)A

ROCHE

The **Clinical Pharmacology** group of the **DEPARTMENT OF CLINICAL RESEARCH** is responsible for investigation of the **pharmacodynamics** and **pharmacokinetics** of new drugs in humans.

To expand our small team, we are looking for a

PHYSICIAN

with training in clinical pharmacology (internal medicine, pharmacology), and an interest in working in research.

This interesting field of work includes the planning, conducting, and evaluation of clinical pharmacology studies of research compounds in phases I-IV.

Pre-requisites are a knowledge of the methods of assessing drug effects in man, and/or pharmacokinetics, as well as a good command of German and English.

Interested applicants are requested to send complete application documentation to our Personnel Department, quoting reference Nature 50/83.

Company, CH — 4002 Basle (W982)A

ROCHE

THE CHINESE UNIVERSITY OF HONG KONG

invites applications for the post of

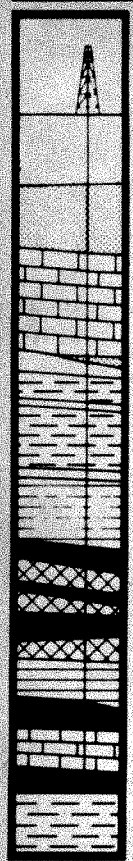
LECTURER IN BIOLOGY

The appointee, who should hold a doctoral degree, is expected to undertake research and teaching on aspects of Physiology/Morphogenesis for Higher Plants. He will be a member of the Board of Studies in Biology and will participate in the general teaching (including a general course on Plant Biology) and all other activities of that Board.

ANNUAL SALARY: HK$135,780 — 154,140 by 2 increments BAR HK$163,260 — 227,100 by 7 increments. Exchange rate approximately: US$1 = HK$7.8, £1 = HK$12. Starting salary and grade will depend on qualifications and experience.

CONDITIONS OF SERVICE: Benefits include sick leave, vacation leave, long leave with pay, superannuation (University 15%, appointee 5%), medical benefits, education allowance for children and housing allowance for those whose annual salary is HK$144,960 or above, and for appointees on overseas terms, passage benefits for themselves and their dependents as well.

APPLICATION PROCEDURE: Applications should be made out in duplicate, giving full particulars, experience and the names and addresses of 3 persons to whom reference may be made, and sent together with copies of certificates/diplomas/testimonials and recent publications to the Personnel Section, The Chinese University of Hong Kong, Shatin, N.T. Hong Kong not later than *July 31, 1984*. Please quote reference number 14/509/2/84 and mark 'Recruitment' on cover. (W992)A



KINGDOM OF SAUDI ARABIA
KING SAUD UNIVERSITY
COLLEGE OF AGRICULTURE
RIYADH, SAUDI ARABIA

Qualified personnel are invited to apply for the following posts of FACULTY MEMBERS (Professors, Associate Professors, Assistant Professors), LECTURERS, DEMONSTRATORS, RESEARCH ASSISTANTS and TECHNICIANS for the academic year 1984 -1985.

Department	Specialization	Qualification
I. Staff members:		
(1) Food Science	a. Human nutrition metabolism. b. Dairy technology. c. Food analysis.	Ph.D., Teaching experience, Arabic speaking.
(2) Animal Science	a. Poultry nutrition.	-do-
(3) Plant Production	a. Cytogenetics.	-do-
(4) Ag. Economics & Rural Sociology	a. Farm management. b. Marketing of agricultural products.	Ph.D., Teaching experience, Associate or Professors only, Arabic speaking.
(5) Home Economics & Nutrition (Female only)	a. Textiles and costumes.	Ph.D., Teaching experience, Arabic speaking.
II. Lecturers:		
(1) Home Economics and Nutrition (Female only)	a. Plant production (ornamentals) b. Plant production (field crops).	M.Sc., Teaching experience, Arabic speaking.
(2) Plant Production	a. Plant production (vegetable crops).	-do-
(3) Animal Production	a. Animal production	-do-
III. Demonstrators:		
(1) Food Science	a. Fish and meat technology. b. Food microbiology. c. Food analysis.	B.Sc. "B" average or higher, past experience in teaching, research is preferred, Arabic speaking.
(2) Plant Production	a. Horticulture (vegetable crops).	-do-
(3) Agricultural Engineering	a. Agric. Engineering.	do-
IV. Research Assistants:	a. Food microbiology. b. Food chemistry and analysis. c. Horticulture (Pomology). d. Field Crops (Breeding).	Preferably M.Sc. with research experience in the field of specialization.
V. Technicians:	a. Human nutrition. b. Cereal technology. c. Analytical chemistry in the field of food science.	Experience in field of work, conducting and operating laboratory equipment. Experience and training in operating food and nutrition analyses equipment preferably IR, AAA, AA, GLC, HPLC. Good knowledge of English language.

Please apply to:
Dean, College of Agriculture,
King Saud University,
P.O. Box 2460,
Riyadh 11451,
Kingdom of Saudi Arabia.

Stratigraphy Branch
BP Research Centre, Sunbury

Geologist/Geophysicist

The Stratigraphy Branch of the Exploration and Production Division at the BP Research Centre in Sunbury requires a geologist/geophysicist with strong and proven interests in structural geology, plate tectonics, reconstructing past continental positions, palaeomagnetism and computing. Applicants should have a PhD degree in Geology or Geophysics, preferably with post doctoral research or industrial experience.

The successful applicant will work with the Stratigraphic Projects Section, which is responsible for developing and maintaining BP's expertise in plate reconstruction and structural geology to evaluate motions of continents through time, to help understand placement and timing of structures, basin development, and sediment accumulation in relation to plate motions, and can assist in developing and maintaining a computerised and cartographic system for palaeoreconstruction and palaeogeographic mapping. The person appointed will work as a member of a multidisciplinary team, and will be expected to interact closely with members of other BP groups directly involved in different aspects of petroleum geology.

The salary and benefits package reflects that of a major international business and includes a non-contributory pension scheme, subsidised restaurant and on-site sports and social facilities.

Please write, enclosing a full curriculum vitae and quoting reference number STR 2616, to: Mrs. Anne Hendry, BP Research Centre, Sunbury-on-Thames, Middlesex TW16 7LN.

DEPARTMENT OF RADIOLOGY

POSTDOCTORAL RESEARCH
NMR APPLIED TO TISSUE METABOLISM

Two positions are available to pursue research in physiology and metabolism using the non-invasive method of high resolution nuclear magnetic resonance. The laboratory is currently investigating several aspects of cardiac and brain metabolism using NMR techniques. Research projects in both basic studies and in clinical applications are available. The facilities of the NMR Laboratory are extensive and state-of-the-art and include a one meter bore system under development for clinical use. The laboratory also has an excellent staff to support various aspects of the research. Candidates should have training in biochemistry or physiology. Additional experience in physical and analytical chemical methods is desirable but not essential.

Please send a résumé and three letters of reference to: Ray L. Nunnally, PhD, Director of Biomedical Magnetic Resonance, Department of Radiology, University of Texas Health Science Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas 75235.

Equal Opportunity University.

(NW530)A

The European Molecular Biology Laboratory, a research Institute situated in Heidelberg, West Germany, invites applicants for the following vacancy at the Laboratory's Outstation at the Deutsches Elektronensynchrotron (DESY) site in Hamburg.

BIOPHYSICIST/PHYSICAL BIOCHEMIST

The successful candidate will interest collaboratively with visiting groups using time resolved X-ray diffraction and scattering methods for the study of poorly ordered systems (fibres, solutions, gels). In addition, he/she will be responsible for the instruments for these experiments and be given an opportunity to carry out a limited in-house research project.

Applicants must have a PhD and experience with X-ray structural methods.
Experience in computing will be an asset.
Fluent knowledge of English and of one or more of the other official languages of the EMBL (French, German) is a prerequisite.

An above average salary will be offered to the successful candidate.
Certain allowances are payable in addition, depending on personal circumstances.
An initial contract of 3 years' duration, which can be renewed, will be offered.

Please write briefly for an application form quoting reference No 84/22 to: EMBL, Personnel Section, Postfach 10.2209, D-6900 Heidelberg

EMBL

(W991)A

Department of Biology
Cell Biologist

The University of Calgary invites applications for a 3-year limited term position at the Assistant Professor level in the Department of Biology. The successful candidate will be expected to develop an active research program in the area of cellular/molecular biology of microbial eukaryotes, to teach an undergraduate course in Cell Biology and to participate in Biotechnology and Molecular genetics laboratory teaching. Applicants must have post-doctoral experience and strong credentials in molecular biology. Preference will be given to those with experience in recombinant DNA techniques.

The appointment will be open as of January 1, 1985, with an expected starting salary in the range of $29,700 to $35,000 per annum, based on the 1983-84 scale.

In accordance with Canadian Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada.

Applicants are requested to submit a complete curriculum vitae, and to have three letters of academic reference forwarded, by September 1, 1984 to:

THE UNIVERSITY OF CALGARY

Dr. R.W. Davies
Department of Biology
The University of Calgary
2500 University Drive N.W.
Calgary, Alberta T2N 1N4

UNIVERSITY OF THE WEST INDIES

Mona, Jamaica

pplications are invited for the ollowing posts:

PROFESSOR OF PURE MATHEMATICS, MONA, JAMAICA

Applicants of suitable stature in any area will be considered. Duties to be assumed as soon as possible.

LECTURER/ASSISTANT LECTURER IN BIOCHEMISTRY, MONA

It is desirable for teaching purposes that the successful applicant should have broad training in Biochemistry. Certain areas of research interest are particularly welcome, eg Plant Biochemistry, Toxicology, Nutrition, Immunology, Biotechnology. Duties to be assumed as soon as possible.

ELECTRON MICROSCOPIST

DEPARTMENT OF BOTANY, MONA

Successful applicant will be required to take charge of the Electron Microscope Unit comprising transmission and scanning electron microscopes, to supervise the work in the Unit and help users of the microscopes, and to train a limited number of technicians in methods of electron microscopy. He/she may also be required to teach a short course in his/her speciality. Preference may be given to applicants with interest in Biological Sciences. Duties to be assumed as soon as possible.

Salary Scales: Professor in range $38,340 — 47,194. Lecturer (Non-Medical) & Electron Microscopist $23,688 × 768 — 28,296 (B) × 825 — 33,246. Assistant Lecturer (Non-Medical) J$20,379 × 717 — 21,813 £1 = J$5.35 at 1/5/84).

Up to five full passages (economy class) plus baggage allowance up to J$900 on appointment and normal termination. Special allowance up to J$300 for shipment of academic books and teaching/research equipment on appointment. Unfurnished accommodation at 10% of pensionable salary or optional housing allowance of 20% of pensionable salary. Pension provision. Subsidised Health Service. Annual Book Grant. Annual Study & Travel Grant for self, spouse and three children. Transportation allowance to persons who operate a motor vehicle.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status, and the names and addresses of three referees should be sent as soon as possible to the Registrar, UWI, Mona, Kingston 7, Jamaica. Applicants in the UK should also send one copy to the Assistant Secretary General (Appts), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. Further details obtainable from either source. (W993)A

NATIONAL INSTUTUTE OF AGRICULTURAL ENGINEERING

PHYSICIST/ RESEARCH ENGINEER

The NIAE is respected internationally as a major centre of agricultural engineering research and development. It is engaged in a wide range of research projects, and one of its teams is working to increase the efficiency of greenhouse crop production.

A graduate Physicist/Research Engineer is now required to join this team engaged initially in developing mathematical models to be used to optimise the design of future greenhouses of novel shape and carry out research into new cladding materials and heating systems.

The appointment calls for a candidate with a first or upper second class degree in Physics/Engineering who can combine sound engineering and scientific principles with creative and innovative design.

Salary will be in the range £6,018-£9,561 per annum depending on experience and there is a non-contributory pension scheme.

The NIAE is situated in the beautiful countryside surroundings of Wrest Park, Silsoe, midway between Bedford and Luton. There are excellent working conditions and facilities both in Wrest Park mansion itself and in the advanced, purpose-built research laboratories and workshops.

Further details and an application form can be obtained from the Personnel Officer, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Bedford MK45 8HS. Telephone: Silsoe (0525) 60000. Please quote ref 20/5. (2014)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHARMACOLOGY

WELLCOME LECTURESHIP IN VETERINARY PHARMACOLOGY

Applications are invited from veterinary graduates preferably of not more than 35 years of age, for the post of Wellcome Lecturer in Veterinary Pharmacology tenable for a period of up to five years in the Department of Pharmacology. Persons holding permanent university appointments in the U.K. are ineligible for consideration.

The successful applicant will contribute to the teaching of pharmacology to veterinary and science students and will be expected actively to pursue a research project.

Salary will be in the range £7,190-£14,125 per annum depending on age and experience.

Applications, together with the names of two referees and a summary (up to 500 words) of research to be pursued, should be received not later than 16th June 1984 by the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH, from whom further details may be obtained.

CSIRO
AUSTRALIA
CHIEF OF THE DIVISION
DIVISION OF WILDLIFE AND RANGELANDS RESEARCH
INSTITUTE OF BIOLOGICAL RESOURCES
CANBERRA ACT

Applications are invited for the position of Chief, Division of Wildlife and Rangelands Research, from scientists who have an outstanding record of personal research achievement and leadership in an appropriate field of biological science.

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists.

The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The Division of Wildlife and Rangelands Research is one of the Divisions of the Institute of Biological Resources. Also in the Institute are the Divisions of Entomology, Forest Research, Horticultural Research, the Centre for Irrigation Research, and the Divisions of Plant Industry, Soils, Tropical Crops and Pastures, and Water and Land Resources.

The Division of Wildlife and Rangelands Research has its headquarters in Canberra, ACT, and laboratories at Darwin and Alice Springs, Northern Territory; Deniliquin, New South Wales and Helena Valley, Western Australia. The total Divisional staff of 204 includes 52 research scientists and 26 other professional staff.

The Division studies the ecology of animal and plant populations and processes controlling their stability, diversity, productivity and value to Australia in relation to their management and conservation. The Division's interests cover a wide range of Australia's ecosystems. Amalgamation of the Wildlife and Rangelands groups in 1982 gives the Division a special interest in rangelands research.

A Chief of a Division is responsible for the leadership, development, scientific direction and integration of the Division's research programs, and is encouraged to promote active collaboration with other Divisions, research bodies and agencies working in associated areas.

The salary for the position of Chief is negotiable, but will not be less than $A55,050 per annum. In addition, the position attracts an expenses of office allowance $A1,250 per annum.

Appointment to the Organization is for an indefinite period and Australian Government superannuation benefits are available. The postion as Chief is offered for a negotiable term typically of five to seven years, with subsequent options for a further term, if mutually desired.

Further information on the Division and its research is contained in a booklet available on request from the Secretary (Personnel) or the Secretary, Institute of Biological Resources at the address below. Dr M G Pitman, OBE, ScD, FAA, Director of the Institute of Biological Resources would be pleased to discuss the position with potential applicants. He would also be pleased to receive advice concerning this appointment from people with a particular interest in it. He may be contacted at the address below.

Applications stating full personal and professional details, the names of at least three professional referees and quoting reference No A5692, should be directed to:

The Secretary (Personnel)

by June 15, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER *(W983)A*

UNIVERSITY OF DURHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

Applications are invited for a New Blood Lectureship in Geophysics from 1 October 1984 or as soon as possible thereafter, to develop research programmes in the application of space geodesy to the study of earth structure and dynamics. Applicants must have previous experience in either geophysics or geodesy, and be willing to develop a broad interdisciplinary approach in both subjects.

Salary on the scale £7,190-£14,215 with supperannuation.

Applications (3 copies) naming three referees should be sent by 2 June 1984 to the Registrar, Science Laborabories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (2010)A

Sedimentary Geochemists

We currently have two opportunities for enthusiastic and flexible scientists, who should be numerate, literate and enjoy putting together different types of results to attack exciting problems. They will join a small team investigating diagenetic processes and applying this knowledge to:

★ petroleum exploration and production
★ metalliferous minerals exploration

Candidates should have either:

- a PhD
  or
- an honours degree plus the ability and qualifications for post-graduate research but preference for a career in industry

  plus

  experience of (or be happy to learn fast) the techniques of:
  - stable isotope mass spectrometry
  - geochemical analysis
  - petrography/petrology

An attractive remuneration package includes non-contributory pension scheme, subsidised restaurant, on-site sports and social facilities and relocation assistance, where appropriate.

Please write, quoting reference SR 2816, to: Mrs. Anne Hendry, The British Petroleum Company plc, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN. (2070)A

BP Research SUNBURY-ON-THAMES

POSTGRADUATE RESEARCH IN BIOLOGY

(three posts)
Salary: £5,649 — £6,363 — Pay award pending

Applications are invited from candidates with, or expecting to obtain a good honours degree in Biological Sciences, for work in one of the following areas of research:-

1. Developmental changes in the distribution and diet of *Nucella lapillus* (L.)

2. Genetics of disease susceptibility in fish.

3. Lead uptake and translocation by different crop varieties.

4. Low temperature injuries in *Chlamydomonas reinhardii* (C.W. 15+)

Research Assistants are expected to register for a CNAA higher degree. Appointments are for a period of two years with a possibility of a third year (fixed term contract).

Further details and application forms to be returned by Friday 15th June 1984, can be obtained from the Personnel Office, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA. Tel: (0752) 264639 (NB Please specify clearly for which project you are applying). (2028)A

Plymouth Polytechnic

UNIVERSITY OF BRISTOL

DIRECTOR, LONG ASHTON RESEARCH STATION

The University of Bristol invites applications for the post of Director of the Long Ashton Research Station which is the Department of Agriculture and Horticulture of the University of Bristol. The Station receives grant-in-aid from the Agricultural and Food Research Council. On appointment the Director will also assume responsibility for the Council's Weed Research Organisation near Oxford whose programme of work is being consolidated with that of the Long Ashton Research Station at Long Ashton.

The Director will be a Professor of the University of Bristol and Head of the Department of Agriculture and Horticulture.

The appointment, which is at Grade 4 of the new Open Structure of the Civil Service, carries a salary of £25,455 p.a. There is a non-contributory pension scheme.

Further particulars can be obtained from the Registrar and Secretary, Senate House, University of Bristol, Bristol BS8 1TH, to whom applications, together with the name and address of three referees, should be received not later than 14 June 1984.

The successful applicant may qualify for financial assistance with removal expenses. (2009)A

POSTDOCTORAL

position available to study the molecular mechanism of peptide action. Experience in hormone action, calcium as a second messenger, radioligand assays desirable. Salary: NIH scale. Send vita, statement of prior activities and interest, and names of three references to: Dr P Michael Conn, Professor and Chairman, Department of Pharmacology, College of Medicine, 2-512 BSB, University of Iowa, Iowa City, IA 52242. The University of Iowa is an Affirmative Action/Equal Opportunity employer. (NW523)A

MRC CELL BIOPHYSICS UNIT

Assistance is required for research on various aspects of neuronal cell biology under Dr J P Brockes. Interest in biochemistry and tissue culture is desirable, but not essential.

Qualifications: HNC, degree or equivalent.

Salary: According to experience in the range of £5491-£7747 plus £1042 London Weighting.

Apply in writing, giving the names and addresses of two professional referees to: Mr D M Drummie, MRC Cell Biophysics Unit, King's College, 26-29 Drury Lane, London WC2B 5RL.

Closing date: 4 June 1984. (2060)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF AGRICULTURAL BIOCHEMISTRY AND NUTRITION

DEMONSTRATOR

Applications are invited for the post of Demonstrator in the Department of Agricultural Biochemistry and Nutrition which will be tenable from 1st October 1984 for a period of 3 years. The person appointed will have the two-fold responsibility of running one or more laboratory courses in agricultural biochemistry and one in microbiology for students of Agricultural Science in the Faculty of Agriculture. The person appointed will also be asked to give a number of lectures on aspects of microbial biochemistry and will be expected to have a serious commitment to research.

Salary will be at an appropriate point on the Grade IB (Bar) scale: £6,310 — £8,530 per annum, according to age, qualifications and experience.

Further particulars may be obtained from the Senior Assistant Registrar (Establishments) (FP), The University, 6 Kensington Terrace, Newcastle upon Tyne NE1 7RU, with whom applications (3 copies) together with the names and addresses of three referees, should be lodged not later than 8th June 1984. Please quote ref N (2017)A

MONASH UNIVERSITY

Melbourne, Australia

DEPARTMENT OF BIOCHEMISTRY

FIXED-TERM LECTURER (3-5 YEARS)

Postdoctoral graduate for teachin medical or science students an participation in research in areas o (1) cloning and gene expression i yeast; (2) human interferon biology as well as genes and expression; (3 yeast mitochondril ATP synthetas complex; (4) monoclonal antibodie and protein chemistry. Enquiries t Professor A W Linnane.

Salary: $A24,353 — $A31,994 pa Applications including Ref n 30212A, curriculum vitae and 3 ref erees to the Registrar, Monas University, Clayton, Vic 3168 Australia, with a copy to th Secretary General, Association o Commonwealth Universitie (Appts), 36 Gordon Square, Londo WC1H 0PF, by 9/7/84, from whor Conditions of Appointment ar available.

An equal opportunity employer. (2068)A

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGICAL SCIENCES

THREE RESEARCH POSTS IN ANTARCTIC MARINE GEOLOGY AND GEOPHYSICS

Applications are invited for (A) One Research Fellow, 1A post, to investigate abyssal sedimentation in the Weddell Sea, and (B) Two Research Associates, 1B posts, for work on subduction-related processes and the early stages of Gondwanaland breakup in the Scotia and Weddell Sea regions. Post (A) is for a Sedimentologist; appointees to posts (B) will have had training in geophysics.

Posts tenable for one year in the first instance, but the project is supported by a BAS Research Contract extending to 30/9/88. Salaries according to age and experience will be:—

On the Research Fellow 1A Scale £7,190-£11,615 plus superannuation.

On the Research Associate 1B scale £6,310-£8,530 plus superannuation.

For further particulars telephone 021-472 1301 ext 2559, quoting reference G2 (A) or G2 (B).

No formal application form. Three copies of application, including curriculum vitae and naming three referees, to Assistant Registrar, (Science and Engineering), P.O. Box 363, Birmingham B15 2TT, by 30th May 1984. (2048)A

UNIVERSITY OF GLASGOW

DEPARTMENT OF DERMATOLOGY

POST DOCTORAL RESEARCH ASSISTANT

Applications are invited for the above position in a small group studying the differentiation of normal and abnormal epidermis. The successful candidate will investigate factors controlling the proliferation and differentiation of the epidermis in vivo and in vitro with particular reference to the expression of cytoskeletal proteins.

The position is supported until 31st December 1988 by a programme grant from the Medical Research Council. Initial appointment will be at a salary of £7190 pa on range 1A of the salary scales for Research and Analogous Staff with superannuation benefit.

Applications enclosing a curriculum vitae and the names and addresses of two referees should be submitted to Dr D Skerrow, University of Glasgow, Department of Dermatology, Anderson College Building, 56 Dumbarton Road, Glasgow, G11 6NU. (2063)A

Please mention

UNITED MEDICAL AND DENTAL SCHOOLS OF GUY'S AND ST THOMAS'S HOSPITALS
PAEDIATRIC RESEARCH UNIT

A Molecular Biologist is required to join a research group working on human genetics. The group is part of a multi-disciplinary academic research unit, with excellent laboratories, a scientific information service and full support facilities. The Unit includes the South East Thames Regional Genetics Centre. The molecular biology group has well established collaborative arrangements with a number of leading research centres. The applicant should have experience of recombinant DNA work, eg gene cloning, expression or structural analysis.

The appointment will be for an initial period of three years, with the possibility of an extension for a further period thereafter. Further particulars from Professor M Bobrow (01-407 7600 ext 2330).

Salary in range £7,190-£14,125 plus £1,186 London allowance plus Superannuation according to qualifications and experience.

Applications with a curriculum vitae and the names of two referees should be sent to the Secretary, United Medical and Dental Schools, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting ref PRU.

(2061)A

MEDICAL RESEARCH COUNCIL

LABORATORY OF MOLECULAR BIOLOGY
Cambridge

Applications are invited for a
CAREER NON-CLINICAL SCIENTIFIC

post with the Medical Research Council to conduct innovative research in biochemical crystallography particularly in the study of DNA protein complexes. The post is tenable in the Laboratory's Division of Structural Studies in the first instance.

Candidates should have experience in the area of the physical biochemistry of proteins and nucleic acids as well as in X-ray crystallographic structure analysis of large molecules.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information may be obtained from the Assistant Director (Administration) quoting reference SS/11.

Applications — including a full cv, publications list, the names of two professional referees and a statement of not more than 500 words describing their proposed research intentions — should be sent by (3 weeks after appearance) to:

The Assistant Director (Administration), MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH. Tel: Cambridge (0223) 248011. (2073)A

CSIRO
AUSTRALIA
ELECTRON MICROSCOPIST
(SENIOR RESEARCH SCIENTIST)
$A31,092-$A35,806
DIVISION OF FISHERIES RESEARCH
MARINE LABORATORIES
HOBART TAS

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Fisheries Research is a member of the Institute of Animal and Food Sciences.

GENERAL: The Division of Fisheries Research is a major component of the CSIRO Marine Laboratories, which is Australia's principal marine research institution. The Division currently employs about 70 scientists and 40 support staff based in laboratories in Sydney, Perth and Brisbane. The Sydney staff will be transferred in the latter half of 1984 to new laboratories being built at Hobart, Tasmania. The appointee will be located in the new laboratories which are expected to be completed about August 1984.

DUTIES: Responsible for management of the electron microscope laboratory consisting of scanning and transmission electron microscopes which will be used in research into physiology, cell biology and taxonomy of unicellular marine algae, ecology and taxonomy of protozoa and microzooplankton, reproductive physiology of fish, identification of fish eggs and larvae, and fish aging studies from growth increments (otoliths, scales, etc). The appointee must undertake a personal research program in one of the above fields with particular involvement in the micro-algal programs. Research into and development of improved techniques for preparation and examination of microalgal structure for taxonomic and biological investigations would be expected.

QUALIFICATIONS: A PhD degree or equivalent qualifications in biology with at least 6 years' post-doctoral research experience in electron microscopy. The appointee must have proven research achievement in biological electron microscopy, and extensive theoretical and practical knowledge of electron microscopes.

TENURE: Indefinite with Australian Government superannuation benefits available.

APPLICATIONS: Quoting reference No A3490, and giving full personal particulars, including details of qualifications and experience, copy of academic transcripts and the names of at least two professional referees, should be directed to:

The Acting Chief
CSIRO Division of Fisheries Research
PO Box 21
CRONULLA NSW 2230

MEMBRANE STRUCTURE, FUNCTION & PATHOLOGY

The Faculty of Medicine, University of Alberta, invites applications for the positions of Research Scholar or Senior Scholar at the Assistant Professor ($27,720-$39,820) or Associate Professor ($35,400-$51,658) levels. The successful candidate(s) must have an MD, DDS and/or PhD degrees with at least two years of appropriate postdoctoral training and must have demonstrated outstanding potential for an independent research career in an area of the structure and function of biological membranes. These positions will be long term and will be funded through an external agency, but the incumbents will enjoy all the privileges of the respective University ranks. The granting of these awards is by competition and is made on the basis of excellence.

Candidates should send their curriculum vitae, outlines of proposed research, and the names of three references to Professor E.E. McCoy, Department of Pediatrics, University of Alberta, Edmonton, Alberta, Canada T6G 2G3.

The University of Alberta is an equal opportunity employer but in accordance with Canada Employment and Immigration regulations this advertisement is directed to Canadian citizens and permanent residents.

Closing date: August 1st, 1984. (NW535)A

RESEARCH DIRECTOR

INCELL, a research oriented molecular biology and fermentation technology organization, is located in the brewing and fermentation center of Milwaukee, Wisconsin, adjacent to the University of Wisconsin—Milwaukee and Marquette University.

Applications are now being accepted for the position of Research Director of our research laboratories from individuals with recent, broad experience in molecular biology with emphasis on molecular cloning, yeast genetics, and protein isolation and purification chemistry.

The individual selected will report directly to the President to help ensure the highest quality of research at INCELL and will contribute strongly to the success of the Company.

Responsibilities will include the design and establishment of new laboratory facilities, recruitment and supervision of qualified scientists and research assistants, consultation with engineering and production colleagues associated with our technology, and overall management and budgetary responsibility for INCELL's research and development program.

Minimum requirements for this position are a Ph.D. in genetics or molecular biology, preferably with emphasis in yeast genetics, and postdoctoral experience in the techniques of RNA and DNA manipulations. Applicants must be familiar with:

- Techniques of Molecular Cloning
- Classical Methods of Yeast Genetics
- Protein Biochemistry, including methods of analysis, isolation, and purification.
- Biochemistry and Genetics of protein secretion in microorganisms.
- Familiarity with nucleic acid sequencing and oligonucleotide synthesis methodologies.

A broad overview of molecular genetics with strong emphasis on yeast genetics and an interdisciplinary approach to problem solving are key qualifications for this position along with the capability of working in a relatively unstructured, fast moving entrepreneurial environment.

Qualified applicants for this executive level position are invited to submit, in confidence, their resumes together with publications and salary history to:

President, INCELL CORPORATION
Post Office Box 11596
Shorewood, Wisconsin 53211 U.S.A.

FAST MOVING, REAL WORLD ENTREPRENEURIAL ENVIRONMENT AND OPPORTUNITY—EQUITY PARTICIPATION.

FELLOWSHIPS

UNIVERSITY OF ASTON IN BIRMINGHAM
DEPARTMENT OF PHARMACY

The Department is in the process of establishing a Pharmaceutical and Biomedical Sciences Research Institute to co-ordinate its research activities and to concentrate its resources in areas which are innovative and commercially relevant. Applications are now invited for the following posts:

RESEARCH FELLOWSHIP IN PHARMACEUTICS (Ref 607/6)

This one-year post (available immediately) would interest a recent PhD graduate in pharmaceutical or chemical sciences with interests in the physico-chemical aspects of drugs and drug-delivery. The successful candidate will be required to contribute to the undergraduate course in the physico-chemical aspects of pharmacy and the design of drug-delivery systems and to undertake research within the framework of the Drug Development Group with specific interests in drug discovery, drug development, and drug dosage-form design.

Commencing salary will be within the range £7,190 to £9,425 per annum (Research Range 1A).

Application forms and further particulars may be obtained from the Staff Officer (quoting Ref 607/6), the University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel 021-359 3611 ext 4564). Closing date 8th June 1984.

RESEARCH STUDENTSHIPS

A number of studentships (from Research Councils, Industry and other sources) are available for full-time study for a Higher Degree commencing 1 October 1984. Graduates with a First Class or a 2(i) Honours Degree in the pharmaceutical, life or physico-chemical sciences, or students expecting to graduate this summer, are invited to apply for posts within the following research groups.

Cancer Research Campaign Experimental Chemotherapy Group
Drug Development Group
Drug Mechanisms Group
Medical Microbiology Group
MRC Mechanisms of Drug Toxicity Group
Pharmacy Practice Group
Rheumatism and Arthritis Group

Applicants seeking further information on the research projects available within these Groups are invited to write in the first instance to: Dr J A Hickman, Department of Pharmacy, University of Aston in Birmingham, enclosing a curriculum vitae and identifying their particular research interests. (2052)E

E M B O
EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
SHORT TERM FELLOWSHIPS in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G. (W818)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOCHEMISTRY (DRUG METABOLISM)

Applications are invited for the post of Research Fellow to pursue a programme of research under the supervision of Dr L A Griffiths into the metabolism of O-heterocyclic drugs. Previous experience of drug metabolism research is desirable but not essential but the candidate should possess postgraduate experience in radiochemical techniques and in either h.p.l.c. or g.l.c. procedures.

Post tenable for up to two years (renewable at end of first year). Starting date between 4 June and 2 October 1984.

Salary on the Research Fellow 1A scale £7,190-£11,615 plus superannuation, according to qualifications and experience.

For further particulars phone 021-472 1301 ext 2559, quoting reference B5.

No formal application form. Three copies of application, including full Curriculum Vitae, naming three referees and indicating date of availability, to Assistant Registrar, (Science and Engineering), P O Box 363, Birmingham B15 2TT, by 25 May 1984. (2006)E

UNIVERSITY OF SASKATCHEWAN
Drug Metabolism and Drug Disposition Research Group
COLLEGE OF PHARMACY

POSTDOCTORAL FELLOWSHIP

Applications are invited for the above position to work on the synthesis and metabolic application of deuterium labelled phenothiazine antipsychotic agents.

The position is tenable immediately and is for two years. Initial salary depends upon experience. Applications, including Curriculum Vitae and the names of three referees, should be sent to: Dr E M Hawes, College of Pharmacy, University of Saskatchewan, Sasktoon, Saskatchewan, Canada S7N 0W0 (306) 343-4788. (NW526)E

MULTIPLE SCLEROSIS SOCIETY RESEARCH TRAINING FELLOWSHIP

The Multiple Sclerosis Society requires a postdoctoral Cell Biologist to work for 3 years in the first instance on the nature and function of the cellular infiltrate in the brain in models of demyelinating disease.

The post is tenable in the Department of Pathology of the Royal College of Surgeons of England. Salary on University of London scales according to age and experience.

It is hoped the appointment would be made with effect from 1st September, 1984.

Applications, which should be made by 18th June to be sent to: Professor J. L. Turk, Department of Pathology, Institute of Basic Medical Sciences, Royal College of Surgeons, Lincoln's Inn Fields, London WC2A 3PN. (2072)E

UNIVERSITY OF LONDON
Institute of Psychiatry

DEPARTMENT OF PSYCHOLOGY

RESEARCH STUDENSHIP

The Department invites applications for an MRC postgraduate research studentship. The successful applicant will register for a London PhD and can choose from a variety of projects related to current research in the Department. This ranges from studies of neurophysiological and neurochemical mechanisms in the control of behaviour in the rat to work on behaviour and personality in both normal and psychiatrically disturbed human subjects.

Candidates should hold or expect to receive first or upper second class honours degrees in psychology or a related discipline in the life or social sciences.

Applicants should write to Professor J A Gray, Department of Psychology, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, giving details of their curriculum vitae, the names of two referees and an indication of their preferred field(s) of research. Closing date: 31 May 1984. (2058)F

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF ZOOLOGY

SERC STUDENTSHIP IN CEPHALOPOD NEUROBIOLOGY

Applications are invited for the above studentship, tenable for 3 years commencing October 1984. Candidates will be expected to register for a PhD degree and must have a good honours degree in Anatomy, Zoology, Physiology or a related subject.

The research will be in the area of cephalopod neurobiology, in particular the central control and regulation of colour patterning. The main emphasis will be on applying and developing modern anatomical techniques.

Applicants should write, giving the names and addresses of two referees and full details of their academic career to date, to the project supervisor: Dr J B Messenger, Department of Zoology, University of Sheffield, Western Bank, Sheffield S10 2TN. Quote ref: R 81/G. (2021)F

UNIVERSITY OF SOUTHAMPTON

SCHOOL OF BIOCHEMICAL & PHYSIOLOGICAL SCIENCES

SERC CASE STUDENTSHIP

An SERC Case studentship is tenable from 1st October 1984 for a three year period in the Neurophysiology Department of the School in conjunction with Roussel Laboratories, Swindon.

The project will involve studies on central GABA receptors in the rat. The following methods will be used: electrophysiological studies using in vitro slice preparations and release studies using in vitro slice preparations and release studies from cortical and cerebellar slices. A knowledge of electrophysiological recording methods would be an advantage.

Applicants, who must hold or expected to obtain a I or II (1) class Honours degree in Physiology, Pharmacology, Biology or a related subject, will be expected to register for a PhD degree. Applications, including curriculum vitae and the names of two referees, to Dr R J Walker, School of Biochemical & Physiological Sciences, University of Southampton, Southampton SO9 3TU. Tel: 0703-559122 ext 8343 or 8341. (2011)F

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF MEDICAL PHYSICS AND CLINICAL ENGINEERING

RESEARCH STUDENTSHIP

An SERC studentship is available to pursue research in an area of Medical Physics leading to a PhD. The successful applicant will be expected to have obtained at least a 2.1 in physics or electronic engineering. Applications with a CV should be made to Professor M M Black at the above department; Royal Hallamshire Hospital, Sheffield S10 2JF from whom further details may be obtained. Tel: 0742 26484 ext 2712 or Dr D C Barber. 2688. Closing date 11 June 1984. Quote ref: R85/9. (2066)F

UNIVERSITY OF MANCHESTER

DEPARTMENT OF ZOOLOGY

NERC STUDENTSHIP

Applications are invited for a research studentship to investigate ecological and genetic diversity using computer modelling techniques. Candidates should have, or expect to obtain in 1984, a first or upper second class honours degree in a relevant biological subject or in mathematics or physics.

Further details can be obtained from Dr L M Cook, Department of Zoology, University of Manchester, Manchester M13 9PL, to whom letters of application including a curriculum vitae and the names of two academic referees should be sent as soon as possible. (2020)F

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

PhD STUDENTSHIP

Applications are invited for research studentship (supported b the British Heart Foundatio tenable for 3 years commencin October 1984 to study the role c vitamin B6 deficiency in the develo ment of atherosclerosis. The wor involves investigation of the mode c action of lysine oxidase, the copp and pyridoxal-dependent enzym responsible for the cross-linking c collagen and of elastin; it involv animal experimentation as well a biochemistry. A background in bi chemistry and biology is essential.

Candidates should hold, or expe to obtain a First or Upper Secon Class Honours Degree in Bi chemistry. Applicants should app in writing including their curriculu vitae and the names of two academ referees to Dr C I Leven Department of Pathology, Unive sity of Cambridge, Tennis Cou Road, Cambridge CB2 1QP. (1980)F

HERIOT-WATT UNIVERSITY

CASE STUDENTSHIP IN OFFSHORE ENGINEERIN

Applications are invited from Engi eering or Science Graduates for immediately available resear studentship. The project is concern with the effect of fouling and surfa roughness on the wave and curre loading on marine structures.

Support is for a period of thr years and the successful applica would be expected to register for higher degree. Applicants shou hold a first class or upper second cla honours degree.

For further particulars plea contact Dr I Grant, Department Offshore Engineering, Heriot-W University, Edinburgh. Telepho 031-449 5111 ext 2319. (2025)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ZOOLOGY

SERC CASE STUDENTSHI

Trematode larvae and the sn immune response.

Applications are invited fr recent graduates or those about graduate in a Biological Science fo CASE studentship leading to a Ph The project in collaboration with V R Southgate (British Muse Natural History) will investigatge t cellular basis of host-parasite int actions between the blood flu Schistosoma and the snail Bulin both in vivo and in vitro.

Applications with a curricul vitae and the names of two refer should be sent to Mr T M Prest Zoology Department, UCL, Gow Street, London WC1E 6BT fr whom further information may obtained. (2012)F

STUDENTSHIPS continued

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF BOTANY AND MICROBIOLOGY

NERC STUDENTSHIP IN MICROBIAL ECOLOGY

The NERC have awarded a studentship to the Department for studies of ColV$^+$ enterobacteria. Such organisms occur in sewage and contaminated water and are important in Public Health because ColV frequently increases bacterial pathogenicity. The aims of the project are to examine natural occurrence and location of ColV$^+$ bacteria and to isolate new ColV$^+$ strains. These will then be compared with established ColV$^+$ strains with respect to plasmid DNA content, envelope protein composition, and other plasmid specified properties. It is then proposed to examine behaviour of ColV$^+$ organisms in the environment studying (i) ColV plasmid stability, (ii) ColV plasmid transfer, (iii) competition between ColV$^+$ and ColV$^-$ organisms (especially at low iron concentrations as some ColV plasmids specify an iron chelation mechanism), (iv) survival of ColV$^+$ organisms compared to ColV$^-$ ones.

The studentship would be suitable for a candidate studying Microbiology or a related Biological subject and who has already obtained or hopes to obtain in June 1984) an honours degree with at least upper second class honours. For further details, apply to Dr R J Rowbury Department of Botany and Microbiology, University College London, Gower Street, London WC1E 6BT. (2033)F

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

BIOPHYSICS GROUP

RESEARCH COUNCIL STUDENTSHIP

Applications are invited for a Research Council Studentship for work in the Biophysics Group, for research on one of the following topics:

— Crystallography of enzymes, including molecules created by protein engineering:

— Molecular mechanisms of general anaesthesia:

— Three-dimensional structure of vertebrate muscle:

— Effects of neuroactive substances on retinal neurones:

— Kinase control of microtubule assembly:

— Design of inhibitors of angiotensin converting enzyme (CASE).

Applicants must expect or possess a good honours degree in physics, biochemistry or another relevant subject.

Please apply directly to Prof. D.M. Glow, Blackett Laboratory, Imperial College, London SW7 2BZ, with a brief C.V., naming two referees. (2036)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANTY

SERC RESEARCH STUDENTSHIPS

The following SERC research studentships are available within the Department of Botany tenable from October 1st, 1984. Two awards are available.

1. Control of secondary product formation in plant tissue cultures (Dr H A Collin).

2. Physiology and biochemistry of protoplasts isolated from Phytophthora infestans. (Dr S Isaac and Dr A M Mortimer).

3. Polymeric soil conditioners as aids to vegetation establishment on difficult soils (Dr M S Johnson).

Further details of these studentships are available from Professor A D Bradshaw, Department of Botany, University of Liverpool, PO Box 147, Liverpool L69 3BX. Applicants should have or be expecting at least a 2:1 Honours Degree in an appropriate biological subject. The Department of Botany has a very active research school with excellent facilities, concerned with pure and applied aspects of botany.

Applications should be made as soon as possible and at least by June 4th to The Registrar, University of Liverpool, PO Box 147, Liverpool L69 3BX. They should include details of academic experience and the names of two referees.

Quote Ref: RV/508/N. (2027)F

UNIVERSITY OF CAMBRIDGE

THE BIOTECHNOLOGY CENTRE

SERC STUDENTSHIPS IN BIOTECHNOLOGY

Applications are invited from graduates in appropriate disciplines for the following research studentships tenable for three years in the newly established Biotechnology Centre and involving the development of novel biological sensors for application in clinical diagnostics:

1. Fibre Optic Biosensors, SERC Quota Award, Tenable from 1st October 1984.

2. Immunologically-sensitised Field Effect Transistors (Immuno-FETs), SERC Replacement Quota Award, Tenable from July 1984.

3. Integrated Optical Biosensors, SERC CASE Studentship, Cooperating Body: Plessey Research (Caswell) Ltd, Industrial Supervisor: Dr W J Stewart, Tenable from 1st October 1984.

Applicants must hold, or expect to gain, a first or upper second class honours degree and should send a curriculum vitae together with the names and addresses of two referees and indicating which post is being applied for, to: Dr C R Lowe, The Biotechnology Centre, University of Cambridge, Downing Street, Cambridge CB2 3EF. Tel: (0223) 60153. (2050)F

NATURAL ENVIRONMENT RESEARCH COUNCIL

CASE RESEARCH STUDENTSHIPS WITH BRITISH ANTARCTIC SURVEY

Applications are invited for seven NERC CASE studentships awarded under the Antarctic Research Special Topic programme and leading to a PhD degree:

Life Sciences

Predation in a simple terrestrial community (Dr M B Usher, Department of Biology, University of York, York YO1 5DD).

Comparative physiological adaptation of selected Antarctic microbial communities to low temperature (Dr D B Nedwell, Department of Biology, University of Essex, Colchester CO4 3SQ).

Autecological study of a planktonic predatory amphipod *Parathemisto gaudichaudii* in Antarctic waters (Dr M Sheader, Department of Oceanography, University of Southampton, Southampton SO9 5NH).

Earth Sciences

Global biostratigraphy, biogeography and evolution of the early Cretaceous bivalve *Aucellina* (Dr P F Rawson, Department of Geology, University College London, Gower Street, London WC1E 6BT).

Atmospheric Sciences

Halley-St Anthony ULF-VHF conjugate studies (Dr D Orr, Department of Physics, University of York, York YO1 5DD).

Radiometric observations of ocean and atmosphere by ship and satellite borne sensors (Dr E J Williamson, Department of Atmospheric Physics, University of Oxford, Clarendon Laboratory, Parks Road, Oxford OX1 3PU).

Generation and behaviour of internal gravity waves in the atmospheric boundary layer (Dr J Brindley and Dr S D Mobbs, Department of Applied Mathematics, University of Leeds, Leeds LS2 9JT).

Studentships are tenable for three years from 1 October 1984 and applicants should hold or expect to obtain at least an upper 2nd class honours degree. Further details of projects available from the university supervisors to whom applications should be made by 29 June. (2071)F

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

SERC RESEARCH STUDENTSHIP

Applications are invited for a CASE Studentship starting date 1 October 1984. It is tenable for three years and, subject to satisfactory progress, will lead to a PhD. Applications are invited from students expecting at least an upper second class Honours degree in an appropriate subject.

The work involves strain improvement in the yeast Saccharomyces cerevisiae by manipulating genes involved in ammonium assimilation. Conventional yeast genetics as well as recombinant DNA technology will be used. The collaborating body is the Distillers Company Food Group.

Applications, with the names of two referees, should be sent to The Secretary, Department of Biochemistry and Microbiology, University of St Andrews, St Andrews, Fife. (2069)F

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

DEPARTMENT OF MEDICINE (MRC CLINICAL IMMUNOLOGY RESEARCH GROUP)

MRC STUDENTSHIP

Applications are invited for a three year MRC research studentship tenable from October 1984.

The project will be in the area of the molecular basis for the effects of persistent virus infection on the immune response, working with human cytomegalovirus.

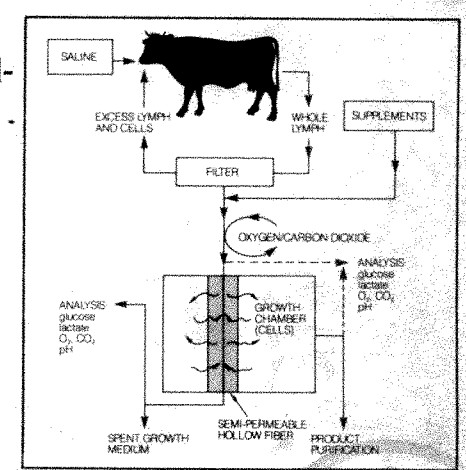
Applicants should send a full CV to the Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London, W12 OHS, quoting reference number 2/MRC.

Informal enquiries to Dr J G P Sissons on 01-743 2030 ext 345.

Closing date: 7 June 1984. (2038)F

UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY



SERC-CASE STUDENTSHIP

Applications are invited from graduates who have or expect to receive a first or upper second class degree in Biochemistry for a 3 year CASE award to work on the structure and activity of the membrane receptor for the anti-asthmatic drug, sodium cromoglycate. The project is a collaborative one between Dr J Findlay at the University of Leeds and Fisons plc, manufacturers of the drug. A cv together with the names of 2 referees should be sent as soon as possible to Dr J Findlay, Department of Biochemistry, University of Leeds, LS2 9JT. (2042)F

NATURE'S BIOREACTOR

The New Bio-Response MCT* (Mass Culturing Technique) System Delivers Monoclonal Antibodies And Other Mammalian Cell Products When You Need Them—From Grams To Kilograms.

Insufficient quantities of desired peptides are a key cause of expensive research and production delays. The MCT system is a *new* and *unique* mammalian cell culturing process designed to overcome the obstacle of insufficient quantities of peptides by delivering the quantity you need...*when you need it!* Additionally, every step in MCT production has been developed to contain costs now and in the future while maintaining exceptional purity and quality in mammalian cell proteins.

Quantity

Unlike conventional cell-culture methods, the MCT system uses "fresh," free-flowing lymph directly from a cow. Following treatment, the lymph is continuously diffused into and out of a growth chamber. This nearly *in vivo* growth environment stimulates continuous and optimal protein secretion. The result? Large quantities of desired proteins enabling you to move to the clinic or market...*faster.*

Cost

Unlike conventional cell-culture methods that require extensive labor forces and expensive growth mediums, Bio-Response's MCT is a closed, steady-state system. In essence, the MCT system starts with a low-cost lifeline—a feeding cow—and ends with a pure, quality product. MCT ...*an optimal system at low cost.*

Purity

Unlike conventional cell-culture methods, the MCT system is designed to insure purity without tedious processing. By directing the lymph across semi-permeable membranes, MCT provides both separation of media protein from desired cell products, and a continuous nutrient flow. The ability to add or withdraw from the chamber to maintain optimal cell density permits continuous harvest of a highly pure product.

Quality

Unlike conventional methods of production that attempt to create biologically active mammalian cell products, the MCT system provides a pure-mammalian product—an exact copy of the original protein and, in the case of non-antibody polypeptides, uncompromised by inappropriate glycosylation and disulfide bond formation. There is a growing consensus favoring products produced in a mammalian cell-culture system, such as the Bio-Response MCT system.

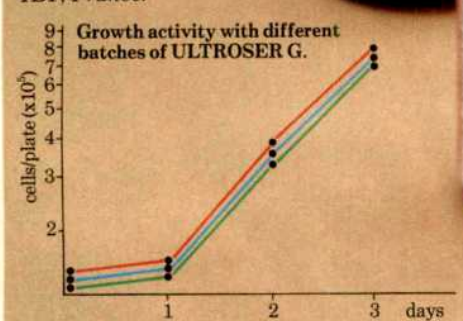
DUNLIN CHORUS LINE



CULTUR

Serum free cell growth with new ULTROSER G

batch, after batch, after batch

ULTROSER G is a serum free synthetic growth support for multi-purpose cell culture—and cuts out the pretesting needed for fetal calf and other alternatives. As a true serum substitute, its well defined composition guarantees you batch uniformity to consistently give you regular cell development and reliable control over tissue culture variability. You'll soon find out how ULTROSER G saves you time, is easy to use, simple to store and gets you results—batch after batch after batch. With 5 times less protein than FCS to simplify purification and bioassays, and the minimal amounts needed (1—3%), you'll know why so many labs like it even more. And when you discover that it comes lyophilized, ready for use and can be kept outside a freezer, you'll want to check it yourself. Get in touch with LKB, and we'll send you the latest on how to grow cells without serum—and without problems.

Trials performed with Vero cells in HAM'S F12 culture medium supplemented with 2% ULTROSER™ G. Tests carried out by Dr. E. Boschetti at Réactifs IBF, France.

FASTER THAN ALL THE REST.

IgGsorb is the IgG adsorbing agent that won't keep you waiting. It removes antibody and antibody-complexed antigen from solution in a mere 15 minutes!

Highly specific for binding the FC portion of IgG antibodies, IgGsorb is a lyophilized preparation of Protein A fixed to the cell walls of inactivated Staphylococcus aureus.

IgGsorb has more than speed too. It has long storage life. Its homogeneity can be assured. And it serves a variety of applications, in some cases replacing charcoal, double antibody, and other cumbersome methods of separation.

Plus, it's available in both liquid and dry form.

Try IgGsorb yourself and see how fast it really is. Because two hour waits you really don't need!

Let the NEN advantage in molecular biology work for you.

The NEN advantage is the superior performance you get from products at the forefront of biotechnology. In molecular biology especially we offer a variety of innovative products in response to your specific needs. Here are three examples.

Pretested research systems—
We offer three new systems: C-Tailing and Cloning, Southern Cross/Restriction Mapping, and Wheat Germ Translation. That makes 16 systems pioneered by NEN to bring convenience and reproducibility to molecular biology studies.

Autoradiography Enhancers—
We continue to lead the industry with EN^{3}HANCE™ and ENLIGHTNING™, the enhancers that drastically reduce processing time.

^{35}S-Nucleotides
Perhaps the best example of our commitment to biotechnology is our ^{35}S-nucleotides, pioneered by NEN as a superior alternative to the conventional use of ^{32}P. The technical and safety advantages of using ^{35}S are widely recognized, and we are collaborating with the research community to develop further applications.

Let the NEN advantage work for you. Ask your NEN Technical Representative to give you more information about these and our other problem-solving products for molecular biology.

Sensitive It Is. Radioactive It Isn't.

The DNA Detection System From BRL.

Until now, only a radioactive label could provide the sensitivity required for detecting small quantities of DNA. Today—with BRL's new DNA Detection System—*you can visualize even single copy genes without radioactivity.*

What the DNA Detection System is:

Sensitive. Using this enzyme-based system, together with the nonradioactive label biotin-11-dUTP, *you can detect 2 to 5 picograms of DNA.* The key to this extraordinary ability is a polymer of alkaline phosphatase, which provides far greater sensitivity than horseradish peroxidase.

Reliable. *Only BRL provides pretested reagents for making DNA test strips* on your nitrocellulose. Developed beside your filter, test strips act as an internal control, enabling you to monitor each visualization reaction.

Easy to use. All the reagents in the system—biotinylated poly alkaline phosphatase, streptavidin, dyes, biotinylated control DNA and DNA dilution buffer—are prescreened for use together. They are packaged in a convenient plastic container in which the filter can be developed. In addition, BRL's DNA detection experts have compiled a clear, step-by-step instruction manual which is included with the system. Our scientists also can assist you when you call the BRL Tech-Line™.

Flexible. You can label your DNA with biotin-11-dUTP and the nick translation reagents or labeling protocol of your choice. Of course, if you choose to purchase BRL's own Nick Translation Reagent System and our Biotin-11-dUTP, you can be assured of optimal results, because they are completely qualified for use with our companion DNA Detection System.

Rapid and inexpensive. Faster than autoradiography, the DNA Detection System actually costs less to use and requires no expensive equipment.

What the DNA Detection System Isn't:

Radioactive. Used with biotin-11-dUTP, our system has none of the safety, stability and disposal problems associated with radiolabeling for autoradiography.

Ask for our brochure and try BRL's DNA Detection System. You'll like it for what it is—and for what it isn't.

NATURE VOL. 309 24 MAY 1984

COVER

Abrupt, coordinated changes of direction in a flock of birds (like the dunlins shown here) seem to be initiated by any bird executing a maneouvre towards the flock. The "manoeuvre wave" appears to be propagated in much the same way as occurs in a human chorus line (see p. 344).

New from Amersham

Prokaryotic DNA-directed translation kit

Amersham's cell-free coupled transcription/ translation kit contains an *E.coli* extract which allows rapid and reliable synthesis of proteins encoded by appropriate exogenous DNA templates. This *in vitro* system may be used for the study of prokaryotic gene expression, identification of proteins encoded by recombinant plasmids or phage and the mapping of gene products to particular restriction fragments. Our kit:

- is available in two pack sizes: 10 reaction kit N.380Y
  25 reaction kit N.380Z
- offers a convenient alternative to *in vivo* systems
- provides fully tested components
- has low background of endogenous protein synthesis
- requires minimal quantities of DNA template (0.5-5µg/assay)
- provides solutions and simple protocols for use with L-[^{35}S] methionine (code SJ.204) or L-[4,5-^{3}H] leucine (code TRK.683)

We also supply:

M13 cloning and sequencing kits
Nick translation kits
3'-end labelling kits
λ *in vitro* packaging kits
Rabbit reticulocyte lysates
Human placental ribonuclease inhibitor

NATURE CLASSIFIED

Professional appointments — Research posts — Studentships — Fellowships — Conferences — Courses — Seminars — Symposia: Back pages

Next week in *Nature*:

- Receptor structure for human growth hormone
- Retinoblastoma and N-*myc* gene expression
- Phylogeny of *Drosophila* species from gene structure
- Colour vision in the giant clam
- Running squid sodium pump backwards
- Extragalactic IRAS objects
- Star formation in interacting infrared galaxy
- Olympus Mons
- X-ray distinction between H and D
- Surface depletion of oceanic vanadium
- Stoichiometry and inorganic structure
- Inheritance and social class

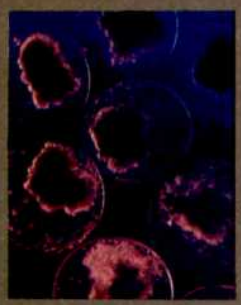
GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

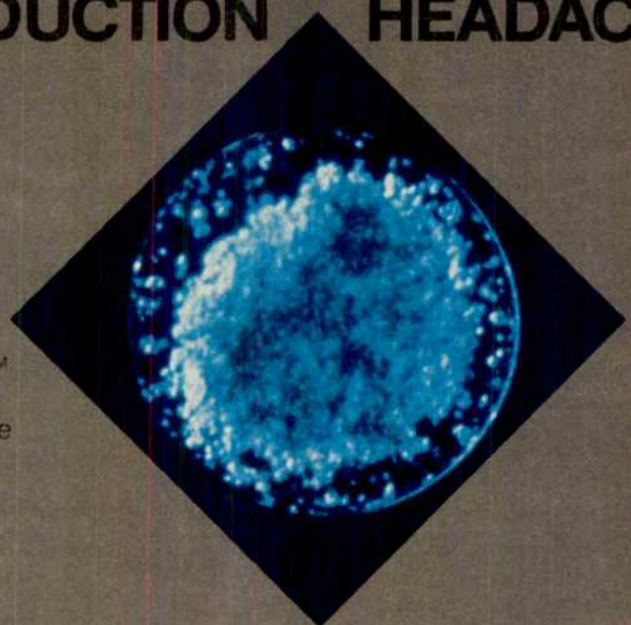


Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.



Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

Left: encapsulated human hybridoma cells growing to high density

Center: high levels of mouse antibody are produced within each microcapsule

THIS CAPSULE CURES MONOCLONAL ANTIBODY PRODUCTION HEADACHES.

With our patented ENCAPCEL™ process and your hybridoma, Damon Biotech can produce the monoclonal antibody you need when you need it. That can make the difference between getting your product to market, or watching the world pass you by.

Quantity and quality.
Grams to kilograms, we produce mouse or human monoclonals under pharmaceutical GMP standards. You enjoy the security of confidentiality with guaranteed delivery.

Purity with activity.
The antibody is produced, concentrated and dialyzed within the capsules. This avoids complex purification methods which damage the antibody and decrease its efficacy.

Product safety.
The capsules protect your product from contamination by mouse or bovine immunoglobulins. Our Regulatory Affairs Group will assist yours to expedite government approvals.

So if you need monoclonal antibodies for any product program, talk to Damon Biotech. Because the last thing you need on the way to market is another headache.

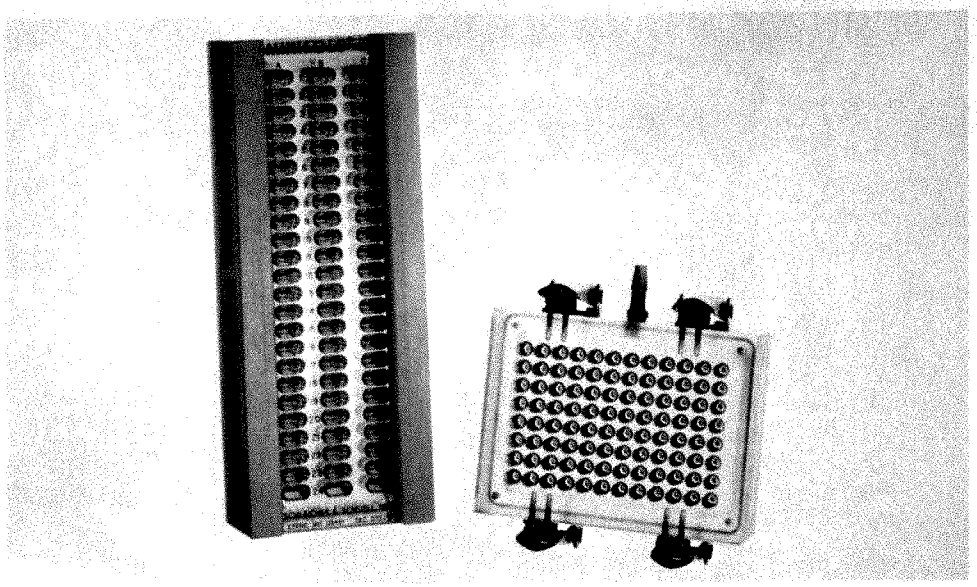
NIKON VISIONS

Rodent respiratory tissue

NIKON INVERTED MICROSCOPE TMS FOR ROUTINE TISSUE CULTURE

Perfectly simple.....simply perfect. In a busy laboratory you don't want to waste time making constant adjustments to your microscope. With the TMS you simply turn on the illumination, focus and you can get right to work examining your cells. The TMS features pre-centered phase, illumination and condenser systems.

Quickly scan roller bottles by hand. Or, use the attachable mechanical stage to accurately position 96 well plates, micro-filter plates, petri dishes, 1″×3″ slide glasses, etc., on its large low positioned stage.



Nikon's CF optics and the TMS body's innovative design give you superb contrast and clarity. A new series of high-performance, low-cost, phase contrast optics from 10× phase to a long working distance 40× phase is available in addition to a complete line of bright-field objectives. There is even a unique 4× plan phase objective for low power scanning as well as long and extra-long working distance condensers.

A high efficient 6V/20W halogen light source provides abundant illumination for low to high power observation. The TMS features include a fixed stage with focusing nosepiece, ultra-stable diecast body, human-engineered design, high eye-point eyepieces suitable for use with eyeglasses, and many other advantages. The Nikon TMS. It'll simply improve your lab.

Extend *your* vision. Write: NIPPON KOGAKU K.K., Fuji Bldg., 2-3, Marunouchi 3-chome, Chiyoda-ku, Tokyo 100, Japan.

Dot-Blotting or Slot-Blotting?

With S&S the choice is yours–Minifold I or Minifold II

Schleicher & Schuell's Minifold® units are uniquely designed for the immobilization of multiple samples of DNA or RNA *without cross lateral flow.* Both units are particularly useful for the covalent, anionic or adsorptive binding of nucleic acids in conjunction with the appropriate S&S binding medium (e.g., S&S NC™ nitrocellulose). Both are precision-tooled from rugged, polished acrylic.

The Minifold I features 96 sample wells designed in the Microtiter® format to facilitate sample handling. Each sample well is sealed with a silicone O-ring. The large filtration area per well (0.32 cm^2) makes the Minifold I ideal for the *screening* of DNA clones and optimizes the immobilization of *m*RNA in the Quick-Blot™ technique.

The Minifold II offers a convenient method for *quantitating* multiple nucleic acid samples. Each of the 72 sample wells has a very small filtration area (6.0 mm^2), resulting in a greater concentration of nucleic acids on the filter medium. The slot format of the Minifold II sample wells enhances DNA or RNA sample quantitation by densitometry.

Dot-blotting or slot-blotting: S&S is the only company that gives you a choice.

Contact S&S for further information.

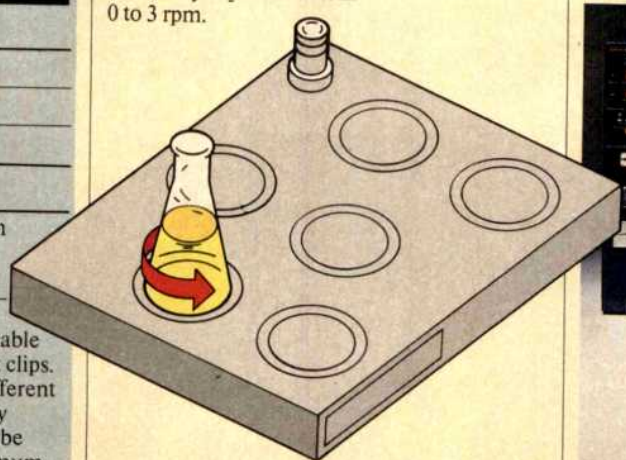
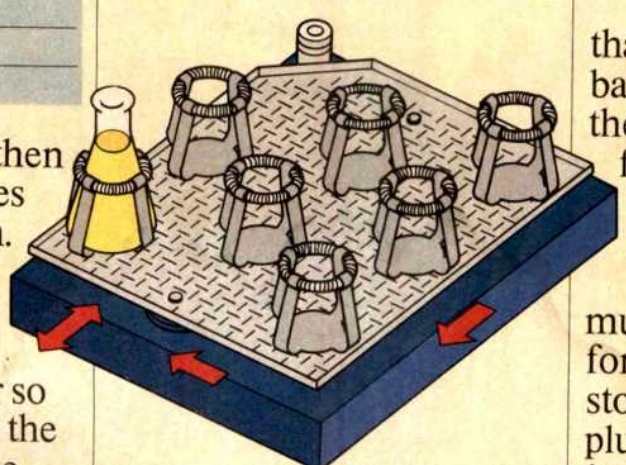
THE PLUS INCUBATOR FOR IMPROVED SHELF LIFE



By changing a shelf on any one of the new plus range of incubators you can convert it into a roller bottle, an orbital or a stirring suspension incubator, or any combination of each. It's simple! Start with one of the basic plus incubators – there are three sizes to choose from, fit a flexible drive unit and then choose a shelf or shelves to suit your application. The shelves lock into the flexible drive in seconds and simply slide into the incubator so it's very easy to change the function. And of course you can continue to use the incubator for standard incubations at the same time.



The roller bottle shelf will accept up to 3 roller culture bottles. The speed is externally adjustable from 0 to 3 rpm.

– Flexible drive powered shelves –

	Speed
Roller	Up to 3 rpm
Orbital/Linear	Up to 250 rpm
Magnetic Stirring	Up to 1000 rpm
	Capacity
Roller	3 bottles 110 mm diameter max. 370 mm length
Orbital/Linear	The platform is perforated to enable it to accept flask clips. This enables different flask sizes in any combination to be accepted. Maximum four 1 litre flasks
Magnetic Stirring	Six places
	Overall size wxd, mm
Roller	375 x 375
Orbital/Linear	360 x 334
Magnetic Stirring	370 x 340

The magnetic stirrer shelf will accept up to six flasks. The speed is externally adjustable for either gentle cell stirring or vigorous mixing.

Orbital/linear shelf. The platform accepts any size of flask clip from 25cm³ to 2 Lt. and will give either a gentle orbital action or a more vigorous side-to-side sliding action. The speed is externally adjustable from 0 to 250 rpm.

In addition to these various shelf options there are also a number of plug-in control units including temperature presets, cyclic timing or temperature recording – all of which can be bought either at the time of purchase or at a later date. The plus series incubators are quite the most versatile on the market.

Available in sizes 75, 150 and 225 litres. With a maximum temperature of 100°C the incubators are accurate to 0.1°C.

It goes without saying that Gallenkamp plus incubators are manufactured to the highest standard of specification and quality – shiny stainless steel interior, digital set and read temperature control and much more. Contact us now for the full story on the plus series incubator.

Circle No. 20 on Reader Service Card

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and ultimately for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117 U.S.A.

The conference program has been designed for two groups of people—researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: $85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E. 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

DAY 1

MONDAY, 10 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 9:30am— 6:00pm

ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00— 9:15	Chairman
9:15—10:00	Oncogenes *R. Weinberg (MIT)*
10:00—10:45	Growth factors *M. Sporn (NIH)*
11:15—12:00	HTLV *R. Gallo (NIH)*
12:00—12:30	Clinician's View *S. Broder (NIH)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	The Cancer Cell *J. Cairns (Harvard)*

DAY 2

TUESDAY, 11 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 8:30am— 6:00pm

THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9:00— 9:15	Chairman
9:15—10:00	Gene Regulation *P. Leder (Harvard)*
10:00—10:45	Hereditary cancer *R. White (Utah)*
11:15—12:00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12:00—12:30	Clinician's View *F. Gilbert (Mt. Sinai)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	NCI program

DAY 3

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am— 3:00pm
Recruitment Center: 8:30am— 3:00pm

PROSPECTS AND PROBLEMS— DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9:00— 9:15	Chairman
9:15—10:00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10:00—10:45	Immunotoxins *J. Uhr (Texas)*
11:15—12:00	Drug resistance *A. Varshavsky (MIT)*
12:00—12:30	Clinician's View *J. Gutterman (Houston)*
2:00— 4:00	Roundtables with morning speakers
4:00— 4:45	Prospects
4:45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve_____Conference Registration(s) in the names of: *(Please print or type)*

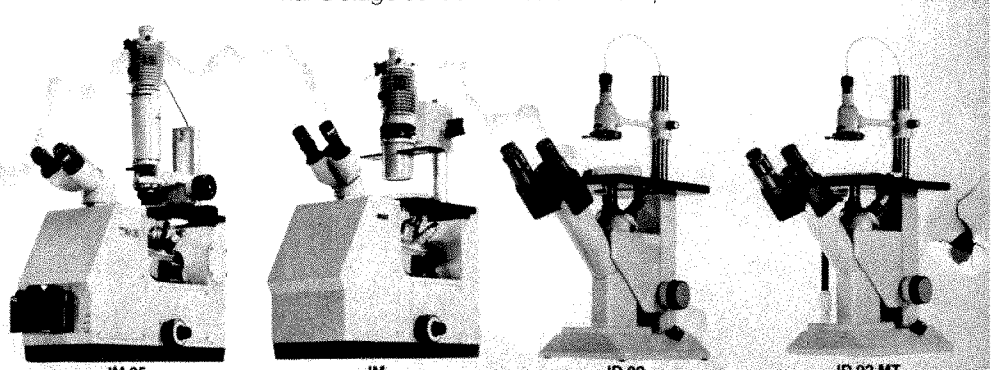
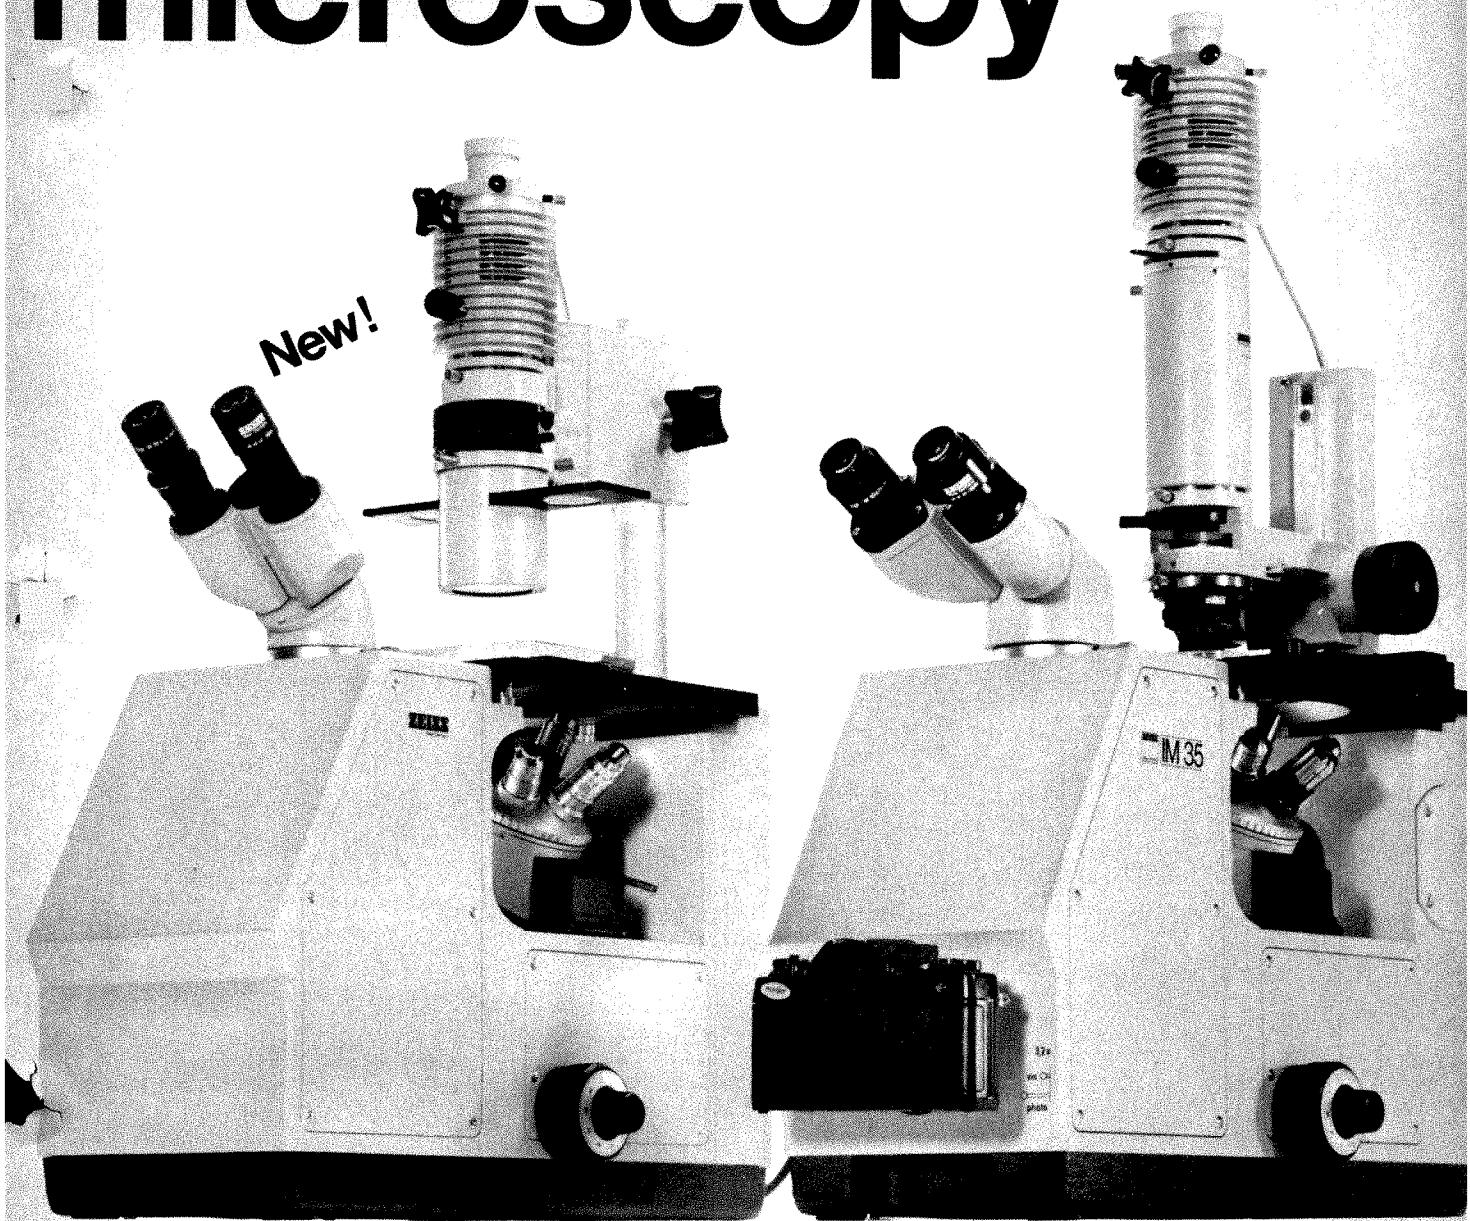
Inverted is looking up.



The use of inverted microscopes is on the rise in bio-medical research and routine applications. Today, Zeiss offers the most complete line of inverted microscopes. Each features the inimitable optics and precision engineering that have made – and keep – Zeiss pre-eminent in the field. Here are three, very affordable Zeiss inverted microscopes. Like all Zeiss microscopes, they offer the highest performance/price ratios, with more advanced features per dollar, more value, than other inverted microscopes.

For Routine Work. New ID 02 MT.



For examination of specimens in microtest or microtiter plates, in test tubes, bottles, culture dishes and flasks. Large (180 x 270mm) stage with attachable mechanical stage (85 x 125mm traveling range). Specimens are screened with deep-lying, left-hand stage control. Phase contrast optional.

Zeiss. The most complete line of Inverted Microscopes available. Contact your Zeiss dealer today for the complete story on each instrument.

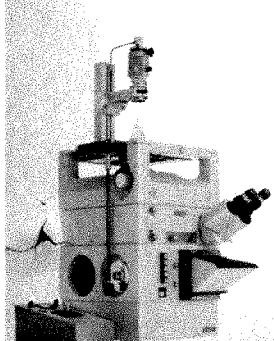
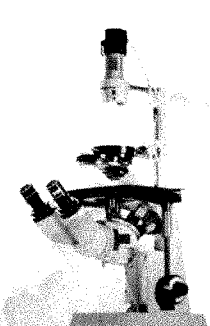
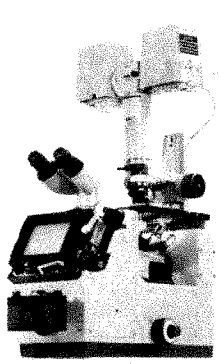
microscopy





For Advanced Routine Work and Research. New IM.



Unique, ultra-stable 3-point stage support. Ergonomic design puts all controls at fingertips for comfortable easy-see, easy-do. Swing-back illumination and condenser carrier for wide-open access to specimen and stage. Wide range of accessories for all techniques including fluorescence.

For Research. IM 35.

Accepts practically any 35mm camera back with focal plane shutter. Focusing through binocular tube. *Unique, ultra-stable, 3-point stage support.* Widest range of options for all techniques: phase contrast, DIC, darkfield, polarized light, reflection contrasts, fluorescence. The ideal instrument for micromanipulation.

REGULATION AND RESTRAINT IN CONTEMPORARY MEDICINE IN THE UK AND USA

Edited by **Dr. Hugh L'Etang,**
Editor of The Practitioner
December 1982 £32.00 224pp
ISBN 0 333 34095 7

Published jointly by the Royal Society of Medicine and Macmillan Press Ltd.

Presenting the edited proceedings of an Anglo-American conference, held in October 1981, this book examines in detail the increasing regulatory pressures placed upon medical practice and research both from inside and outside of the profession. These pressures have led to a conflicting array of self-imposed as well as legally imposed constraints, and the contributors discuss here their desirability for both the patient and the profession.

Contents

The papers are divided into five sessions:
Session I
Medicine in a regulated world
Session II
Factors which can harm the patient
Session III
Regulation and Clinical Trials
Session IV
Constraints in General and Consultant Practice
Session V
How much regulation is desirable?

Details of papers and contributors available on application.

Prejudice and academic tenure

The British Government plans to intervene directly in the ancient argument about the terms on which university teachers are appointed. It may irreparably damage the universities in the process.

BRITISH governments, even those like the present which profess that government should be unobtrusive, are chronically inclined to centralism. That is the only charitable reading of the decision (see *Nature* 17 May, p.197) that the government intends to intervene directly on the issue of academic tenure in British universities. The plan, which will no doubt be legitimized by the government's huge majority in the House of Commons, is that a group of unnamed statutory commissioners should be given the power to amend the charters which allow British universities to operate as such. The excuse, according to the Secretary of State for Education and Science, Sir Keith Joseph, is that universities have been slow, these past two years, voluntarily to extinguish academic tenure and are probably constitutionally incapable of doing so. The truth is that the present government is deeply offended by the common (but not universal) clause in British academics' contracts of employment that appointments will continue until "normal retirement age", and is impatient to see these arrangements swept away. By proposing to intervene directly, however, the government has confirmed its reputation as one that lets prejudice dictate policy.

The case for academic tenure is widely misunderstood, but derives from the doctrine that universities are self-governing communities of scholars within which people may (and will) disagree on questions as different as the allocation of car-parking space and the best route to the quantization of the gravitational field. The past six centuries have provided ample evidence that universities are most creative when individuals are able to follow lines of inquiry which their immediate colleagues may consider unproductive, and which fall outside public definitions, by governments and others, of social needs. Both in research and teaching, the indispensable social function of universities is the level-headed iconoclasm of which they are the only continuing source. Unfortunately for the government, this requires that academics should enjoy a measure of intellectual independence even from those who are titularly superiors. It would be (and when attempted is) disastrous if heads of academic departments sought to organize their bailiwicks' research as if it were an industrial research programme directed at a well-defined objective. In industry, it is proper that somebody unwilling to conform with the overall plan should be asked to find a job elsewhere. Human nature being what it is, heads of university departments are not always free from the temptation to ponder the advantages of such arrangements. The freedom to dissent even from close colleagues' opinions is what the tenure system was intended to preserve.

Security

But why should academics be insulated from the market forces to which all other people are exposed? That is what the British Government has been asking these past five years. The question is plausible enough, but begs another provoked by the way in which the British Government itself has been rigging the market in which British universities now operate. The decree more than three years ago that student numbers must be limited, and the foolish translation of this demand into student quotas for every British university by the University Grants Committee, means that British academics are unable to strive to ensure their own security by better satisfying the demand for higher education. Special public sponsorship, more recently, for the provision of higher education in fields such as information technology, while generally welcomed by hard-pressed universities, is another sign that the academic market is not a genuine interaction between self-governing communities of academics and would-be students but a process in which often arbitrary external influences play an important part. But unpredictable changes in the environment in which academics must work are not always as remote. Last week's report from the science board of the Science and Engineering Research Council (see p.297), the chief source of financial support for "small science" in British universities, says that, in future, industrial applicability will be one of the chief criteria for deciding how research grants will be awarded, thus loading the dice against academic scientists whose interests lie elsewhere. When fashion and prejudiced opinion have such an important influence on the academic market, it would not merely be unfair to expect that academics should allow their careers to be determined so arbitrarily, but would probably be impossible: potential academics would prefer to look for jobs elsewhere.

Implications

None of this implies that the tenure system as it is is sacrosanct. On the contrary, there is both a need for change and evidence that universities and those who work in them agree. Plainly, if a university as such should cease to exist, it would be unreasonable of its employees to expect that their employment should nevertheless continue. Similarly, if a university should find that student demand for some of the services it offers has collapsed, and those concerned are unable to discover other opportunities to exploit, it is only seemly that they should be invited to pursue their academic interests in some other environment. For while universities are, or should be, self-governing communities of scholars whose unique product is the outcome of successful research, their bread and butter, now as in the twelfth century, is the education of students. But the revision of the rules of tenure which the British Government is seeking will be equitable and tolerable only if it is accompanied by a restoration of some semblance of each university's freedom to decide for itself what to teach, and to whom.

The specific implications of this simple rule are plain. First, the student quotas, which are unfair to would-be students and a source of serious diseconomy, should be abolished. Since the system exists only because the government cannot think of any other way of limiting the aggregate amount of what it is required by law to pay to local authorities in respect of university fees and maintenance grants, it should quickly bend its ingenuity to helping young people now denied higher education to pay for it. Second, the market in higher education should be made to work freely in the sense that universities should be rewarded according to their effectiveness in satisfying the demands made on them. As things are, individual universities may find departments of which they are proud snatched away because some committee has decided that another arrangement would better meet the national interest. Finally, for restriction of tenure to be equitable and acceptable, universities must not merely be free to make academic decisions for themselves (with the risk of being wrong some of the time), but must do so in such a way that those whose careers are affected fully participate.

If these conditions could be met, the heavy-handed mechanism the British Government now plans to use for the enforced restriction of tenure (on new appointments only) would not be necessary. Moreover, some of the devices that have been suggested for amending the standard form of academic tenure — longer probationary periods or even periodic reviews — would be seen to be irrelevant, even counter-productive. For younger academics, and those whose chief contributions to the work of their universities is in teaching rather than research, are just as much in need of protection from tyrannical superiors as those whose research is off the beaten track. Thus the standard terms of tenure should be amended only so as to allow appointments to be terminated when a university is forced by financial considerations to contract or when, after serious and open discussion within an institution, a change of academic policy seems prudent. The need to demonstrate due process should be paramount.

Even at this late stage, the British Government should recognize that it is more likely to damage its university system beyond repair by forcing amendment of academic tenure through the parliamentary system than to gain from winning a symbolic fight with institutions already all too painfully aware of being in its pocket. Victory, of course, would allow the government to claim that it had put academics on the same basis as other professional people. Only with the passage of time would it become apparent that the supply of would-be academics had dried up. Indeed, it is even possible that signs of damage would never become so obvious that the government would be compelled to notice. Good people, notoriously mobile as things are, would seek posts in research institutes or universities elsewhere, allowing vacancies to be filled by the less able. Is that what the British Government wants? □

Banking under strain

The near-collapse of a US bank shows the need for a deal with developing countries.

THE unwelcome shadow of the Great Crash of the 1930s was abroad like the reaper last week, and it is too soon to know whether it has gone for the time being. Just as the First World War began with an assassination in the obscure Serbian city of Sarajevo, so the decade of economic upheaval of the 1930s began with the collapse of an obscure Austrian bank of which most of those affected had not previously heard. Last week's difficulties were inevitably better publicized. On the Monday, a group of New York banks announced that they had clubbed together to provide $4,500 million of credit to the Continental Illinois Bank and Trust Company, a kind of bankers' bank which has so far made its way in the world by borrowing on a short-term basis from other banks and lending on a long-term basis to other kinds of institutions, mostly commercial companies. After two disastrous years, partly attributable to a rash of light-hearted lending to oil-exploration companies (through the intermediary of an Oklahoma bank which collapsed in July 1982), the bank's bad debts had grown to more than $2,000 million, more than the value of its capital. So, inevitably, other banks became chary of lending to Continental Illinois, which is said to have been borrowing overnight money from its fellow banks to the tune of $8,000 million each day. By this yardstick, it is hardly surprising that even the $4,500 million was not enough to still the rumour mills, so that by the end of the week the US Federal Reserve, the lender of last resort, was forced to chip in a further $7,500 million to prevent Continental Illinois from going bust.

Why should that matter? Why should the Federal Reserve have gone to such trouble to save an over-ambitious bank from collapse when there are many in Congress who think it high time that the banking industry, not noticeably unprosperous, was taught a lesson? And why, if it comes to that, had not the Federal Reserve diligently exercised its supervisory powers to ensure that Continental Illinois lived less hazardously? All the answers are implied by a ringing declaration put out last weekend by the principal debtor nations of Latin America — Argentina, Brazil, Colombia and Mexico, which between them have external debts of $240,000 million. In the past two years, each of these governments has been compelled to ask its creditors for more time to pay, and for extra help (from the International Monetary Fund), and as a consequence has had to accept deflationary domestic policies. (In Argentina, for which a rescue package has still to be arranged, the rate of inflation is now 480 per cent year.) At the weekend, the four governments declared that they "cannot indefinitely accept" that "the aspirations of our peoples for development, the progress of democratic trends in the region and the economic security of our continent" should be put in hazard by high interest rates on borrowed funds and by the protectionism now apparent to suppliers of primary raw materials. This telling statement explains what has been happening in the United States because it draws attention not merely to the plight of the debtors but to the vulnerability of their creditors. The commercial banks could fall like dominoes if, in these delicate circumstances, one of them keeled over, while banking's supervisory agencies, accustomed as they have become to letting banks count as assets even their most dubious loans to developing countries in money trouble, plainly cannot be over-diligent in regulating the banks' domestic business.

The reasons why this underlying delicacy has so suddenly become apparent are also simple, and are to be found in Washington and New York. The administration's huge budget deficit, in round numbers £200,000 million this calendar year, has somehow to be matched by persuading people somewhere to buy US Government securities. If the United States were financially isolated, the result would be a high rate of domestic inflation. In the real world, much of the borrowed money comes from elsewhere, from overseas investors attracted by the high rate of interest the federal government must pay and also by the signs there have been, in the past year, of a return to rapid economic growth. The result of all this is that the dollar has been strong relative to other currencies and that the terms of trade have moved against the United States, which is likely this year to spend $80,000 million more on imports than it will earn from exports (which will again be financed by borrowing from abroad). But an election year is hardly the time to expect the federal government to change its tack.

Where all this will lead is anybody's guess. To the extent that Continental Illinois will now have been able to replace some of its short-term debt, interest rates should fall temporarily but at the expense of the inflation rate (which will be slower to respond). Sooner or later, there will have to be a settlement with Continental Illinois, in the course of which the bank's shareholders will be the chief losers (the consequences of which will be modestly deflationary). Whether these mildly beneficial effects will last until the presidential election in November is uncertain; most probably, they will not, for the commercial banking system will long before then be grappling with the next crisis among the debtor nations. To judge from the weekend declaration, that negotiation will be more tricky than the successful attempts to reschedule the payments of debt which there have been in the past two years, when the commercial banks have safeguarded their assets (loans) by lending debtors part of the money required to pay past interest, relying on tough economic recipes dictated by the International Monetary Fund to help ensure that the amounts outstanding will also in due course be paid.

What the Latin-American debtors now say is that they cannot continue to toe the bankers' line. Instead, they plead that there should be a conference later in the year to consider ways in which they could earn their way out of trouble by being helped to sell raw materials to their industrialized creditors. The catch is that the volume of debt is far too great to make that a practical proposition, even though, on this occasion, the commercial banks will be eager for any help that such a device could bring. The stratagem of replacing all the debtor nations' obligations by long-term loans from some international organization, which would safeguard the commercial banking system, is in many ways objectionable, but may be the only course open to the industrialized West when it holds its summit meeting in London next month. □

Direct broadcasting satellites

Japanese fury over US component failure

Tokyo

THE failure of US-assembled components in Japan's Yuri 2A satellite — the world's first direct television broadcasting satellite (DBS) — has provoked a furious reaction from the Japanese Government. In language normally reserved for serious clashes over trade imbalances, the Minister of Posts and Telecommunications, Keiwa Okuda, told visiting US Vice-President George Bush last week that the government took a "serious view" of the breakdown of two out of three of the satellite's transponders.

Yuri 2A was launched in January to improve reception of the state broadcasting system (NHK)'s two television channels for around one million people living in mountainous regions, remote islands and high-rise "urban canyons". But with only one transponder functioning, NHK has abandoned plans to broadcast its second educational channel. A spokesman for Toshiba, the satellite's main contractor, said the malfunctioning units were manufactured by Thomson CSF of France and assembled by General Electric in the United States.

The angry reaction to the failure does not, however, reflect disappointment at the loss of educational broadcasts but the critical role Yuri plays in a whole set of conflicting aspirations for the Japanese telecommunications, satellite and electronics industries.

All the technologically-advanced nations are now making plans to introduce direct satellite broadcasting. By being first off the mark, Japanese manufacturers had hoped to establish themselves as the number one suppliers of receiving equipment. The parabolic antennas and decoders needed to receive NHK broadcasts are already on sale in every corner electronics store in Japan, and Toshiba and a Nippon Electric Company (NEC) affiliate have been named as suppliers by Satellite Television of the United States, which hopes to have its own satellites ready by the end of 1985. The failure of Yuri is bound to affect sales in the home market, which would have built up experience for the international market.

The same companies are also eyeing the much bigger technological opportunities to be offered by DBS in the future. Japanese companies believe that DBS will be used in the 1990s to begin high-definition television broadcasts. Already Japan is the world leader in this technology. As long ago as 1968, NHK research laboratories had produced a system with 1,125 lines — almost twice the number currently in use in the United States and Japan (525) and in Europe (625) — which gives a picture no different in quality from commercial 35-mm movie projection. The trouble is that this NHK technological advance can only be capitalized upon if the 1,125-line system is adopted as an international standard. Strong competition is now coming from a 925-line system developed in the US Advanced Television Project at Massachusetts Institute of Technology. Technically the US system looks superior because it requires less transmission capacity.

Both Sony and Matsushita Electric will have 1,125-line systems ready for the marketplace by 1986. And by getting working systems out as soon as possible — beginning with mini "video theatres" — they hope to push international acceptance of the 1,125 standard. Any slowing in the pace of satellite development is seen as a long-term threat to the technological lead they will have when DBS becomes available for high-definition television.

More immediately worried by Yuri's failure are big businesses which want to buy communications satellites to transmit their own business data. Only a year ago, Keidanren (the Federation of Economic Organizations), backed by the satellite building lobby, was insisting that all Japan's satellites be domestically developed and the goverment was refusing to permit businesses to import satellites. It was a combination of pressure from the United States, which saw yet another import barrier, and from businesses which want to use satellites and know that it will be far cheaper to buy them ready-made from the United States, which forced the government to change its mind at the end of last year and to allow at least communications satellites — if not other categories — to be imported.

The failure of Yuri now has the domestic satellite makers screaming for foreign imports to be stopped again — on the grounds that they are too unreliable. But the potential users have already formed a 30-company group to purchase a communications satellite from the United States. Their counter-argument is for a domestic satellite which will still have to contain a high percentage of foreign parts.

Criticism is also coming NHK's way for having the satellite built with exceptionally powerful transponders. This move had been strongly opposed by engineers favouring the use of already-tested designs but had gone ahead to make it possible for the transmissions to be received on smaller antennas. Now NHK is wondering what to do with Yuri 2B, an identical satellite scheduled for launch in the summer of next year. Should it be rebuilt or launched as it is?

For the time being anyway, NHK is cutting its losses by licensing the satellite as an "experimental" rather than "broadcasting" service with the Ministry of Posts and Telecommunications. No charges will be made for those who have bought antennas and are receiving Yuri's fitful broadcasts.

Copyright for software in Australia

Canberra

THE Australian Government has announced its immediate intention to extend to computer software the copyright protection usually given to literary works. This should end the present uncertainty about the legal status of software following the decision of Mr Justice Beaumont in the APPLE COMPUTER *versus* COMPUTER EDGE case late last year that certain types of computer software were not protected by copyright under the 1968 act. The case is still under appeal before the full federal court.

A joint statement issued on 15 May by the Attorney-General and by the Ministers for Industry and Commerce and for Science and Technology, says that the intended inclusion of software in the existing copyright category of "literary works" rather than under the less restrictive patent law is intended to stimulate research and development in the local software industry.

Unless a federal full court decision supervenes, it is intended that passage of the proposed legislation should be secured in June, and should be understood as a short-term measure. It will not pre-empt consideration of fundamental issues remaining to be resolved, both at the domestic and international levels, on long-term policies for the protection of software and works stored in or created with the aid of computers.

Genetic engineering

Rifkin wins interim injunction

Washington

AN experiment that would have been the first to release recombinant organisms to the environment was blocked last week by a federal judge (see p. 301). Granting a motion filed by anti-genetic engineering activist Jeremy Rifkin, Judge John Sirica ordered the University of California not to proceed with the experiment of Drs Steven Lindow and Nikolas Panopoulos until a full hearing can be held on Rifkin's lawsuit, which challenges last year's approval of the experiment by the Recombinant DNA Advisory Committee (RAC) of the National Institutes of Health (NIH). RAC was also enjoined from considering other proposals for deliberate release of recombinant organisms while the case is pending.

The Lindow experiment was to have tested the ability of altered strains of the bacterium *Pseudomonas syringae* to protect potato plants in the field against frost damage. The altered bacteria have a deletion for the gene responsible for an ice-nucleating protein excreted by the wild bacteria on the leaves of plants.

Attorneys for the University of California said they would immediately appeal. According to Dr Lindow, if the experiments cannot begin this week or next, they will be delayed until the autumn, when temperatures at the test site in northern California once again drop below freezing. The experiments, originally planned for last autumn, were postponed when Rifkin threatened at that time to seek an injunction (see *Nature* **306**, 349; 1983).

Sirica's unusually detailed ruling on the preliminary injunction strongly suggests that he will also find in Rifkin's favour when the hearing is held. Rifkin is claiming that NIH should have filed environmental impact statements before approving the Lindow experiment. The ruling does not affect private industry, but only experiments carried out with NIH funds. Advanced Genetic Systems has submitted a proposal to RAC for an experiment virtually identical with Lindow's which is likely to be approved at the next meeting of the committee.

Although the ruling is a victory for Rifkin, Sirica made clear that he was making no judgement on the scientific issues that Rifkin had tried to raise. Sirica's judgement says that he was deciding only "narrow legal questions" and, during last week's hearing, he repeatedly rebuffed attempts by Rifkin's attorney to present testimony from scientific experts.

If Sirica finds for Rifkin in the full hearing, the immediate effect will merely be to require an environmental impact statement, but Dr William Gartland, executive director of RAC, said that process would take a year or more. The consequences might be that investigators would meanwhile carry out their experiments in other countries — or industry-sponsored research would proliferate.

Lindow's experiment, first considered in October 1982, was unanimously approved at the April 1983 meeting of RAC. During its brief deliberation, the committee noted that Lindow had already performed identical experiments involving chemically-mutated bacteria without ill effect and that the experimental proposal had been modified to meet earlier concern.

On both occasions, the proposals were published in the *Federal Register* for public comment; none was received on either occasion. According to Sirica's ruling, NIH made two mistakes in handling the matter. First, they failed to prepare a "programmatic" environmental impact statement in 1978, when the guidelines were modified to permit deliberate-release experiments at the NIH director's discretion.

Second, they failed to carry out even an "environmental assessment" of the Lindow experiment. Sirica rejected the US Government's argument that RAC's deliberations constitute an environmental assessment, saying he was "confident that the plaintiffs have identified several areas of plausible environmental concern which are not rebutted on the record before this Court".

Andrei Sakharov

Birthday gloom and celebrations

New York

LAST Monday, 21 May, the 63rd birthday of Dr Andrei Sakharov, the dissident Soviet physicist now in internal exile in Gor'kii, was marked by various and diverse events. In the Soviet Union, Dr Sakharov himself, who with his wife has been on an open-ended fast since 2 May, was removed, over the weekend, to a nursing home, where he is reportedly being forcibly fed. At the same time, the Soviet media stepped up their attacks on Sakharov's wife, Elena Bonner, on whose behalf he has undertaken the fast, accusing her, in effect, of exploiting her husband. In the United States, however, the day was marked by a concert in New York's Carnegie Hall, and the conferring *in absentia* of two honorary degrees, by the Universities of Long Island and of Pennsylvania.

The concert and the degree ceremonies were, of course, planned long ago. Nor is this the first time that Sakharov has received an honorary degree. Moreover, some of the formal speeches placed relatively little emphasis on the current plight of Sakharov and his wife, but delivered very much the same message on the scientist's responsibility to society as they would otherwise have done.

Sakharov's physicist colleagues, however have responded to the latest events. Last week, 36 members of the US National Academy of Sciences (of which Sakharov is an honorary foreign member), including 13 Nobel laureates and the presidents of the American Academy of Arts and Sciences and the American Physical Society, sent a cable to the Soviet leader, Konstantin Chernenko, stressing their "deep concern" and saying that the death of either Sakharov or his wife would create "very severe and long-lasting damage to efforts to maintain and to improve collaboration and cooperation with our Soviet colleagues". A "humanitarian act to save the Sakharovs", rather than "the creation of martyrs" is, they urge, "surely the common concern of all".

The Soviet view, however, is that they are *not* creating martyrs, but forestalling an anti-Soviet plot. Adequate treatment for Mrs Bonner's heart condition is, they say, available in the Soviet Union. Her demand to go abroad (the repeated refusals of which triggered the fast) is, according to TASS, the official Soviet news agency, only so that she might become "one of the leaders of the anti-Soviet scum on the payroll of the Western special services".

As early as 4 May, TASS described a scenario in which "with the participation of American diplomats. . . Sakharov would declare another 'hunger strike' while Bonner would receive 'asylum' in the US Embassy in Moscow" for the purpose of meeting foreign correspondents and "for the transmission abroad of slanderous fabrications about the Soviet Union. This "operation", TASS claimed, was "frustrated" by the "timely measures taken by the Soviet law-enforcement agencies".

The US Embassy in Moscow and the State Department in Washington immediately denied any US involvement in such a plan. Last Saturday, however, the *New York Times* quoted unnamed State Department officials as admitting that Sakharov had appealed to the embassy to shelter his wife during the fast but that, since the embassy had not received Sakharov's letter until after Mrs Bonner had left Moscow for Gor'kii, they had not discussed either the appeal or the fast with her. The same issue of the *New York Times* also carried a story, originating from Jean Daniel, editor of the Paris weekly *Le Nouvel Observateur*, claiming that there had been "indirect" approaches from Soviet diplomats suggesting that the Sakharovs would be allowed to leave the Soviet Union if President François Mitterrand of France called for a halt to the deployment of medium-range nuclear missiles in Western Europe by the North Atlantic Treaty Organization (NATO).

Vera Rich

UK research support

Industrial promise to be blessed

THE science board of Britain's Science and Engineering Research Council (SERC) has given notice to the research community of how it wants to develop its new "active" research funding policy. "Clear industrial potential" seems to be one guiding principle. The board has drawn up a novel classification of the research it finances and has initiated reviews which, it claims, are already suggesting neglected areas.

In a policy statement published last week, *A strategy for support of core science*, the board says that reviews being carried out by its separate committees stress the importance of access to advanced instrumentation and adequate provision of personnel. In chemistry, where the most progress has so far been made, the synthesis of new materials and the study of catalytic reactions at surfaces will receive a higher priority, while low-dimensional structures, protein engineering and chemical sensors are among interdisciplinary areas identified as "research themes" deserving more support. For biology, image-processing and neuroscience are short-listed priority areas.

The science board is the largest of the four main arms of SERC and finances research worth £70 million a year. But it has been under increasing financial pressure in recent years, and this has emphasized the need to take a more directive role in selecting research areas, according to its chairman, Professor John Cadogan. Research grants to university workers, for example, fell from £24 million in 1977–78 to £19.5 million in 1982–83 (1982 prices), and 30 per cent of grant applications deemed worthy of "alpha" status are now going unsupported. The remainder of the science board's budget divides roughly equally between supporting research students and maintaining and developing central and regional facilities such as the synchrotron radiation source at Daresbury, Cheshire, and the central laser facility at the Rutherford-Appleton laboratory in Oxfordshire, as well as university installations. Cadogan is quite candid about his aim of securing a bigger slice of SERC's budget for the science board.

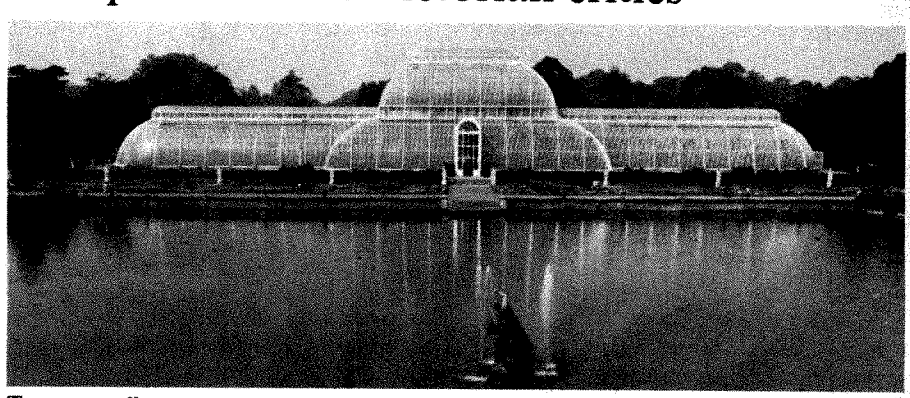
Many feel that astronomy and nuclear physics, each of which has its own board within the research council, are overrepresented on SERC's governing body. A recent proposal to merge them was dropped despite the personal backing of SERC's chairman, Professor John Kingman. Cadogan, an industrial chemist, is diplomatically noncommittal, suggesting that maybe the time was not right. But the failure of the idea will not have made his crusade for core science any easier.

The new strategy is an attempt to get away from the system used to assess grant applications before 1982, when each was assessed strictly on its own merits. Now the board will decide what the priority subjects should be, although it stresses that there will be continuing reviews.

It seems possible that in future more research with clear economic potential will be supported. Here the new strategy document appears somewhat uncertain. "It is not the science board's job or intent to support research specifically for industry", it declares boldly, adding, however, immediately afterwards that it "believes it must support core science in such a way that British industry prospers". Nevertheless, the board insists, it remains a fundamental tenet of its philosophy that funds must be made available for "outstanding scientists" on any problem of "excellence, timeliness and promise". The idea of a special fund for such "blue sky" research was dropped, however.

The science board's most urgent priority now is to increase again the amount that it can spend on research grants, and a strong case along these lines is contained in SERC's submission to the Advisory Board for the Research Councils on scientific opportunities for 1985. Something of the new subject strategy exercise has also found its way into this document, although the full impact will not be felt until next year's survey of opportunities for 1986. In the meantime, the details of "research themes" in most subjects are still being worked out, and the science board hopes its new document will be circulated widely and attract comment. **Tim Beardsley**

Education in Canada



Washington

THE Science Council of Canada has joined the international stampede to declare the need for "sweeping" changes in the ways its schools teach science. In a new report for the Ministry of Science and Technology, the council says that most teachers are underqualified and that science textbooks and curricula present a picture of science so oversimplified that it is no longer authentic. Unlike a similar report published last year by the United States' National Science Board, however, the Canadian study claims that dramatic improvements can be made without large expenditure and by working through existing institutions.

The report's principal recommendation is that all elementary school children should receive science education as proposed in the official policy statements of provincial ministries of education. The Science Council concluded that these policies are seldom observed and that most children are given only "token" exposure. The council is impatient with the argument of many elementary schools that science is "integrated" in other class activities, believing "integration" to be so vague as to be of little value. It says science should be taught as a specific subject for at least 10 per cent of the time.

Another major issue raised in the Canadian report is the quality of science textbooks. The council does not quarrel with their accuracy, but says they fail to convey a realistic sense of the way in which research is conducted and of the link between science and technology. Peter David

Kew palms off its Victorian critics

THE normally serene surroundings of the Royal Botanic Gardens at Kew, on the outskirts of London, have been rudely disturbed in recent months.

Bitter arguments have raged over plans largely to reconstruct the outstanding 19th-century palm house (above), designed by Richard Turner and Decimus Burton and the inspiration for tropical plant houses the world over.

The building is in poor structural condition and now has to be painted every two years, while 600 panes of specially curved glass have to be replaced annually. But renovation plans put forward by the Property Services Agency of the Department of the Environment have aroused the ire of the Victorian Society, among others. The existing wrought-iron glazing bars will have to be replaced with stainless steel, because wrought iron is not now available in sufficient quantity.

Some sort of compromise on the scheme has now been reached. But the Garden History Society is still unhappy with plans to increase the extent of the plant beds and so cover the iron grating floor, although the plants grow best in beds. Tim Beardsley

Silicon manufacture

Monsanto sets up in Britain

THE United States chemicals group Monsanto last week announced plans for a £65 million investment in a new British silicon wafer research and production operation. The intention is further to improve crystal purity, which will involve developing new instrumentation, and eventually to manufacture wafers of up to 8 inch (200 mm) diameter. Monsanto expects to collaborate extensively with British university departments. World supplies of silicon wafers manufactured to the required purity and high degree of flatness are at present restricted to relatively few manufacturers. Demand is expected to increase rapidly, however. Monsanto is a leading supplier to the semiconductor industry in the United States but lags in Europe. The new Monsanto facility will be at Milton Keynes, a new development town in central England. The company explains that it was looking for a green-field site, which Milton Keynes possesses in abundance, and that Britain was chosen from a short-list of eight European countries. The British Government has helped with grant assistance, although the amount is not being made public.

In declaring its intention to move towards 200-mm wafers, Monsanto seems to be making the point that it wants to keep two steps ahead of the competition: elsewhere, 150 mm is proving difficult. Monsanto boasts leadership in producing 125-mm wafers in a peak-to-valley flatness of less than 2 micrometres. But as modern wafer-stepping semiconductor manufacturing techniques become more widespread, edge-to-edge flatness will cease to be a major constraint. Local slope and crystal purity may become the limiting factors to cramming semiconductor devices onto wafers.

Two trends are combining to make purity a problem. First, chips are becoming larger, so that there is a decreased chance that each chip will be flawless. Second, channel widths are now moving down to the order of micrometres so even very small local deformities in crystal structure can disrupt a device. Implanted ions tend to spread from their original deposition sites during the manufacturing process, for which allowance has to be made in the design. The extent of the spread is determined by the structure and purity of the original lightly-doped crystal, and this is where the thrust of the research effort is likely to be. Initially, Monsanto will import wafers from the United States for cleaning and polishing in Britain, but will later embark on crystal manufacture, hoping eventually to supply 50 per cent of the British silicon market. **Tim Beardsley**

Research councils defend manning

SIR Hermann Bondi, chairman of the Natural Environment Research Council (NERC), appeared before the Public Accounts Committee of the House of Commons on 14 May to give a doughty defence of his council's manpower planning. The National Audit Office recently criticized research councils and the Department of Education and Science for apparent laxity in their planning controls (see *Nature* 309, 104; 1984), and suggested that there had been an unexplained upward drift of salary grades at councils including NERC. But, according to Sir Hermann, the increase in the number of senior posts was a planned development and a completely appropriate outcome of the changing role of NERC.

Sir Hermann said that over the past 10–15 years the need for lower-grade NERC staff on foreign aid programmes had decreased, as local inhabitants had been trained to take over their jobs. The simple result was that the staff NERC retained were now in higher grades. He also asserted that NERC institutes such as the Institute for Marine Environmental Research were deliberately established with young scientists who would climb up the ladder of promotion.

Sir Hermann also pointed out that scientific equipment had become more complicated, so that many measurements that were formerly made manually are now made by computer. This also led to a smaller requirement for lower-grade support staff.

He went on in stirring style to turn the tables on MPs who had been led to doubt whether the research councils were discharging their manpower planning duties effectively. The main charge of the National Audit Office was that the research councils had not been keeping their staff grades in line with those in the civil service. The Public Accounts Committee was particularly worried about "fluid grading" of science research posts. Sir Hermann's ingenious reply was that manpower planning in NERC is better than that in the civil service. The in-house system of visiting groups, promotion boards and annual reviews was all that could be desired.

The committee's next witness, Dr Ralph Riley, secretary of the Agricultural and Food Research Council, said that the controls on manpower in his council were similar to those at NERC, so much the same arguments applied.

The committee appeared well pleased with these answers. But research councils have not escaped completely unscathed. Mr David Hancock, permanent secretary at the Department of Education and Science, used the occasion to announce a "thorough review" of fluid grading. Tim Beardsley

US high-technology investment

Partnerships lose shine

Washington

THE downturn in high-technology stock prices is hampering efforts by biotechnology companies to raise research and development funds through other routes as well. Last week, Biogen revealed that it has raised only $25 million of the $40 million it had been counting on for a research and development partnership to finance the company's commercial development of gamma-interferon and interleukin-2. In recent weeks, other biotechnology research and development partnerships have met with a similar reception from investors. Hybritech was able to raise only half of the $80 million it was aiming for; and Centecor, which had hoped to raise $10–$15 million, now says it will be happy with $5 million.

Research and development partnerships are attractive to companies because they can provide stable support for long-term research and because they are a source of capital which does not dilute the equity holding of existing shareholders. Private investors obtain immediate tax benefits and later receive a share of the royalties from any inventions arising from the research. The partnerships are especially useful to emerging industries such as biotechnology which do not yet have products on the market and thus do not have a reliable source of revenue. They also give the companies far greater freedom than they would have if they entered into agreements with a single corporate research sponsor.

In the Biogen offering, the company ended up putting $35 million of its own money into the research and development partnership, considerably more than the $20 million it had planned.

The lack of enthusiasm for the partnerships reflects several developments. Biotechnology stocks have not been doing well on the market lately. What is more, several limited research and development partnerships in the computer field have recently received unfavourable attention for their failure to produce commercial products, which has tended to give all high-technology ventures a bad name. The most prominent case was that of Storage Technology, which raised close to $100 million for a research and development partnership that was to produce a mainframe computer to compete with that of IBM.

Nelson Schneider of E.F. Hutton says that another factor behind the poor reception for research and development partnerships in biotechnology is that there is now much more competition for the investors' dollars. "There are literally dozens out there in the market in the $2–10 million range in biotechnology", he says. **Stephen Budiansky**

Australasian science

Going all the way with B.J.

Canberra

THE 54th Congress of ANZAAS, the Australian and New Zealand Association for the Advancement of Science, was held amid the fading autumn colours and falling leaves of the spaced-out campus of the Australian National University. For five days from 14 May, the congress generated wide coverage of popular items in the press and on radio. Yet the congress lacked the focus promised by the stated theme of "Horizons of Science". The congress was woolly at the edges and soft at the centre.

For decades, the peripatetic congress has struggled to resolve the inherent tension of providing both parallel specialist meetings and cross-disciplinary exchange. Other conflicts surfaced again, notably the confusion about objectives. Is ANZAAS primarily seeking to communicate the latest results, ideas and challenges in science to the wider public and, incidentally, to persuade politicians of the importance and relevance of science? Or is the event principally for academic discourse? At Canberra, neither promise was fulfilled.

Among the 1,600 delegates — a big drop from earlier meetings but still the largest meeting on the Australian academic calendar — were relatively few who had come to listen and to discuss. With more than 1,000 papers being delivered, the speakers outnumbered others. People from outside the academic or research spheres were notably absent. To reach the public at large, or even groups such as schoolteachers and students, ANZAAS relies entirely on journalists.

The trend away from science and technology towards the social sciences and humanities continued. Of the 33 specialized sections, only 15 were devoted to the sciences and technologies, and some were pitifully weak.

The "Horizons of Science" theme, only dimly reflected in the congress programme, was almost totally ignored by individual speakers. Thus a showcase for the current state of Australian science was left empty. But some of the congress-wide symposia produced fruitful discourse, tackling issues of current concern in Australia which as exotic diseases, science and political decisions, technology strategy and nuclear arms. The last, with Petra Kelly and retired General Gert Bastian, parliamentary members of the West German Green Party as visiting attractions, was the best attended, reflecting the growth of the peace movement in Australia.

This symposium even produced a collective statement by a working group on the effects of the British nuclear tests carried out in the Australian desert between 1952 and 1963. Allegations of a cover-up by the British of aspects of these tests have become the centrepiece of a major diplomatic row between the Australian and British Governments and the rallying point for anti-nuclear protests in Australia. The ANZAAS group called on the Australian Government to conduct a comprehensive interdisciplinary study of the effects of the British tests, saying that a committee formed by the Department of Resources and Energy is inadequate.

ANZAAS was not entirely at odds with the federal government, however. Professor Sir Gustav ("Gus") Nossal, this year's president, gave one of the most glowing tributes to a politician by a scientist in recent times. An immunologist and director of the Walter and Eliza Hall Institute for Medical Research in Melbourne, he solidly backed the discussion draft released in April by Mr Barry Jones, Minister for Science and Technology (see *Nature* 3 May, p.6).

The draft, he said, was "the most significant and courageous document to come out of Canberra on any topic in the past decade". The ANZAAS president went on to urge that the minimum realistic incentive for industry to increase its commitment to research and development would be a tax credit of 150 per cent.

Sir Gustav saw "the most significant, marvellous and stunning element" in the technology strategy draft as being the proposals for achieving 50 per cent completion of secondary school (from 36 per cent now) and 20 per cent of tertiary education (a doubling of the present figure) by 1995. While critical of the emphasis on the quantity of education and of the view that the draft was "singularly silent on quality", Nossal hs put his reputation on the line as an influential backer of Jones.

Not everybody in Canberra approved. Professor Gordon Reid, until recently at the University of Western Australia and soon to be governor of the state, said Sir Gustav's statement was not based on scientific inquiry and accused him of "exercising hyperbole in his role as president".

Professor Reid said Sir Gustav's statement was an example of the ambivalence of Australian science. In one breath, he said, scientists plead for freedom from government direction, and in the next for more financial support.

Nossal is unrepentant. "A tremendous challenge is faced by the Australian scientific community to explain ourselves better. . . and to promote a technological culture. We scientists should inform the public about what we are doing, about what practical results can realistically be expected, and about what longer-term dreams can legitimately be espoused."

Later, he complained of "the besetting sins of Australian scientific academics of treating PhD students as clones of themselves and of shunning applied orientations for their research". He asked university administrators to treat their relations with the media and the public "seriously and as a sacred duty".

By defining its role in terms of facilitating communications among scientists and between scientists and the public, ANZAAS might be expected to take a lead in solving the problems posed by its current president. In reality, ANZAAS has little to offer between congresses as its central organization is weak and strapped for cash (it receives no government support and has fewer than 3,000 subscribing members).

However, bold plans for change were announced by the organiizers of the next congress, to be held in Melbourne in August 1985. They will virtually abandon the specialized sections and, through a broad grouping of interests under seven headings, will redirect their offerings to young people and the general public (both of which groups were noticeably absent from the Canberra congress) while attracting scientists to interdisciplinary sessions which will explore the current "state of the art" and identify promising new directions.

Peter Pockley

Nature banned (1937)

As part of the continuing availability of German documents of the 1930s, it has come to light that the National Socialist government issued a decree, circulated to all university and research libraries, requiring that copies of *Nature* should not be made generally available. Moreover, the decree required that its own existence should be secret.

The text of the decree, dated 12 November 1937, is as follows:

> **Articles are often published in the London weekly scientific journal *Nature* containing outrageous and vile attacks on German science and the national socialist state. The journal must therefore be excluded from general use in scientific libraries. I request the university, academies, institutes and seminar libraries to carry out the appropriate steps. Regarding the sequestration and restricted use of the journal I refer to my decrees of 17 September 1934, 3 April 1935 and 16 December 1936, UI 22733, W Ie 828 and W Ia 2305.**

The decree is signed by the Imperial and Prussian Minister for Science, Education and Development and no doubt refers to the continuous stream of hostile comment appearing in *Nature* in the mid-1930s, much of it centring around the work of the Academic Assistance Council formed in 1933 to help German academics to find posts overseas. Thus in July 1937, *Nature* (140, 169; 1937) referred to the dismissal of German Jewish academics as the "German disaster" and remarked that it was unlikely that "the leaders of intolerance and irrationalism will be deterred by the knowledge that their victims will be sheltered in the asylum of liberal countries". □

Indian science circus

SIR — While your comprehensive reports on science in India in the issue of 12 April are true and appropriate, I should like to stress some of the basic problems behind the prevailing confusion afflicting the Indian science scene.

Modern scientific education and research struck roots in India during the early twentieth century and rapidly grew after independence. The first scientists who were patronized by the government had their own individualistic ideas on developing science in India, for which most of the equipment had to be imported. Soon after independence, India suffered a shortage of foreign exchange, which hindered the import of adequate support materials, but the number of scientific institutions nevertheless continued to increase. This odd situation led to a lowering of the standards of scientific activity. However, many students could imbibe bookish knowledge and some of them could easily migrate to other countries where opportunities for work were abundant. Thus, Indian scientists are thriving both at home and abroad, but occasional soul-searching goes on and comparisons between home-based and expatriate Indians are sometimes not well chosen.

It requires a great deal of patience and faith to work in Indian conditions, in which even essential items are perpetually scarce. Time and efficiency are of relatively little importance in our country and hero worship, blind or forced, is part of life. Unfortunately, modern technologies need less hero worship and more efficient practice. However, our policy-makers (heroes) are not deterred from buying or borrowing any latest technology, and camp-followers are easily found among our vast multitudes. Thus, India constitutes a country of tremendous contrasts wherein basic facilities such as power supply, telephone and other communications services are woefully inadequate on the one hand, while on the other, huge installations for research in space and biotechnology are being planned without the least hesitation. Just as the highly rich and the abjectly poor exist side by side, so also do high and low technologies. After all, ancient emperors built great monuments like the Taj Mahal, probably employing a starving labour force, and as if to keep up that tradition, our science administrators in the past few decades have also been able to build a few glamorous edifices in the name of excellence.

Our tolerance is a boon, giving us the willpower to live amidst glaring disparities, but it is a bane to the implementation of contemporary developments. Finally, it is another wonder of the world to watch the mystic religious practices that cost next to nothing and modern scientific pursuits at exorbitant costs blissfully coexisting in India!

C. RADHAKRISHNAMURTY

No thanks to. . .

SIR — So you think that the Royal Society "has broken new and dangerous ground" in the acknowledgements by authors of papers published in the society's journals (*Nature* 26 April, p.762). What is so new? And why so dangerous?

The practice of acknowledging help from others goes back a long way, even in this society's history, so it is certainly not new. If authors are now a little more generous and a little less formal than in the past, why is that so dangerous? The law of libel should remind editors not to allow to be printed the sort of remarks that you fear could be dangerous.

A paper in *Phil. Trans.* (1883) concludes "My best thanks are due to Professor Lankester for some excellent specimens of *Paragorgia, Villogorgia* and *Briareus*, and I am also deeply indebted to Professor Mosely who freely placed his numerous preparations at my disposal and whose constant aid and advice have been of invaluable assistance to me." The acknowledgements from *Proc. R. Soc.* (1984) that you quote are in a long and honourable tradition.

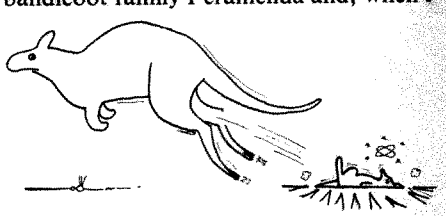
R.W.J. KEAY
Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, UK

● Lankester's organisms are Alcanarians (sea anemones). The more recent acknowledgement that seemed to break new ground read "This research was not supported by any military organization". — Editor, *Nature* □

Publishing chronology

SIR — We read with interest the piece by John Maddox under the title "Extinctions by catastrophe?" (*Nature* 19 April, p.685). The complex of problems produced by the distribution of preprints and by prepublication press coverage is certainly something we should all ponder. It is clear that the system is sometimes beneficial and sometimes not and that there are no simple answers.

In condensing a complex chronology, however, one non-trivial item was left out. In August of 1983, we presented a summary of our research on periodic extinction at a widely attended meeting on the "Dynamics of Extinction", held in Flagstaff, Arizona. The oral presentation was accompanied by a printed abstract as part of the official programme for the Flagstaff meeting. The meeting was attended by several science writers and subsequently *Science* (**221**, 935; 1983), *Science News* (**124**, 212; 1983) and several other publications carried accounts of the meetings that included substantial treatment of our extinction analysis. It was mostly from these accounts that physicists, astrophysicists and geologists heard of our work, and this led to many requests for more information and for preprints. We were unable to send preprints until early October when the manuscript was complete and ready for submission to *Proceedings of the National Academy of Sciences*.



In view of the foregoing, we do not think that the situation leading to the publication of the five papers on extinction in the 19 April issue of *Nature* fits the classic description of scientific communication-by-preprint. Notice of the research results (including the Flagstaff abstract) was available to all readers of *Science* and *Science News* and to all participants at the Flagstaff meeting. Preprints were sent out only later and then were largely limited to those requesting them. Of course, no preprints were released to the press.

We hope that the publication of this letter will clear up any confusion over this curious incident.

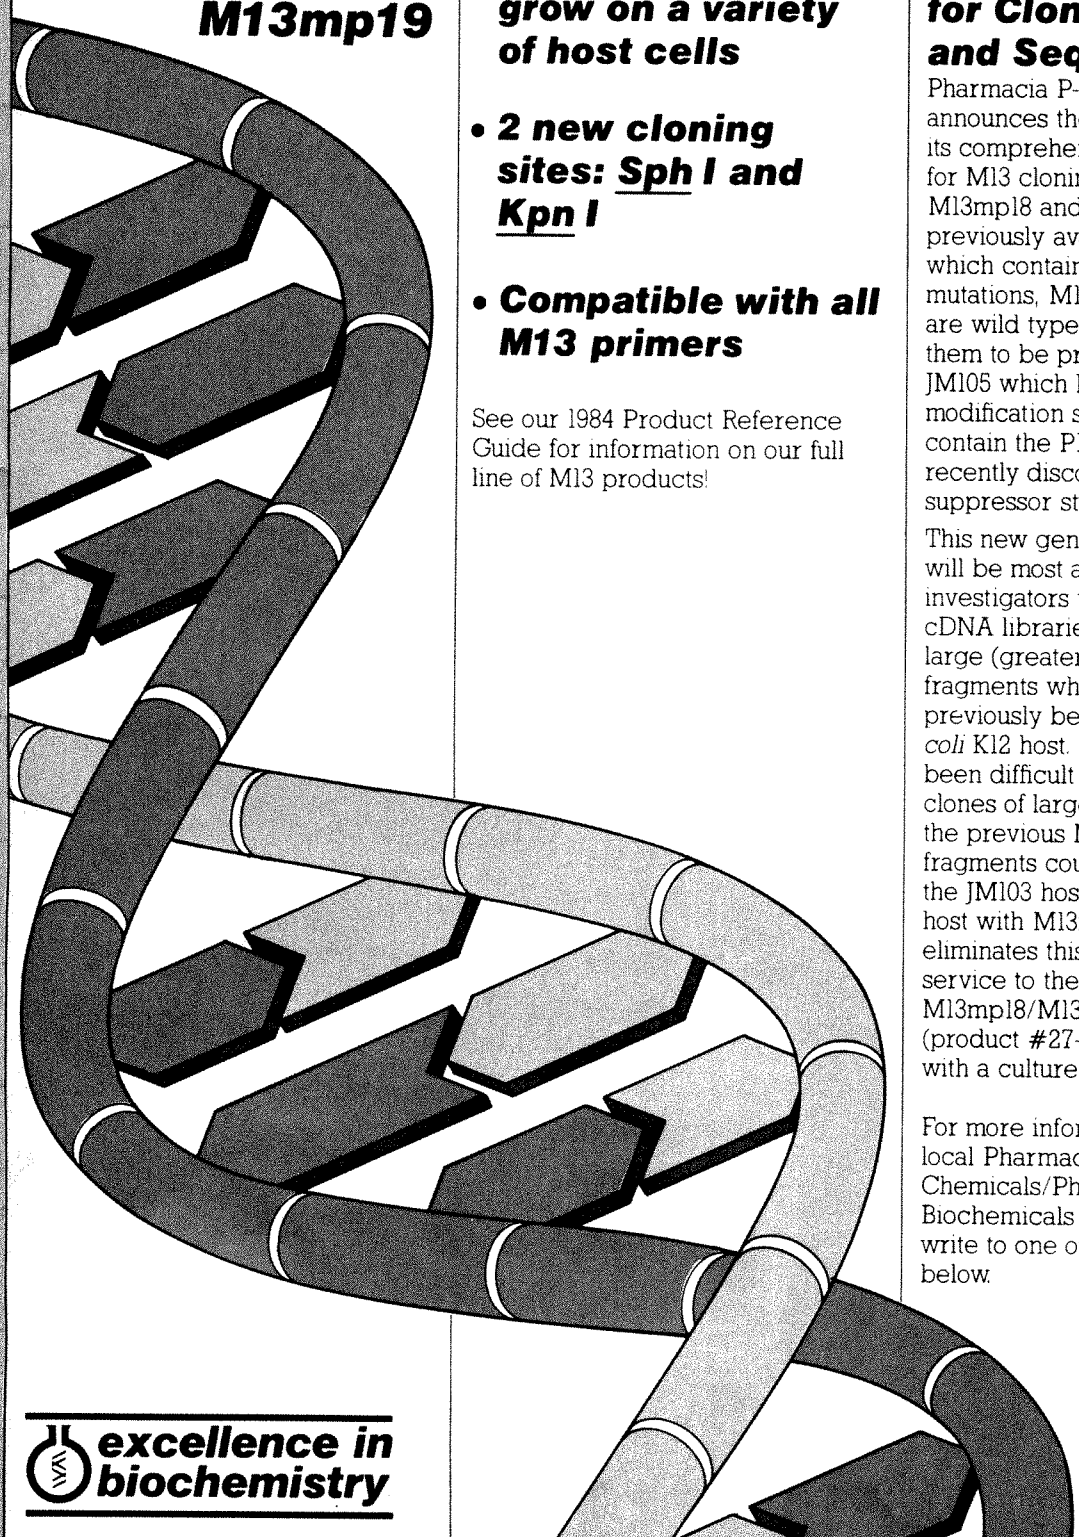
Directional pouches

SIR — I was fascinated by the photographs of a gaping thylacine ("Tasmanian tiger") in the series from Jon Darius's *Beyond Vision* (*Nature* **307**, 411; 1984). However, among the curious features of the thylacine, the rear-opening pouch is by no means unique. According to Walker's *Mammals of the World* (1964), the posteriorly opening pouch is typical of the bandicoot family Peramelida and, when



pouch is present, of the family Dasyuridat. The pouch also opens backwards in the koala *Phasolarctos*, the wombat *Phascolomis* and the marsupial mole *Notoryctes*.

I presume that in most of the quadrupedal marsupials, as in the thylacine, young in a front-opening pouch might be liable to damage by undergrowth, or in the mole, from the pouch filling with soil. Only in the bipedal macropods would a backward — and hence downward — opening pouch have obvious disadvantages.

New Wild Type M13 Vectors From Pharmacia P-L Biochemicals

M13mp18
M13mp19

- **Wild type phages grow on a variety of host cells**
- **2 new cloning sites: Sph I and Kpn I**
- **Compatible with all M13 primers**

See our 1984 Product Reference Guide for information on our full line of M13 products!

New Tools for Cloning and Sequencing

Pharmacia P-L Biochemicals announces the newest additions to its comprehensive line of products for M13 cloning and sequencing—M13mp18 and M13mp19. Unlike previously available M13 vectors which contain double amber mutations, M13mp18 and M13mp19 are wild type phages. This allows them to be propagated on *E. coli* JM105 which lacks restriction and modification systems, and does not contain the P1 lysogen which was recently discovered in the amber suppressor strain JM103.

This new generation of M13 vectors will be most appreciated by those investigators who are constructing cDNA libraries in M13 or inserting large (greater than 1 kb) DNA fragments which have not previously been cloned in an *E. coli* K12 host. It has sometimes been difficult to obtain full-length clones of large DNA fragments in the previous M13 vectors since the fragments could be degraded by the JM103 host. Use of the JM105 host with M13mp18 and M13mp19 eliminates this problem. As a service to the researcher, our M13mp18/M13mp19 vector kit (product #27-1551-01) is supplied with a culture of JM105.

For more information, contact your local Pharmacia Fine Chemicals/Pharmacia P-L Biochemicals representative or write to one of the addresses below.

MICROSCOPY EXHIBITION (In association with Nature)

MICRO 84 is a unique opportunity to examine the latest designs in the modern microscope industry, including instruments and ancillary equipment for both light (optical) and electron microscopy by the world's leading manufacturers. The MICRO series is now established as a regular event and is used by the firms to launch their new products. The MICRO exhibition gives thousands of microscope users the opportunity to see the world's largest selection of microscopes on display under one roof. This exhibition is free, and is not restricted to the scientific delegates attending the conference.

Please write to Sarah Lock at the Oxford address (given above) for your tickets.

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

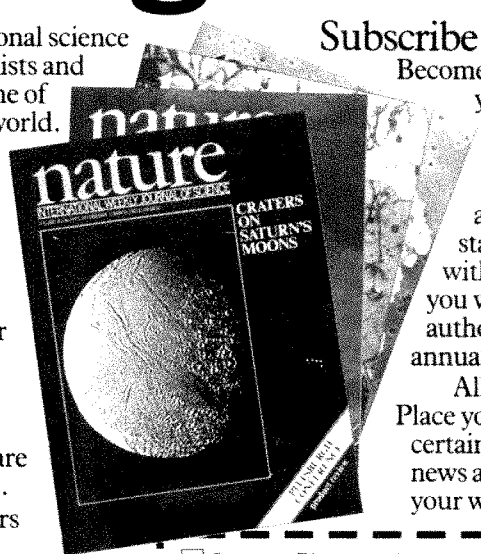
With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews—Eminent figures offer expert judgments on a wide variety of recent publications.



Special Issues providing an in-depth treatment of topics of importance.

Product Reviews—Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now–and save!

Become a personal subscriber now and you will receive a discount of over 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just $2.12 a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when *you* want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special rate of US$110.

☐ I enclose my personal check for US$110 made payable to Nature. (Note: Institutional checks cannot be accepted at this special rate. The institutional price is US$230.)

☐ Please charge to my credit card account.

Anatomy of a pressure group

from Stephen Budiansky

Mr Jeremy Rifkin's assault on genetic manipulation seems to be succeeding. The danger is that he will not be taken seriously.

IF it were not for the prominent names that keep popping up on his manifestos, people would probably ignore Jeremy Rifkin, the self-styled social crusader who hopes to save mankind from genetic engineering. Rifkin's remarkable knack at canvassing for credibility is once again in evidence, in the case now before Judge John Sirica in Washington, DC in which Rifkin is seeking to halt the first field trials of genetically-engineered bacteria. And it is hard to dismiss one who can wave affidavits from respected scientists who appear to support his claims that serious unfathomed risks are lurking behind these unprecedented experiments.

Combining frequent references to his gallery of the famous with a stream of eminently quotable apocalyptica, Rifkin has succeeded in conjuring an image of genuine controversy. The fact that scientific opinion runs virtually unanimously against him and that his "support" from the famous proves time and again to be far less than meets the eye tells much about public relations on complex scientific issues and about the political naivete of too many scientists.

Crop protection

The case now before Judge Sirica deals with an experiment approved by the Recombinant DNA Advisory Committee (RAC) in April 1983 in a decision remarkable at the time only for its seeming total lack of controversy. Two University of California researchers, Steven Lindow and Nikolas Panopoulos, were hoping to demonstrate the ability of genetically-altered bacteria to protect field crops against frost damage. Under natural conditions, certain strains of wild bacteria that colonize the leaves excrete a protein that serves as a nucleation site for ice formation at a temperature slightly below freezing. If it were not for this protein, temperatures could drop as low as eight degrees Fahrenheit below freezing without frost actually forming. Lindow and Panopoulos believe that by displacing these wild bacteria with laboratory bacteria that have been genetically altered so that they cannot produce the protein, the growing season could be extended by several weeks in the spring and fall. A single gene is responsible for the protein, making this an obvious candidate for genetic engineering.

Although the proposal by Lindow and Panopoulos was RAC's first request for permission to release a genetically engineered microbe outside the laboratory, it seemed to raise no real safety questions. The researchers had already performed identical experiments with chemically-mutated bacteria — experiments which, if anything, were more dangerous yet which did not require RAC's approval as they did not involve recombinant DNA techniques. The field tests with the engineered bacteria were to be done at a single site, geographically isolated from California's citrus and fruit crops, and the bacteria were to be pre-screened in a greenhouse against any tendency to damage plants. After hearing the report of an outside consultant, Ann Vidaver, a plant pathologist at the University of Nebraska, and noting that the researchers had altered their experimental proposal in response to minor criticisms made earlier by RAC. RAC unanimously approved the experiments.

The experiments were to begin in November 1983. On 14 September, Rifkin filed suit in US District Court, arguing that RAC's approval was invalid because no environmental impact statement had been filed, a requirement for all federal actions having a "significant" effect on the environment. Rifkin also threatened to file for a temporary injunction against the University of California to halt the field trials pending a ruling on his lawsuit.

Lindow and Panopoulos postponed their experiments until this spring, by which time, they hoped, Sirica would have disposed of the matter. Last week, following Lindow's declared intention to proceed with the experiment later this month, Sirica granted Rifkin a preliminary injunction, halting the experiments until he could hear the full case (see p. 296).

Suing the government, of course, has become standard practice in the environmental movement. Key environmental legislation of the 1970s granted citizens an explicit right to actions; other legislation allows those who sue the government in the public interest to collect attorneys' fees if they win. This mechanism has proved a valuable remedy for foot-dragging by the government and has served to ensure that government agencies follow proper procedures.

But suing the government is also a great attention-getter. In the present case, Rifkin has not taken advantage of repeated opportunities for public participation in RAC's deliberations (saying he was out of town on those days). The nuisance-to-substance ratio of the lawsuit is high — at best, a final decision in Rifkin's favour will require only that RAC go through the formality of producing an Environmental Impact Statement for deliberate release experiments; after that, it can approve whatever experiments it wants without further judicial review. But a barrage of hyperbolic press releases accompany the suit, calling RAC "grossly irresponsible" and accusing it of "reckless disregard for the protection of the environment". In an interview, Rifkin said that the release of genetically-engineered organisms to the environment may "deplete the life-support system of the planet".

Scientists' support

Such statements, of course, make good copy. They also make scientists groan. But Rifkin's ace is the collection of experts he has corralled. "You can dismiss me", he says when challenged about the soundness of his more extreme comments, "but it's very hard to dismiss Peter Raven".

Peter Raven, director of the Missouri Botanical Garden, professor at Washington University and member of the National Academy of Sciences, is probably the most prominent name on Rifkin's list of scientific supporters. His affidavit, like the others, speaks mainly in generalities about the dangers of introducing new species into established ecosystems, and seems to betray an ignorance of the details of the Lindow experiments.

Remarkably, Raven freely admits that he had seen neither the detailed experimental proposals nor RAC's minutes before filing his affidavit. And he said, "I'm not criticizing RAC at all. I haven't even got a position more than to say we need visible discussion." Asked why he did not use RAC's public meeting or the nearly year-long opportunity to file comments with RAC, he said he had "no way of knowing" how he could participate in RAC's deliberations. "Nor was my opinion sought." Raven said the burden must be on RAC to reassure the ecological community that adequate scrutiny was given to the proposal.

Eugene Odum, an ecologist at the University of Georgia, also filed an affidavit. He said he was voicing his concern over the lack of proper procedures for evaluating deliberate-release experiments, not the Lindow experiment itself. "I would doubt that the experiment itself is dangerous", he said, "but it could establish a precedent that's very dangerous."

Yet the procedures are already in place for evaluating deliberate-release experiments. Maxine Singer, a researcher at the National Institutes of Health (NIH) who has been a strong voice for caution since 1973, says that tactics such as Rifkin's lawsuit are unlikely to bring about a more thorough scrutiny of genetic engineering research. "The evidence is there that RAC asks difficult questions and is not about to give permission at the snap of their fingers", she says. And everyone, from Jeremy Rifkin to the biotechnology industry, agrees that, although compliance with RAC's decisions is technically voluntary for private industry, no company would dare proceed without RAC approval, since a company's failure to abide by the guidelines and RAC's decisions would be very damaging evidence of negligence if the company were sued for damages arising from an experiment. And Singer doubts whether the Environmental Protection Agency could command the political clout and scientific respect of RAC.

David Baltimore of Massachusetts Institute of Technology speaks for many when he says that "there are aspects of the direct-release experiments that raise problems that RAC previously didn't have to deal with. But I don't think it's helpful to make generalizations. You have to think carefully about each case. You can't do it on the basis of what you hear from Jeremy Rifkin or what you read in the *New York Times*." And he warns of the dangers of a backlash against Rifkin's tactics: "The continual opposition to recombinant DNA activities has made the scientist community leery of raising even those concerns they feel are legitimate, because they can so easily be taken advantage of. And that's a terrible climate. But it's the inevitable consequence of politicization."

Endangered humanity

This lawsuit is not the first occasion that Rifkin has pulled credibility out of a hat. Last June, after canvassing religious leaders across the country, Rifkin produced a petition calling for an "immediate" ban on engineering of the human germ line. Joining the call were 21 Catholic bishops, leaders of most major protestant sects in the United States, several Jewish leaders, the Moral Majority's Jerry Falwell and television preacher Pat Robertson. A "theological letter" accompanying the position provided the apocalyptic rhetoric — calling engineering of genetic traits "a fundamental threat to the preservation of the human species as we know it". The letter claimed that "it will soon be possible to carry out such procedures on humans, and argued that even the elimination of defective genes — such as those responsible for sickle-cell anaemia — would dangerously narrow the human gene pool and "might ultimately lead to the extinction of the human race".

Rifkin concluded by equating genetic engineering with eugenics ("the inseparable ethical wing of the Age of Biotechnology") and by calling upon society to oppose human genetic engineering "with the same courage and conviction as we now oppose the threat of nuclear extinction".

Once again, there was less than met the eye. The religious leaders who appeared at Rifkin's New York City press conference were careful to disavow the "theological" letter; they had signed only the much more moderately-worded petition. Subsequent interviews revealed that many of the signatories had minor or even major reservations about the petition as well. Some said they did not oppose treatment of disease, and had signed only to express their agreement with Rifkin's warnings about the misuse of genetic engineering for eugenics. Many reaffirmed their support for somatic-cell gene therapy for the relief of human suffering and the treatment of disease.

Once again, Rifkin may also have alienated those who might otherwise have been his natural allies. Alexander Capron, who directed the President's Commission for the study of Ethical Problems in Biomedical and Behavioral Research — which, until its demise last year, produced a series of carefully argued and widely praised studies of ethical issues in medicine, including genetic engineering — called the petition a "knuckleheaded, broadside" attack that swept aside a host of subtle ethical dilemmas in favour of polemics.

John Fletcher, an Episcopal minister who, as assistant to the director of NIH for bioethics, has thought long and hard about these issues, was also irked by the petition. He wrote to Bishop John Allin, the presiding bishop of the Episcopal church in the United States and a signatory of the petition, criticizing its "apocalyptic" tone and its failure to take into account the "thinking that had already been done". Fletcher said he wishes the signatories had "asked for help to become informed on the body of debate that already existed. It is interesting that the President's Commission report [*Splicing Life*, produced at the request of the major religious organizations in the United States] had existed for a year, and many [of the petition's signers] had not seen it."

Fletcher, significantly, is one of those who have urged caution in proceeding with germ-line alterations, arguing that society at present lacks the necessary ethical and moral system to deal with the consequences of man's engineering his own heredity. "But I am in favour of keeping an open mind", he said.

Others point out that "this is not something that is happening suddenly", as Dr French Anderson, chief of the Laboratory of Molecular Hematology at NIH and a leading researcher on genetic blood disorders, put it. Anderson says although the genes necessary for treating some 20 inherited disorders have been isolated, "we can't get them into the target cells, we can't regulate them properly and we have no way of assessing their safety" in humans. When it becomes a scientific possibility, the real ethical questions may have little to do with somatic versus germ-line alterations but — as pointed out by the President's Commission report — whether the alteration is reversible (should some unforeseen danger later arise), whether it is aimed at correcting recognized genetic disorder or at "perfecting" humans.

Regulation

In the United States, the regulatory mechanism is also already in place to assure that germ-line manipulation is not rushed into without considerable deliberation. Experiments on human subjects will have to be cleared by a local Institutional Review Board charged with protecting human subjects; the board must include at least one non-scientist and at least one scientist not affiliated with the institution. Human gene therapy trials would also have to be cleared by a similar local panel, the Institutional Biosafety Committee, charged with overseeing recombinant DNA research. The full RAC would then have to give its approval and, before it could be applied routinely in clinical practice, the Food and Drug Administration would have to approve its safety and effectiveness.

The case of Martin Cline, a researcher at the University of California, Los Angeles, who performed unauthorized (and unsuccessful) gene therapy experiments on two patients suffering from beta-thalassaemia, a fatal genetic blood disorder, was ample proof that these regulations are not merely cosmetic. When Cline's experiments became known he was stripped of federal research grants and found his research career effectively ruined.

Just as with his lawsuit, the net result of Rifkin's petition may have been polarization — and a backlash against sensible proposals. Congress, for example, is seriously contemplating the establishment of an advisory body, along the lines of the President's Commission, to monitor developments in human genetic engineering. The concept, championed by Representative Albert Gore, is strongly backed by the President's Commission itself, Capron, Fletcher and many others concerned about the ethical and religious implications of genetic engineering.

RAC, the other logical body to exercise oversight on human genetic engineering, has also recently proposed expanding its membership beyond researchers and physicians to include ethicists.

But, as Capron says, there is a danger that those in research and industry who might otherwise support these proposals may come to see them as "part of the Rifkin attack". The danger is that the very concerns that Rifkin claims to represent may be swept aside, resulting in an all-out political battle between two polarized camps. □

Chaos — a model for the outbreak of war

from Alvin M. Saperstein

The chaos as formulated for physical dynamic systems is applied to a very simple nonlinear model of the arms race. The transition, from stability to instability, from arms race to war, could be analogous to the transition from a laminar to a turbulent (or chaotic) flow.

SIMPLE mathematical models of the arms race have aroused interest among academic physicists[1]. Two common models are the dynamic model of Richardson[2,3] and the static inequality model of Kaye[4,5]. Both are deterministic: given the model and its parameters, a reasonable estimate of present conditions allows prediction of the future outcome of the arms race. Here I offer the beginnings of another model based on recent advances in the understanding of chaotic motions of dynamical systems[6,7]. I suggest that war be viewed as a breakdown in predictability: a situation in which small perturbations of initial conditions, such as malfunctions of early-warning radar systems or irrational acts of individuals disobeying orders, lead to large unforeseen changes in the solutions to the dynamical equations of the model. There is no way then to predict the effect of the actions of any participant — analyst, planner, statesman or general — with any certainty. Certainly war, between roughly equivalent parties, has often been characterized by uncertainty in outcome[8]; nations which start wars in great confidence very often end defeated[9]. Typically, in the period immediately before the outbreak of a war the nations attempt desperately to claw back as they slide over the precipice, although they by this time already have lost control of their own destinies[10]: control and predictability are lost.

There is a current view that entrance into war, and the war itself are deterministic — escalation, up or down, nuclear or otherwise, can be controlled[11,12]. But most historical evidence and contemporary analysis indicates otherwise: predictability and control are lost at the threshold between peace and war[13], just as they are lost when a fluid makes the transition from laminar to turbulent flow.

Here I sketch the meaning and development of chaos in nonlinear dynamical systems and apply these concepts to a simple nonlinear arms race between two nations. Both the model and the illustrative parameters are admittedly over simple and do not as yet apply to the real world, but I hope that the concept of 'chaos', as used herein has a bearing on the present world situation. I believe that nonlinear dynamical models, with their capability for both predictable and non-predictable orbit through the phase space of international competition, are necessary for realistic understanding of the present arms race.

Deterministic models patterned after those used successfully in physics have previously been applied to the description of competition in economics and biology[14]. Because these models may also have a significant nonlinear component, it follows that 'chaos' may also result from these competitions; some examples have been reviewed by May[7].

Richardson's model for the arms race between two competing states consists of a pair of coupled first-order linear differential equations. The independent variable is time and the dependent variables are measures of the devotion of the two societies to hostilities — expenditure on arms, percentage of population in the military, and so on. The coupling terms, the off-diagonal elements of the matrix of the system of differential equations, represent the reaction of each nation to the challenge of the other: thus the rate of change of the armaments of nation A is assumed proportional to the total armaments of nation B and vice versa. The diagonal terms of the system represent the intrinsic reaction of each nation to its own armaments; for example, a large military establishment might successfully press for further increases in military expenditure, or the rest of society resist increases in the share of resources going to the military.

The solutions of such a model system are simple linear combinations of exponentials in time. The exponents are determined by the model parameters whereas the coefficients of the linear combinations are uniquely determined by the initial conditions. Small changes in the initial conditions imply small changes in the coefficients, so that two solutions which start very close together will always remain comparatively close together. This is the sense in which the behaviour over time of a dynamical system is predictable. Knowledge of initial conditions is always uncertain, which means that a set of orbits, or a 'flow', is allowed by any practical model. Since all orbits in the Richardson model flow remain close to each other, practical predictions remain possible.

If the model parameters are such that the exponents are negative, the solutions damp down to an equilibrium value no matter how starting conditions are chosen. Such a case is 'stable'. If the model parameters imply positive exponents, the flow departs exponentially from any starting conditions and the armaments of both parties increase exponentially. This situation is 'unstable' and may imply war or the certainty of eventual war.

A peacemaker in Richardson's model must alter the parameters of the competition so that only negative exponents are possible. If he accomplishes that, he can successfully predict peace (or at least inventories of the tools of war which do not grow) no matter what the starting configurations are. Conversely, if the parameters of the model lead to instability, the generals can know what to expect, given reasonable intelligence of the starting configuration.

The Richardson model is dynamic, relating changes in the configuration to a present configuration, and stability or instability to the kinds of change possible. By comparison, the Kaye model of bilateral strategic deterrence[4,5] is static, dealing with the two parties' perceptions of their situation. The variables are the numbers of nuclear warheads each is capable of firing at the other, the model parameters are the dependability, accuracy and destructive capabilities of these warheads. There is no time parameter or variable.

Given one set of inequalities between the variables, one side can punish the other without undue loss. That side is, therefore, secure and can afford to relax; the other side perceives no such security. Given another range of inequalities between the same variables, both sides are assured that they can inflict unacceptable damage upon their opponents even after suffering the worst first-strike devastation their opponent is capable of delivering; both sides perceive 'mutually assured destruction' so have no incentive either to launch a first strike or radically to change their present state of armament. This represents 'stability' or 'stable deterrence' in the Kaye model. Finally, the range of inequalities remaining includes the situation where each side can destroy the other so that the side that strikes first can prevent its victim from retaliating: each side has an incentive to strike first or radically to increase its armaments. The situation is unstable or is said to represent 'unstable deterrence'.

The Kaye model is described by a Cartesian plot in which the two orthogonal axes represent the number of warheads or launch vehicles available to each of the two sides. The inequalities are represented by different regions of the plot. For example, in Fig. 1, adapted from ref. 5, the number of

launch vehicles possessed by side A, N_A, is plotted against N_B, the corresponding number for the opposing side B. In the region designated DA, A is dominant; it can punish B with a successful disarming first strike without fear of severe loss to itself. Similarly B is dominant in region DB. Region MAD is the stable region of mutually assured destruction whereas FS is the unstable deterrence region in which each side has the incentive to strike first. The remaining region, IN, represents that in which neither side has sufficient warheads to do conclusive damage to the other. Thus there are stable and nonstable areas which, topologically are simply connected and have simple boundary curves. Except for the boundary curves themselves, nearby points in the plot belong to the same region. Thus small uncertainties about the actual numbers need not lead to changes in the perception of stability or instability. In this sense, the static model also permits practical predictions.

In physics, we are accustomed to assuming predictability based on Newton's equations of motion. Given the forces, specific initial conditions lead to specific well-defined orbits in an appropriate phase or coordinate space. Similar concepts lead to the nonlinear equations of fluid dynamics. Since actual fluid motions exhibit both laminar and turbulent flows, we must accept that the solutions of the equations of fluid dynamics may represent either laminar or turbulent character and that the nature of the flow changes from laminar to turbulent as some parameter or combination of parameters increases through some critical value[15].

Laminar flow implies predictable behaviour: streamlines which start off near to each other remain near to each other. Knowledge of the motion at one point in the flow at one point in time implies knowledge of the motion at neighbouring points in space and time. Turbulence, by contrast, is chaotic: knowledge of the motion at one location at one time says nothing about the motion at nearby points at the same time or at the same point at later times: prediction is fundamentally impossible. Hence the same mathematical model (the same set of equations) allows predictable behaviour in some regions of a model parameter, and unpredictable behaviour in others. This breakdown of predictability in certain systems seems a good characterization of war in those systems.

Civil life presupposes a major component of predictability. The formulation and carrying out of policy requires a reasonable ability to predict the future given some knowledge of the present. The same requirement for predictability holds for the relationships between nations, whether they are engaged in normal international competition or in a hostile arms race. But the history of nations is full of examples of a loss of control, by one or more governments, as they make the transition from peace to war. Thus any single model of an arms race between nations should include regions of predictable behaviour, regions of chaos and transitions between such regions.

As a simple model of the transition from predictability to unpredictability consider the flow represented by the sequence of mappings[6]:

$$x_{n+1} = 4bx_n(1-x_n) = F_b(x_n) \qquad (1)$$

where $0 < x_n < 1$, $n = 0, 1, 2 \ldots$ and $0 < b < 1$. A specific orbit is the succession of values $x_0, x_1, x_2 \ldots$ starting from a specific value of x_0. A flow consists of a set of orbits, starting from a set of neighbouring values of x_0. The flow is predictable if its constituent orbits remain near each other; it is unpredictable (chaotic) if they drift apart exponentially: if, given any x_0 and x_0 , the difference between x_n *and* x_n diverges exponentially as $n \to \infty$. No matter how small the subinterval ε is from which a chaotic flow starts, it soon fills the entire interval (0,1); no matter how accurately the starting value x_0 is measured if the motion is chaotic knowledge of the position of x_n is soon lost — it is distributed with equal probability throughout the allowed region (0,1). Prediction is impossible for a chaotic flow: the flow determined by (1) above changes from predictable to unpredictable as b increases through the critical value $b_c = 0.892$.

Let x^* be a fixed point of a flow, F, defined by the equation

$$x^* = F(x^*) \qquad (2)$$

Then x^* is a stable fixed point if

$$F'(x^*) = \left| \frac{d}{dx} F(x = x^*) \right| < 1 \qquad (3)$$

If x^* is a stable fixed point, it is easy to see[6] that all orbits, no matter where started, tend to x^* as $n \to \infty$. Thus given such an x^*, perfect prediction is possible: wait long enough and any flow converges to x^*. It is easy to show that $x_b^* = 0$ is the only stable fixed point of F_b for $b < \frac{1}{4}$. For $\frac{1}{4} < b < \frac{3}{4}$, the only such point is $x_b^* = 1 - (4b)^{-1}$. And for $b > b_1 = \frac{3}{4}$, there is no stable fixed point of $F_b(x)$.

Consider now the mapping $F_b^{(2)}(x) = F_b(F_b(x))$ and its fixed points x_b^{**}. If x_b^{**} is not a fixed point of F_b, it follows that

$$F_b(x_b^{**}) = \bar{x} \text{ and } F_b(\bar{x}) = x_b^{**}$$

where $\bar{x}$ does not equal x_b^{**}, (note that x is also a fixed point of $F_b^{(2)}$). Thus $x_{n+2} = x_n$, $x_{n+1} \neq x_n$, if $x_n = x_b^{**}$. It follows that the flow F_b oscillates back and forth periodically between pairs of stable fixed points of $F_b^{(2)}$, if these exist while those of F_b do not. Such a situation occurs for $\frac{3}{4} = b_1 < b < b_2 = 0.862 \ldots$ Again, prediction is possible, though more complex.

For $b > b_2$, the fixed points of $F_b^{(2)}$ are no longer stable, so that it is no longer possible to say that the flow converges to a periodic oscillation between two points. But there is now an interval $b_2 < b < b_4$ for which the fixed points of $F_b^{(4)}(x) = F_b^{(2)}(F_b^{(2)}(x))$ are stable. The flow now converges to a periodic oscillation between four points. Prediction is still possible though even more complicated. As b increases further, the fixed points of $F_b^{(4)}$ become unstable, the four-point periodic motion disappears and the flow now converges to an eight-point cycle, which then becomes a 16-point cycle and so on.

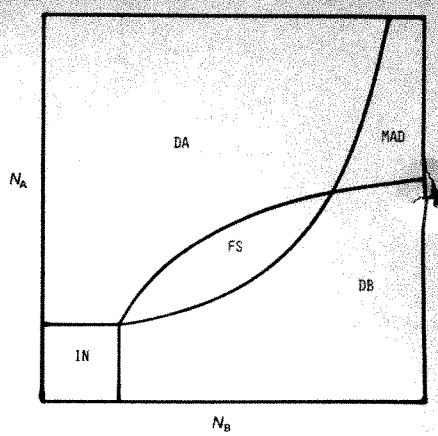

Fig.1 A strategic balance diagram (Kaye plot) showing regions of stability and instability.

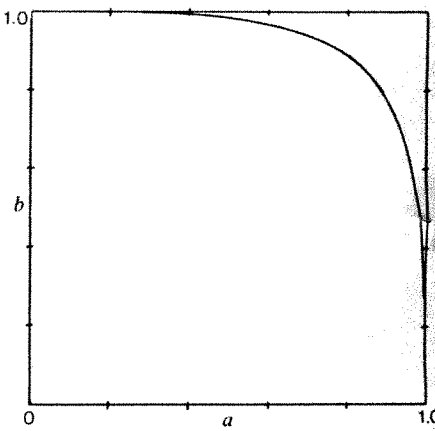

Fig.2 A curve representing $f_4(a,b) = 0$ (see text), taken to be a reasonable approximation to the critical curve $f_c(a,b) = 0$ separating the region of predictability from that of chaos. Data courtesy of Larry Dishman, Wayne State University.

There is thus a sequence of periodic oscillations of ever-increasing complexity corresponding to a sequence of transition values b_i with an accumulation point at $b_c = 0.892 \ldots$ Beyond this value lies chaos: orbits do not have definite end points, initially neighbouring orbits diverge exponentially, any flow soon fills the entire interval and prediction is impossible. In this simple model, b_c corresponds to the critical Reynold's number which governs the transition to fully turbulent fluid flow.

A bilateral arms race between two competing countries X and Y is assumed to occur in stages designated by an integer indicator n; successive values of n may indicate successive years, successive budget cycles and the like. (Thus n is a discrete version of the independent variable, time, in the Richardson model.) The dependent variables x_n, y_n represent the fraction of the two nations' resources devoted to armaments: $0 < x_n, y_n < 1$. A nation's armaments at the next stage depend upon its perception of its opponent's armaments at the present stage; I will assume x_{n+1} to be proportional to y_n and conversely.

Table 1 Ratio of national military expenditure to GNP

	France	Germany	Italy	UK	USSR
1934	0.0276	0.0104	0.0443	0.0202	0.0501
1935	0.0293	0.0125	0.0461	0.0240	0.0552
1936	0.0194		0.0298	0.0296	0.0781
1937	0.0248		0.0359	0.0454	0.0947

But the perceived threat also depends upon how much of the opponent's resources remain potentially convertible to armaments at a future stage. If all of the opponent's substance is devoted to arms, there is no need to be concerned about a future increase in threat (assuming fixed total resources). Hence I also assume x_{n+1} to be proportional to $1-y_n$ and conversely. My simple arms race model thus consists of the pair of sequences of mappings:

$$x_{n+1} = 4a\,y_n(1-y_n) = F_a(y_n) \quad (4)$$

$$y_{n+1} = 4b\,x_n(1-x_n) = F_b(x_n) \quad (5)$$

in which $0 < a, b < 1$. If the values of a and b are such that the flows are predictable the race will be said to be stable. Each party will know what the future portends and can plan accordingly. If the parameters product a chaotic flow, the race is unstable and neither can know what the future will bring.

Analysis of the model with two parameters and two variables represented by equations (4) and (5) is similar to that of equation (1). Fixed points are characteristic of the mapping of a variable onto itself. Thus in this case the appropriate sequences of mappings are not F_a and F_b but, instead,

$$F_{ab}(x) = F_a(F_b(x)) \text{ and } F_{ba}(y) = F_b(F_a(y)) \quad (6)$$

Fixed points of these sequences imply $x_{n+2} = x_n$ and $y_{n+2} = y_n$ and are again stable if the absolute magnitude of the derivative is less than unity. It is easy to show that, for each fixed point x_i^* of F_{ab}, there is a corresponding fixed point y_i^* of F_{ba}; with $y_i^* = F_b(x_i^*)$ and $x_i^* = F_a(y_i^*)$. Further, if one of the pair of fixed points is stable, then so is the other since the two slopes are equal. A similar relationship connects the fixed points of $F_{ab}^{(2)} = F_{ab}(F_{ab})$ and $F_{ba}^{(2)} = F_{ba}(F_{ba})$, and so on. Hence, there cannot be predictability in one of the variables and unpredictability in the other. Both parties to the arms race will be at war or at peace simultaneously, which corresponds with commonsense.

Again, as the values of a and b are changed, there is a sequence of flows in which first the fixed points of F_{ab} and F_{ba} are stable; then these fixed points become unstable while those of $F_{ab}^{(2)}$ and $F_{ba}^{(2)}$ remain stable; these then become unstable while the fixed points of $F_{ab}^{(4)} = F_{ab}^{(2)}(F_{ab}^2)$ and $F_{ba}^{(4)} = F_{ba}^{(2)}(F_{ba}^{(2)})$ remain stable, and so on. Instead of a sequence of transition points b_i and a critical accumulation point b_c, as above, there is now a sequence of transition curves $f_i(a,b) = 0$ (symmetric in a and b) and a critical accumulation curve $f_c(a,b) = 0$ beyond which the two flows are chaotic.

The actual transition values, a_i, b_i, for the model of equations (4) and (5) have been estimated graphically. Plots were made, for a sequence of values of a and b, of $F_{ab}(x)$, $F_{ab}^{(2)}(x)$, $F_{ab}^{(4)}(x)$. Intersections with the straight line $F(x) = x$ were determined and the slopes F_{ab}, $F_{ab}^{(2)}$, $F_{ab}^{(4)}$ were measured by eye. A transition was judged to have occurred when the absolute magnitude of one of the slopes exceeded unity. Given the crudeness of these measurements, the critical accumulation curve is assumed to be indistinguishable from the curve $f_4(a,b) = 0$ which determines the transition of $F_{ab}^{(4)}$ from stability to instability and which is sketched in Fig.2. Chaos, and hence war, occurs for those values of the model parameters a, b lying above and to the right of the curve.

It is tempting to apply this model to previous and present arms races even though the data are difficult to obtain and the model is over-simple. Some data are available for the period immmediately preceding the Second World War[12], although the figures are questionable. Nevertheless, it is possible to assign values for the ratio of national military expenditure[16] to gross national product (GNP)[17] (Table 1).

The values in Table 1 are x_0, y_0, x_y, and y_1 (subscripts 0 and 1 designate the earlier and later of the two years used) to be substituted into equations (4) and (5) to obtain parameters a and b for pairs of competing countries in the European arms race during the 1930s (Table 2).

Table 2 The parameters a and b

		a	b
France–Germany	(1934–35)	0.712	0.116
France–Italy	(1936–37)	0.214	0.472
UK–Germany	(1934–35)	0.582	0.158
UK–Italy	(1934–35)	0.142	0.582
USSR–Germany	(1934–35)	1.34	0.0657
USSR–Italy	(1936-37)	0.819	0.125

Thus the German–Soviet arms race was in the chaotic region, and the French–German and Italian–Soviet races were clearly close to the transition region. We all know that the Second World War broke out shortly thereafter, but it is difficult to give much credibility to this *post hoc* calculation because the model is purely bilateral.

Turning to the present-day arms race between the United States and the Soviet Union, I assume for the sake of illustration that 7 per cent of the US GNP is devoted to military and associated expenses, so that $x_0 \approx 0.07$. Assuming that Soviet armament expenditure is comparable with that of the United States and that Soviet GNP is roughly half that of the United States, it follows that y_0 0.14. Given the crudeness of the numbers and the model, it is reasonable to assume $x_1 \approx x_0, y_1 \approx y_0$ from which it follows that $a \approx 0.15$, $b \approx 0.54$. Thus the Soviet–American arms race at present lies within the stability range of Fig.2. Instability develops when b (or a) approaches unity; this would occur if y_0/x_0 increased from two to between three and four. Given the crudeness of the model and choice of parameters, no comfort can be drawn from this last statement. A more realistic model may require more than one dependent variable for each side. With such additional variables the threshold to chaos may be lower.

The crude model presented here is not a credible representation of world affairs. At the very least, it should be expanded to include the equivalent of Richardson's diagonal terms: the direct affect of x_n upon x_{n+1}, of y_n upon y_{n+1}. Also required is a careful determination of the model parameters, the a and b of the off-diagonal terms as well as corresponding coefficients for the diagonal terms[18,19]. This latter task would require the accumulation of data for arms expenditures and GNP over a sequence of several years, a task made difficult by the lack of Soviet data comparable in definition and quality with the generally available US data[20,21]. There is also the problem of the definition of military expenditure in today's high technology world.

Thus any realistic model of a two-party arms race will most probably include nonlinear terms as a result of which there may be a transition from a predictive state of affairs to chaos. The creation and analysis of such chaos-predicting models and the practical applications of the insights they provide can contribute to avoidance of such chaos in real life. □

Particle people compile data

The latest compilation of particle physics data is a monument not merely to those who discover new particles but also to those who have improved the accuracy of what is known.

THE complaint that there are simply too many material particles for any of them to justify the old adjective "fundamental" may seem, on the face of things, to be fully borne out by the latest compilation of properties by the Particle Data Group, a collaboration of 23 physicists which is an international outgrowth of the old Berkeley Particle Data Group on which responsibility for a critical review of available data used to rest. The new compilation, based on data which had become available by the end of 1983, runs to 304 pages of the *Reviews of Modern Physics* for April this year (**56**, S1–S304; 1984) and is likely to be many people's bible for years to come. It is also a model of how data should be compiled in a fast-moving field. The moral seems to be that the job is best done by people who are themselves practitioners.

In reality, the compilers have had to break with the traditions of their predecessors and now explain that they can no longer include references to all relevant publications in high-energy physics bearing on the properties of particles. The literature, they say, is growing by about 10 per cent a year, with the result that archival material must rest where it lies, in previous compilations, the most recent of which was two years ago. Laconically, however, the new list of particles includes (under "stable particles", if you please) the measured values of the masses of the W and Z particles first discovered just over a year ago at CERN, the European high-energy physics laboratory.

The classification of these particles (along with the photon) as stable is not as eccentric as it may seem. The criterion is that particles whose decay is accomplished only by the intervention of weak nuclear forces are counted as being stable. By the same test, a whole string of unstable mesons and baryons are thrown together in the same group.

To outsiders, perhaps the most surprising feature of these listings is the comparative speed with which it seems to have been possible to refine the accuracy of the masses of recently-discovered particles. Thus, among the group of three known leptons (electrons, μ-mesons and τ-mesons, each with negative or positive electric charge), the masses of the first two are understandably known to within one part in a million (after eight and four decades respectively), but even that of the τ-meson is known to within 2 parts in 1,000 after less than a single decade. Among particle physicists, it must be tempting to hope for a further order of magnitude in the accuracy with which the mass of each particle is known with the passage of each decade. But this can only be a rule of thumb; the estimated mass of the first strange meson (K), discovered more than thirty years ago, is hardly more precise (at one part in 50,000) than that of the J/ψ, just over a decade old and the first experimental proof that charmed quarks do indeed exist.

In the circumstances, it is something of a surprise that while the mass of the neutron is known (as it should be after all this time) to better than one part in a million, the lifetime of this particle against radioactive decay (into a proton, a negative electron and an antineutrino) is known only to within 2 per cent or thereabouts.

This is not, of course, the scandal that it may seem to be. The experimental difficulties of anything like a direct measurement of a decay whose products are among the most common particles in the real world, and — worse still — themselves stable, are bound to be formidable. But the practical importance of knowing the decay rate of neutrons is far from negligible even in such straightforward circumstances as the production of bursts of cosmic rays from the Sun.

On the lifetime of the proton, the new compilation of particle data is also necessarily unhelpful. The authors can only quote the steadily lengthening list of largely negative searches for evidence that protons do indeed decay, as the grand unified theories uniting electromagnetic, weak and strong forces suggest they should, into, say, electrons and photons. As is well-known, the lower limits on the lifetime determined experimentally are already less than the lifetime calculated by the simplest of the theories, according to this compilation by "at least one order of magnitude". Given that the first experimental data appeared only in 1981, and that nearly a score of substantial papers on the subject have since appeared, it cannot be much more than a year before the decay of the proton is observed, or the theories put in considerable difficulty.

Another of the still-fruitless searches reported in the compilation is that for the sixth quark, labelled *top*. By now, it seems thoroughly established that the particles called mesons consist simply of a quark and an antiquark, not necessarily of the same breed. In retrospect, it is clear that the most familiar mesons (the muon and pion) and the less massive of the two strange particles discovered in the late 1940s are made only of the three quarks called *up*, *down* and *strange*. *Charm* was found at Stanford University a decade ago, and *bottom* soon afterwards, but *top* remains to be discovered.

This latest compilation of particle data has surprisingly little experimental evidence to report, all of it dating since 1981. And much of this is entirely negative — people have looked for particle resonances over a range of energies and have found nothing to suggest the existence of a *top* quark. But there is a handful of papers that appear to conclude that something happens at an energy of about 34 GeV which could be the signature of the species called toponium, a particle built from the *top* quark and its antiquark. If that is the case, the proton–antiproton collider at CERN should find *top* any day now. Some would say that the missing quark should have been found already.

Even in this dry listing, the search for free quarks is more fun — but equally fruitless. In a listing of more than 250 experimental searches (each of which is solemnly accompanied by a number giving the number of "quark events" recorded), all but a few of the corresponding entries consist simply of the digit "0". The experiments cover both searches for free quarks in accelerator experiments and those, based on the assumption that free quarks could be relatively massive and stable particles, in which people have sought to find quarks by taking vacuum cleaners to the ground beneath electrified security fences. The commentary in the compilation says that "of the several candidate cosmic ray events, one still enjoys the active advocacy of its discoverer".

Other particles have been sought and not found in great profusion. On the evidence of this listing, the magnetic monopole does not exist. From the exotic zoo of particles such as the Higgs boson (which *should* exist if only people knew where to look) and the tachyon (which entails time-reversal), the axion is singled out for special attention in this compilation, no doubt because of the recent popularity of these still unknown particles as plausible constituents of the missing mass in the Universe. But here again, for the time being at least, the experimentalists have drawn a blank.

Auditory physiology

Mobile maps in the brain

from John D. Pettigrew

POINT-to-point matching of an array of sensory cells to an array of central neurones produces retinotopic and tonotopic maps in the brain, which have been the stock in trade of neuroscientists tackling problems such as the control of neuronal specificity. But a neural map of auditory space cannot be generated simply by the equivalent topographical projection from the cochlea at the auditory periphery, because the cochlea represents the frequency of the tonal sound stimulus rather than its location in space. Instead an auditory space map must be computed from subtle cues provided from the effect of the head and pinna on the sound field. It therefore came as a revelation to find a 'computational map' f auditory space in the brain of the barn wl, where individual neurones are specifically tuned to different sound source locations and are arrayed so that position in the brain map is systematically related to the preferred location in space[1]. The mechanism by which such a map is generated is still being explored, but meanwhile a study of an auditory space map in the monkey's midbrain has produced another revelation, reported by Jay and Sparks on page 345 of this issue[2].

Jay and Sparks find that single neurones in the monkey superior colliculus show specificity for the azimuthal location of a sound source and are arranged topographically to form a map of sound space somewhat like that described in the owl, but with one feature that is new and surprising: the coordinate frame of the map shifts along the horizontal plane as the monkey's eyes change position. Thus, for example, a neurone which responds to a sound source located 10° to the right of the eye's fixation point when this is straight ahead will still respond to a source located 10° to the right of the fixation point when the eyes are looking 40° right, even though the head and ears have remained stationary.

The new findings have come from conceptual and technical innovation in the presentation of sound stimuli, which auditory neurophysiologists have at last moved from the ear-canal out into free-field auditory space. This move, like that made by visual physiologists in the late 1950s away from direct retinal stimulation towards the use of natual visual stimuli[3,4], avoids assumptions about the way in which complex spatial parameters of the natural stimulus are encoded; and it is proving to be as fruitful in audition as it was in vision.

One of the first free-field auditory stimulators used by auditory neurophysiologists was called Herb's Hoop, after the Caltech craftsman who built it while also working on equipment for the Viking spacecraft. Appropriately, the hoop was initiated on the same day in 1976 that the Viking lander touched down on Mars, and since that time has been responsible for a succession of important new findings, beginning with the first description of single neurones with sharply restricted receptive fields in auditory space[5] and their arrangement into a map of auditory space[1].

The finding of the computational map of auditory space in the barn owl provoked a search for a comparable map in the brain of mammals, and 'hoops' sprang up in auditory neurophysiology laboratories from Oxford to Alabama to Monash. This search is still going on in the cat, despite a string of negative findings[6,7], and difficulties have been encountered in finding any representation of auditory space in the mammalian inferior colliculus. In contrast, numerous studies have found evidence of spatial representations of a variety of stimulus dimensions, all in register, within the mammalian superior colliculus. Sound space, visual space and even somatosensory space are all mapped with the same rough topography into the superior colliculus of various mammalian species; and maps of auditory space and of the direction of infrared sources are located within the equivalent structures of the owl[8] and rattlesnake[9] respectively.

Distortions occur in the course of the generation of maps which vary according to modality. Registration between maps can therefore be a problem and considerable interest has focused on this question. Gross misregistration can be corrected developmentally, as shown in elegant experiments by the Knudsens on young barn owls wearing prisms to displace their visual fields. In this case the map of auditory space shifts to realign itself appropriately with the visual map, whose coordinate frame is unchanged (relative to both the eyes and the head within which the eyes are immobile in owls).

Despite such plasticity, smaller local areas of misregistration still occur and are puzzling if considered in purely sensory terms. If, on the other hand, one considers the pool of motoneurones generating the orienting response from activation of some part of the map, precision or registration takes on a new meaning. This has been most clearly pointed out by McIlwain[10,11] who has formulated some rules for representations within the superior colliculus. A very precise orienting response may be driven by a rather diffuse activation of output neurones within the motor map since the precision depends upon coordinated activity in a very large pool of different motoneurones. McIlwain has shown how, as the final motor output is approached, the size of the 'point image' activated within the array by a stimulus increases to include a significant part of the whole map.

The point image can be thought of as the spatial distribution of neurones which are activated within a map by a punctate stimulus in the appropriate sensory space. The size of the point image in the map is determined both by the receptive-field size of individual neurones and by the degree to which receptive fields of neighbouring neurones overlap. A remarkable feature of a number of visual maps, first noticed by McIlwain, is that the mapping and receptive fields are related in such a way that the point image at a given map location has the same size as a receptive field at that location when the receptive field is projected onto the map. Accordingly, the very large receptive fields encountered in the deeper layers of the superior colliculus will be associated with large pools of output neurones, to which increasing attention is now being paid by recording from behaving monkeys. Thus, the large and apparently imprecise auditory receptive fields of the neurones in monkey superior colliculus[2] belie the precision with which the monkey can fixate an auditory 'target'. Precision within a motor map is more a matter of defining the boundaries of the motoneurone pool than of limiting the stimulus to a particular location, so one must take care to establish what the map is designed to represent.

Motor considerations can also help one to understand why the monkey's auditory map should move coordinately with the eyes, instead of having the head and ears as a fixed reference frame as one might expect of a map generated from head and ear cues. Apparently, what is being mapped onto the superior colliculus is the error between the current sound source direction and the current visual axis. Since the superior colliculus of the monkey has a motor map of saccadic eye movement vectors, the combination of the two maps would enable eye movements to be accurately programmed to fixate an invisible sound source. We can thus think of a map in 'motor-error space'.

A requirement for the motor-error schema is that a map has available a neural representation of current eye position. Such a representation also forms an important part of most successful models

of saccade-generation, the most notable of which (Robinson's bang-bang model) uses the degree of mismatch between a current-eye-position signal and an intended-eye-position signal to provide the drive for saccadic burst generators[12]. Just where the eye-position signals originate and how they are integrated with the map of auditory space remain difficult questions for the future, particularly in view of the current lack of information about how the auditory space map is generated in the monkey's midbrain. Future work on the midbrain maps therefore promises to illuminate a variety of important issues concerning the sensory–motor interface. □

Zoology

Back from the brink of extinction

from Jared M. Diamond

A RECURRING nightmare for conservation biologists is the discovery that the few surviving individuals of an endangered species are all of the same sex. In 1976 this nightmare came close to reality for the New Zealand Wildlife Service, with the discovery that of seven remaining Chatham Island Black Robins only two were females. This precipitated a drastic rescue programme, involving capture of the entire robin population, its transfer to another island and the fostering of eggs in the nests of two other species of song bird. As a result, for the first time in nearly a century, robins now occupy two islands[1]. The significance of the rescue programme, however, goes far beyond the fate of one obscure species of bird because without such sophisticated management techniques a growing number of species would be doomed and yet the techniques arouse passionate opposition.

Why was the Black Robin (*Petroica traversi*) on the verge of extinction in 1976? By the 1870s the cats, rats and forest-clearing activities of European settlers had eliminated the robin from the larger of the Chatham Islands, 800 km east of New Zealand, restricting it to Mangere and Little Mangere. After cats were introduced to Mangere in the 1890s they proceeded to destroy its robins and 11 other bird species, leaving all of the world's Black Robins in 4 hectares of scrub on the windswept top of Little Mangere. By 1973 there were 17 adults and 1 juvenile[2,3].

On Little Mangere the robins' long-term prospects of survival seemed poor. Apart from the risks intrinsic in the island's tiny area, it was riddled with the nesting burrows of Sooty Shearwaters, its forest was dying and few young robins were surviving. After considering the options, the New Zealand Wildlife Service decided to plant 100,000 tree cuttings on Mangere Island itself (where the cats had died out), intending to transfer the robins there when the trees had become tall enough to provide suitable habitat. Meanwhile it began transfer experiments and detailed field studies with the Black Robin's closest relative, the New Zealand Robin (*Petroica australis*)[3].

Unfortunately, the continued deterioration of Little Mangere's patch of scrub, and the poor breeding success of robins there, made it impossible to wait. When the 1976 census revealed only two pairs and three bachelor males, making the Black Robin the world's rarest accurately censused bird, the Wildlife Service decided on a drastic risky measure: the immediate transfer of robins to the 4.2 hectares of existing scrub on Mangere.

Rough seas, bad weather and an almost fatal boat accident aborted the first two attempts[4]. But between 17 and 21 September 1976 both pairs and one bachelor were caught and transferred and at the end of the breeding season, in March 1977, the two remaining males joined them on Mangere[5] so that the whole population of the Black Robin was on the one island.

Although the birds immediately began to breed on Mangere, recovery of the Black Robin population was slow because only two eggs are laid, and at best only one of those is likely to yield a fledged young. However, like many bird species, Black Robins will lay a second or even a third clutch if the previous clutch fails. So, in 1980 the first clutches of the two surviving pairs were transferred to nearby nests of another small insectivorous bird species, the Chatham Island Warbler. The robins relaid, and four robin chicks were fledged that year — three of them by warblers. But the warblers were incapable of caring for the growing robin chicks for more than ten days, after which they had to be fostered back to adult robins. So, in 1981 the first clutches were transported to nearby South East Island for foster-rearing by the Tomtit (*Petroica macrocephala*). These proved ideal foster parents and raised three of the five robin chicks produced that year[1].

To reduce the risk of inbreeding or of extinction by a local disaster on Mangere, where the robin habitat is at the base of an unstable cliff, two pairs of adult robins were transferred to South East Island in 1983. Despite unusually bad weather leading to the deaths of four robins in 1982 and 1983, the species entered the 1983–84 breeding season with three breeding pairs.

These interventions obviously involved big risks, both to the Black Robin and to the New Zealand Wildlife Service itself. Even before the near-fatal boat accident in 1976, the Service was aware that public opinion would tolerate the loss of a ranger during the transfers, but not of either of the two surviving female robins[2]. The courage and experience required to move an entire population of an endangered species grew out of need. Faced with destructive introduced mammals on the New Zealand mainland, inadequate budgets and the responsibility for an unusually high proportion of endangered or vulnerable endemic species, the New Zealand Wildlife Service has developed management techniques based on detailed studies of the ecology and sociobiology of endangered species. Foremost among them has been the introduction of threatened taxa to offshore islands from which introduced mammals are absent or have been eradicated. Such taxa as the South Island Saddleback, Buff Weka and Little Spotted Kiwi would be extinct today were it not for such introductions.

Nevertheless, in New Zealand as elsewhere, the philosophy of drastic intervention to save endangered species elicits opposition as well as support, even amon biologists. The debate over whether t transfer some Black Robins from Mangere to South East Island is not unlike the debate in the United States over the captive breeding programme for the California Condor. Sometimes opposition is based on doubts about the particular form of intervention proposed, the risk of individuals being killed and the possibility that a programme will draw off too much money from other conservation programmes. Partly, too, the opposition stems from revulsion at intense artificial manipulation of wild populations, even in the hope of saving them: should not the last condors be allowed to die in dignity in the wild, rather than as captives in a zoo? Breeding of Black Robins will have to be managed for a while to avoid effects of inbreeding, and perhaps to avoid imprinting on foster-parents. Does this not blur the distinction between maintenance in the wild and in a zoo, and thereby virtually convert Mangere and South East Island into outdoor zoos?

Many people, however, feel that managed robins are better than no robins and that humans should devote ingenuity and massive intervention to saving species as well as to exterminating them. Without intervention in 1976 the Black Robin would soon have met the fate of the Dusky Seaside Sparrow. For this doomed bird of Florida marshes, the conservationists' nightmare has come true: the few surviving individuals are all males. □

Protein crystallography

Fifty years of pepsin crystals

from Guy Dodson and Cyrus Chothia

In the middle of April 1934, J.D. Bernal and Dorothy Crowfoot (now Hodgkin) obtained the first successful X-ray photographs of a globular protein. They were obtained in Cambridge from crystals of pepsin grown by John Philpot in Uppsala. The photographs, discussed in a letter to *Nature* (**133**, 794; 1934) published half a century ago, almost to the day, were the start of one of the great achievements of modern biology.

On 13 April 1984 a meeting was held in Cambridge to commemorate the fiftieth anniversary of the experiment. Lectures were given by Dorothy Hodgkin, Max Perutz and Aaron Klug, all of whom worked at different times in Bernal's laboratory. The occasion brought together all those still living who were directly involved in the pepsin experiment; sadly, Peter Wooster, a long-established figure in Bernal's laboratory and remembered warmly by many, died on the night preceding the meeting. Several crystallographers who had contributed to the field, notably Arthur Wilson (intensity statistics) and Henry Lipson (Fourier calculation methods), were also present.

Part of the meeting was devoted to a recreation of the events that led to the pepsin crystal's coming to Bernal's laboratory at Cambridge and to the crystallographic examination of pepsin and other protein crystals (including viruses) that subsequently took place. The historical accounts were filled out, sometimes straightened out, particularly by John Philpot on the background of the crystallization of pepsin (in explaining why he went to Uppsala to grow the crystals he distinguished nicely between his real reason for going there — a young lady — and his excuse — to work on the ultracentrifuge) and by Bill Pirie on early virus experiments. The history of pepsin was completed by a comment from Tom Blundell on the structure of the pepsin molecule inferred from homologous enzymes.

The impressions that emerged of Bernal's laboratory were of great activity and many abilities, and of Bernal's omnivorous scientific interests. The laboratory already had a famous reputation, particularly for the work on sterols, and it was this, or Dorothy Crowfoot's reputation, that apparently prompted Glen Millikan, a peripatetic scientist, to bring John Philpot's crystals to Cambridge.

When the crystals arrived, Bernal immediately examined them in a polarizing microscope (Dorothy Crowfoot was away with what proved to be an incipient rheumatic attack). He found them to be beautifully formed, showing sharp birefringence while in the tube they had been grown in. The crystals failed to diffract after removal from the test tube and drying but, crucially, Bernal noticed that their birefringence had also disappeared. Thus he realized the need to keep crystals wet. Bernal's solution was to put the crystals in capillaries (made possible because of Helen Megaw's studies on ice crystals). The subsequent investigation of the crystal's diffraction characteristics, cell dimensions and space group was carried out by Bernal and Dorothy Crowfoot. It led to their recognition "that the arrangement of atoms inside the protein molecule is of a perfectly definite kind" and to remarkably accurate ideas about the molecules' molecular weight and shape.

The descriptions of the subsequent research into protein crystals included the details of how the studies on insulin, haemoglobin and the viruses began. The immense difficulties in solving these structures were clearly appreciated at the time and the early investigations were devoted to measuring X-ray intensities, to calculating the Patterson function (also celebrating its fiftieth anniversary this year) and to characterizing new protein crystals. The influence of Bernal and Bragg was clearly crucial. A typical contribution was Bernal's letter to Dorothy Crowfoot suggesting that the isomorphous replacement of Zn by Cd in the rhombohedral insulin crystal could give phase information. Bragg's role, more concentrated at first on haemoglobin and later on myoglobin, was quieter but his steady sympathy, persistence and deep crystallographic insight helped the early research through disappointing years. Perutz recalled Bragg's grasp of crystallographic principles and illustrated it by the studies on how the shrinkage of protein crystal cells could be used to define centric phases.

In his review of virus research and the structure of water, both deep interests of Bernal, Klug emphasized the importance of flexible thinking and how Bernal's aphorism, 'crystallographers must learn not to be crystallographers', applied over and over again. This was as true in Pauling's production of the α-helix structure and in Bernal's approach to the water problem as it is now in the study of the behaviour of protein structure which is increasingly found to link well defined domains to flexible and variable segments. Thus, the linking of order and disorder to achieve assembly and function (RNA binding) in the tobacco mosaic virus is revealed by crystallographic analysis. A report by Steven Harrison (Harvard University) of the 2.8 Å resolution crystal structure of tomato bushy stunt virus nicely completed studies begun by Bernal and Fankuchen. This virus also demonstrates beautifully the order–disorder phenomenon, which Harrison showed is related to the packing and assembly of the virus subunits.

There are many conclusions from a day like this. First, there are the remarkably happy collaborative traditions in protein crystallography, established from the earliest days, that make it such fun to work in the field. Second, the techniques, essentially physics, have put the description of protein and biomolecular structure into the hands of crystallographers. Finally, the importance of crystals and other ordered systems as a route to the description of biochemical and biological structure remains paramount. Bernal saw these descriptions as the first stage — their analysis should lead to the principles which govern the assembly and integration of molecules into higher organizations. Already, as Richard Henderson emphasized, crystals of very large molecular assemblies such as the nucleosome have been solved. Thus, as long as there are crystals, the future of the field is assured and more than justifies the great excitement produced by those first X-ray photographs of pepsin. □

Crystallography

Defects in reduced oxides

from C.J. Humphreys

CRYSTALS are like people: it is the defects in them which tend to make them interesting. In recent years, solid-state physicists and chemists have become increasingly aware that real crystals are usually not perfectly periodic arrays of atoms. Instead they contain a variety of isolated defects, which are important because they can strongly influence the physical and chemical properties of the crystals. An article on page 319 of this issue, by Bursill and Smith, reports the use of high-resolution electron microscopy to provide new information on the isolated defects which form when oxide crystals are reduced. This is the latest development in understanding reduced oxides, which have long puzzled chemists and physicists.

The basic question is the following: when oxide crystals are reduced (for example, $MoO_3 \rightarrow MoO_{3-x}$), are the resulting oxygen vacancies in the structure distributed homogeneously or are there isolated extended defects, and if so how do they form? Until 1950 it was believed that the oxygen vacancies were distributed homogeneously. Then A. Magnéli (*Ark. Kemi* **1**, 513; 1950) observed extra diffraction spots in X-ray diffraction patterns from reduced oxides which he correctly attributed to an ordered array of defects called crystallographic shear planes (CSPs). Five years later A. D. Wadsley postulated the existence of isolated CSPs (*Rev. pure appl. Chem.* **5**, 165; 1955). But the then available techniques of X-ray and neutron diffraction gave diffraction patterns which yielded atomic positions statistically averaged over a relatively large diffracting volume (typically 1 mm^3) of the crystal and so were incapable of detecting individual crystal defects. It took another fourteen years before Wadsley's predictions were confirmed by the observation of isolated CSPs by electron microscopy (Bursill, L.A. & Hyde, B.G. *Phil. Mag.* **20**, 657; 1969).

We can think of CSP formation as follows. If it is energetically favourable for them to do so, oxygen vacancies will cluster together on a crystal plane rather than exist as isolated vacancies. The crystal on each side of this cluster of vacancies will then collapse into the missing layer of oxygen atoms and also shear sideways to reform chemical bonds. The defect so formed is a CSP. In MoO_3 the local chemical composition at a CSP is MoO_2. Hence a reduced crystal of overall composition MoO_{3-x} can be thought of as a matrix of MoO_3 plus the appropriate number of CSPs of composition MoO_2. We thus have a beautifully simple concept of how oxygen vacancies are accommodated in reduced oxides. If there are a number of CSPs in a crystal they will form an ordered array at a sufficiently high temperature, as Magnéli originally observed.

The picture I have just given is a simplified one. In particular, for a very small degree of reduction (corresponding to $x<0.005$) CSPs are not usually observed. Are the oxygen vacancies at these low concentrations uniformly distributed or are they concentrated into isolated small defects, and how do the CSPs form and grow? These are the questions that Bursill and Smith can address in their paper because of the availability of the latest generation of very high-resolution electron microscopes, with a resolution of less than 0.2 nm. They show, for the first time, that there are small localized defects which precede the CSPs and that these defects may be characterized through careful analysis of very high-resolution electron micrographs. Thus we gain new insight into the earliest stages of structural changes that accompany reduction. This work is not only important for chemists and physicists studying oxides but also illustrates the power of high-resolution electron microscopy for studying, at the atomic level, the structure of defects in a wide range of materials. □

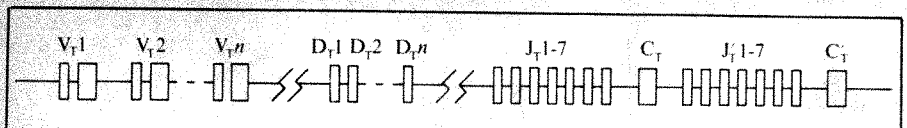
Immunology

More on the T-cell receptor

from Philippa Marrack



NOT surprisingly, one of the main subjects of interest at a recent symposium* on 'Regulation of the immune system' was the receptor on T cells which allows them to respond clonally to antigen in association with products of the major histocompatibility complex (MHC). A year or two ago, when the molecules responsible for this feat were identified on the surfaces of T-cell clones, using clone-specific antibodies, they were shown to be disulphide-linked proteins made up of two different chains each of molecular weight 40,000–50,000 and containing variable and constant peptides. The T-cell receptor was therefore recognized to be strikingly similar in overall design to immunoglobulins. Recent papers in *Nature* (**308**, 145 & 149) reported the isolation of cDNA clones which probably encode one of the two polypeptide chains.

Since nearly all the protagonists involved in these discoveries were at the meeting, immunologists were given an opportunity to be brought up to date on all aspects of this work. Steven Hedrick (University of California, San Diego) and Tak Mak (Ontario Cancer Center) reviewed the data on the cDNA clones. The mRNAs from these clones are T-cell specific, come from genes which rearrange between the germ line and mature T cell, and are similar but not identical to immunoglobulins in nucleotide sequence. Moreover, the proteins they encode are very immunoglobulin-like in sequence and, in particular, include cysteines which could mark the domain-like structures so characteristic of this type of molecule. Hedrick also pointed out that the cysteine near the carboxy-terminal end of the protein is in a position analogous to the cysteine on immunoglobulin light chains. Since the latter is involved in bridging light chains to heavy chains in most immunoglobulins, the former may have a similar function in the T-cell receptor, being used to bridge the two chains of the heterodimer.

Mark Davis and Nicholas Gascoigne (Stanford University) described the structure of mouse genomic clones encoding these sequences; their data are published on page 322 of this issue. Again there are striking similarities with immunoglobulin, since several segments of DNA, which occupy separate loci in the germ-line genome but are brought together by rearrangement in T cells, contribute to T-cell receptor cDNA (see the figure). One segment contains a cluster of variable-region (V_T) genes, mapping an undetermined distance from a proposed segment containing several diversity-region (D_T) genes (DNA encoding this segment has not yet been found). A third segment contains a cluster of seven joining-region (J_T) genes and a constant-region (C_T) gene. The last contains four exons, of which three were expected: the exons for the constant-region immunoglobulin-like domain, which is extracellular, a transmembrane sequence, and a cytoplasmic domain. But the fourth, encoding four to six amino acids between the extracellular domain and the transmembrane sequence, came as a surprise. This extra domain has some sequence homology with the hinge region of immunoglobulins, the part thought to confer flexibility on antibodies. A lack of prolines in the hinge region of the T-cell receptor suggests it might not be quite so flexible. The cysteine equivalent to that thought to be involved in interchain disulphide bonds in antibody molecules is found in this exon.

Davis and his co-workers have found

*The Ortho-UCLA symposium on 'Regulation of the immune system' was held in Park City, Utah, 18–25 March.

Arrangement of the genes for the separate domains of one chain, probably the β chain, of the T-cell receptor. Bars represent genes. The D_T region is provisional.

two very similar C_T genes, close together on the same genomic clone. Each seems to have its own cluster of J_T genes; there is evidence that each V_T gene can feed off either cluster of J_Ts. If so, this arrangement would be similar to that of the immunoglobulin light chain, λ. These results were confirmed by Mitch Kronenberg (Caltech). The human gene structure seems to be similar since Mak has also found two closely arranged constant-region genes. In mouse the genes map to the proximal region of chromosome 6 (Davis and Kronenberg).

There is some evidence that the T-cell repertoire, at least reflected by use of these genes, is limited. For example, there is no evidence for somatic variation, although so far only a limited number of sequences have been looked at. Davis mentioned that the V_T-region sequence found in a T-cell hybridoma specific for pigeon cytochrome *c* in association with $I\text{-}A^k$ is identical to its germ-line counterpart. Perhaps less surprisingly, Hedrick showed that three independent T-cell hybridomas with the same specificity for cytochrome *c* and I-A seem to use the same V_T region, at least for this chain, since all show the same size rearrangement of the gene.

Which of the two polypeptides, unimaginatively called α and β, of the T-cell receptor are coded for by the genes detected by the cDNA probes? Ellis Reinherz (Harvard University) and his collaborators have shown that the amino-terminal sequence of the variable region described by Mak is almost identical to the amino-terminal amino acid sequence they have obtained for the β chain.

With every indication that the arrangement and rearrangements of T-cell receptor genes have been, or soon will be, worked out, interest turned to their expression. All investigators agreed that the genes are rearranged and transcribed only in T cells although not, perhaps, in suppressor T cells. The high level of mRNA produced from the genes in thymocytes is of particular interest because the thymus is the organ in which the ability of T cells to recognize antigen in the context of self-MHC is thought to be selected. Presumably this selection depends on the expression of receptor proteins on thymocyte surfaces. Some doubt that high levels of mRNA necessarily result in high levels of cell-surface receptor was raised by John Kappler (National Jewish Hospital, Denver), who described a monoclonal antibody which binds to the receptors on about 20 per cent of peripheral T cells in most mouse strains. Each of these cells has $3\text{–}4 \times 10^4$ receptors on its surface whereas the number of receptors on immature thymocytes ranges from zero to about the same as on the peripheral T cells. Those without any receptors may not yet have generated the ability to synthesize mRNA for both chains of the receptor, or may have lost this ability because of mutation or aberrant rearrangement.

Since cytotoxic T cells usually recognize antigen in association with class I products of the MHC, whereas helper T cells usually recognize antigen in association with class II MHC products, some difference between the receptors on the two types of cells has long been expected. Although no differences were identified with the cDNA probes or with Kappler's antibody, a first inkling of their existence was suggested by J.P. Allison (University of Texas Cancer Center, Smithville) who showed that antibodies produced in rabbits against the purified receptor from a mouse T-cell leukaemia preferentially react with a subset of receptors on L3T4-bearing mouse T cells, the cells thought to be mainly class II-restricted helper T cells.

Some years ago Jerne suggested that an immunological network controls the specificities of lymphocytes in any given animal since each new variable-region sequence is, in a sense, an antigen new to the animal and so potentially recognizable by other variable regions — of antibodies or on T cells. Hence the suggestion that there might be a subset of T cells which recognizes the T-cell receptor on other T cells and does so by means of a receptor that bears some resemblance in structure to the MHC antigens recognized by the T-cell receptor. Sim and Augustin (Denver) supported that suggestion with evidence that a T-cell hybridoma, prepared from mice immunized with an anti-I-A antibody, responds to that antibody in the absence of any other stimulus, and that the antibody can precipitate from the hybridoma a structure similar to other antigen-specific MHC-restricted T-cell receptors.

The idea that T cells might bind anti-MHC antibodies, in particular those directed against class II-like molecules, not because they bear products of the MHC itself but because they bear receptors which resemble MHC products (internal images), was used at several points in the meeting to explain the still mysterious existence of antigens on T cells which seem to map genetically in the *I* region, especially the *I–J* region, of the MHC. But why, then, are *I*-region-related messages not expressed in T cells (Kronenberg)? Colleen Hayes (University of Wisconsin) and her colleagues have recently published data which suggest that the determinants found on T cells known as I–J are controlled in the mouse by genetic loci mapping both in the MHC, on chromosome 17 and on chromosome 4, suggesting some sort of complementation (*Science* **223**, 559; 1984). Internal-image devotees now theorize that I–J, and other structures on T cells which react with anti-MHC antibodies, may be T-cell receptors which mimic the MHC but which are encoded by genes not mapping at this locus. This may be true for MHC-restricted helper and cytotoxic T cells, as exemplified by the Sim and Augustin experiment, and for free-antigen-binding suppressor T cells, which apparently have a different type of receptor. □

NOTES

M. PASTEUR read to the Academy of Sciences on Monday an account of his experiments on rabies. He maintains that he has twenty dogs which he has rendered insusceptible to the disease, and which, with twenty ordinary dogs, he is prepared to have bitten by a number of dogs in a rabid state. A Commission has been appointed by the French Government to test M. Pasteur's conclusions, the immense importance of which, if established, must be evident to every one. Eminent physiologists maintain, however, that M. Pasteur is far from having proved his position, and that it would be rash to give any positive opinion upon the subject until the experiment which he suggests has been made. We await the full report of M. Pasteur's paper before saying more upon it.

From *Nature* **30**, 22 & 29 May 1884.

A REMARKABLY BRILLIANT METEOR

TO-NIGHT, about 10.45 p.m., I was "stepping westward," about half a mile east of my house. Suddenly the ground before me was lighted up with moontide splendour by a luminary that was above me and behind me. Looking back I saw a meteor a good deal east of the Grat Bear, and nearly as high in the sky. It was about as big as Venus, and of the same hue. It was speeding from north to south with a slight descent. Its course very soon came to an end. It left behind it a streak of duller lustre: this phosphorus-like trail vanished almost at once. The career of this meteor while that body was visible here, lasted little, if at all, longer than a minute, but its light was remarkably brilliant.

DARK TRANSIT OF SATELLITE

ON May 18, at 8 h., on observing Jupiter with my 10-inch reflector, p. 252, I saw three very dark spots. These I took to be the shadows of satellites, and on reference found that the shadows of Satellites I. and II. were really upon the planet; also Satellite I. itself. I believe the very dark appearance of the satellite on this occasion to have been somewhat exceptional; for through I have observed a considerable number of its transits, I never saw it nearly so dark before.

Molecular biology

DNA bending and kinking

from Jonathan Widom

To pack double-stranded DNA into the protein shell of viruses such as phage λ, or to wrap it around the protein cores of the nucleosomes that characterize the chromatin of higher organisms, requires the DNA to be tightly bent or kinked at many sites. In the simplest case, DNA may have only a passive role in its packaging. In other cases, sequences within the DNA may specify the bending or kinking, or bends or kinks could be induced by the binding of proteins. Experiments described in a recent issue of *Nature*[1] and on page 327 of this issue[2] provide evidence of both of the active mechanisms of bending or kinking.

To understand the degree of bending required of DNA packaged in viruses and in chromatin, one must have a quantitative measure of the stiffness of isolated DNA. This has been obtained by hydrodynamic methods[3], and extended to tight bending (~ 240 base pair circles) by Shore *et al.* using an enzymatic ring-closure method[4]. The persistence length of random-sequence DNA is found to be ~500 Å, or ~150 base pairs (bp)[3]. DNA must be tightly bent or kinked when packaged in phage λ because the hollow protein capsid has a diameter of only 600 Å (ref.5). On a nucleosome, DNA is bent through 360° in the space of ~ 80 bp (ref.6), only half of the persistence length of DNA in solution.

Adding to the interest in what determines bends or kinks in DNA is the possibility that altered DNA conformation may serve as an important signal in the sequence-specific binding of proteins. Thus in 1975, Crick and Klug[7] pointed out that several base pairs at a kink may be particularly accessible to proteins and, on the basis of model-building studies, several groups have proposed non-B-form conformations for DNA bound to proteins (for example, refs 8 and 9). Although the structures of three sequence-specific DNA-binding proteins (cro[10], cI[11], CAP[9]) have been solved by X-ray diffraction, the proteins were not bound to DNA, so only by model-building could their mode of binding be tentatively predicted. That is the reason for the special importance of the two new papers[1,2] which clearly show striking departures from linear B-DNA in both isolated DNA and in DNA–protein complexes.

Wu and Crothers report an elegant experiment which indicates that a particular DNA sequence may cause the DNA molecule to bend[1]. The DNA they have worked with is a restriction fragment from the kinetoplast of a trypanosome. The kinetoplast contains a large number of highly-interlocked, very small (~ 800 bp) DNA circles of unknown function. Marini *et al.* had reported anomalous electrophoretic and hydrodynamic behaviour for one particular restriction fragment, which led them to postulate that the fragment may be bent[12]. To test that suggestion, Wu and Crothers devised an elegant technique (circular permutation) of generating from the anomalous restriction fragment a series of variants differing only in the position of the suggested bending locus relative to the ends of the fragment. When these essentially identical restriction fragments were run on non-denaturing acrylamide gels, a striking range of mobilities was observed, consistent with the proposal that the original fragment was bent at a specific site. Theories of gel electrophoresis[13] predict (for a given molecular mass) a dependence of mobility on h^2, the mean-squared end-to-end distance of the molecule. If a sequence at the centre of a restriction fragment causes that molecule to bend, it will have a reduced h^2 and hence should migrate more slowly in gels. If that same restriction fragment is circularly permuted to place the site of bending at the very end of the molecule, h^2 should be restored to its expected value, so the fragment should migrate more rapidly. By extrapolating their mobility data, Wu and Crothers are able to pinpoint the DNA sequence that causes the bend. In the restriction fragment from the kinetoplast minicircle (K-DNA), they find a very striking sequence at the centre of the bend: the sequence $C(A)_{5\text{-}6}T$ is repeated four times, separated by three or four other bases so that the sequences are spaced ~ 10 bp apart, in phase with the twist of the DNA helix.

Theories of gel electrophoresis are not sufficiently developed to allow one to be certain of the reason for the anomalous mobility of K-DNA. An alternative explanation, not considered by Wu and Crothers, is that rather than conferring a permanent bend with definite geometry, the sequence $C(A)_{5\text{-}6}T$ could simply confer increased flexibility, and that increased flexibility results in slower migration in gels. Hogan *et al.*[14] recently reported enhanced flexibility for the sequence poly(dA)·poly(dT), and Charney and colleagues (personal communication) have found a greatly enhanced flexibility for the sequence poly(dA-dT)·poly(dA-dT).

Although it is therefore reasonable to expect that the sequence found by Wu and Crothers will have an increased flexibility, two lines of reasoning suggest that increased flexibility alone cannot account for their results. First, Charney and colleagues find that, while having substantially enhanced flexibility, poly(dA-dT)·poly(dA-dT) does not behave anomalously on polyacrylamide gels. Second, increased flexibility would not account for the striking 5 and 10 bp periodicities of the K-DNA bend locus. Wu and Crothers suggest that runs of $dA_{5\text{-}6}$ may have an altered helical conformation, such as the heteronomous DNA (H-form) postulated by Arnott and colleagues[15]. When a B-form to H-form junction is created, it is likely to involve a bend[15]. The two strands of H-form DNA are non-equivalent, so there will be a directionality to an H–B junction (with respect to the polar phosphate–sugar backbone), producing bends of opposite sense at H→B and B→H junctions. Because the runs of A are 5–6 bp long — half of the helical periodicity of DNA — bends of opposite sense at the entrance and exit of $A_{5\text{-}6}$ blocks will point in the same direction to produce a planar bend rather than a zigzag. There are four of these units in the K-DNA bending locus; because the units themselves repeat every ~ 10 bp, planar bends from individual units add in-phase to produce a large net planar bend. If these sequences promoted bending merely by virtue of their flexibility, the 5 bp periodicity, especially, would be unnecessary and not expected.

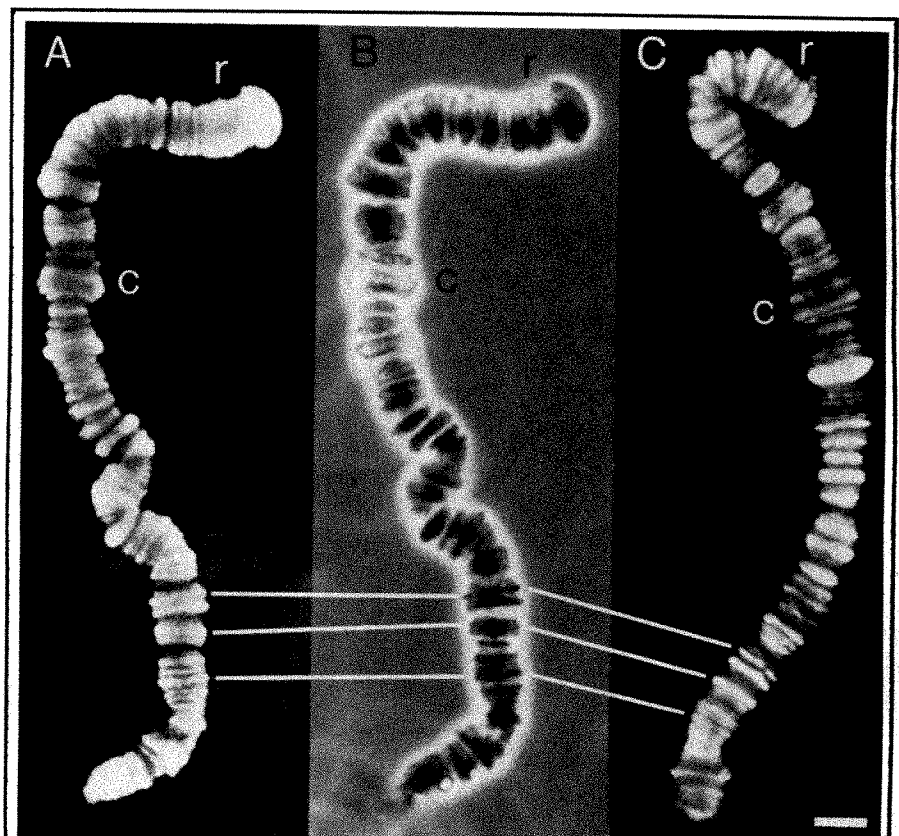
In a parallel series of experiments, Wu and Crothers showed that the mobility of circularly permuted variants of a restriction fragment from the *lac* control region of *Escherichia coli* does not vary with circular permutation, even when lac repressor tetramers were bound at the operator site. When dimers of CAP protein (which are much smaller than lac repressor tetramers) were added, however, there was a marked dependence of the mobility on the degree of circular permutation. Previous experiments have shown that both CAP and lac repressor remain correctly bound to the DNA during electrophoresis (see refs 1,16). Wu and Crothers conclude that the *lac* DNA fragment is itself unbent but that it bends in response to the binding of CAP protein. The same conclusion based on related experiments had previously been reached by Kolb *et al.*, who obtained fragments with the CAP-binding site at different locations relative to the fragment ends from many different control regions of *E. coli*[16]. By extrapolating their mobility data, Wu and Crothers map the CAP-induced bend to a point within the CAP-binding site that is several bases towards the promoter from the binding site centre of symmetry. This raises the possibility that CAP acts to promote transcription by stabilizing an altered DNA conformation which may be favoured by RNA polymerase.

Turning to the paper of Frederick *et al.*, on page 327, one is presented with the striking results of the first X-ray diffraction structure of a complex of protein and DNA[2]; the results bear directly on the issues of sequence-specific recognition and DNA packaging. Frederick *et al.* have studied the complex of the restriction enzyme *Eco*RI with DNA, formed in the absence of Mg^{2+} so that the enzyme did not hydrolyse the DNA. The DNA has the

sequence: TCGCGAATTCGCG
GCGCTTAAGCGCT

That sequence contains the recognition sequence for *Eco*RI, GAATTC, and is closely related to the dodecamer studied by Dickerson and colleagues[17]. Frederick *et al.* find that the protein-bound DNA has several unusual features, including three kinks. One kink (the 'neo-1' kink) is in the centre of the DNA molecule, on the dyad symmetry axis, and represents a torsional dislocation between two segments of B-form DNA. One can think of this kink as being generated in two steps: first, the DNA is unwound by 25° between the base pairs to either side of the kink, then the DNA is bent 12° into the minor groove. This is the mechanism of kinking postulated by Crick and Klug[7] in their kinked-helix model, but the present neo-1 kink differs from the Crick–Klug kink by restricting itself to a modest 12° bend, rather than taking advantage of the full 100° bend that model-building suggests is available. In the complex with *Eco*RI, the neo-1 kink is required to widen the major groove, facilitating access to the bases and allowing an extensive complementary interface with the protein dimer.

The other two kinks ('neo-2 kinks') differ from the neo-1 kink, but are identical to each other because they occupy equivalent positions about the complex's dyad axis. The neo-2 kinks separate the terminal (T)CGC blocks from the central GAA blocks and are produced in a different way from the neo-1 kink. They lack noticeable unwinding; a base-roll[17] into the minor groove produces a bend of 23°. While the central GAA blocks appear to be B-like, the terminal (T)CGC blocks appear to be A-like. Frederick *et al.* suggest that the neo-2 kink may arise from the joining of these two different DNA conformational blocks. It should be noted that in a previous model-building study, Selsing *et al.*[18] found that they could not build a stereochemically acceptable A–B junction of the sort proposed here. Selsing *et al.* found it necessary to have at least one intervening base pair separating orthodox A-and B-form regions. A better understanding of the neo-2 kink must await determination of the atomic positions of the base pairs involved.



A final striking feature of the *Eco*RI–DNA complex concerns the effects of DNA sequences flanking the enzyme's recognition sequence, GAATTC. Different flanking sequences are known to influence the hydrolysis rate by an order of magnitude[19]. Surprisingly, therefore, Frederick *et al.* see no contacts between *Eco*RI and DNA bases outside the recognition sequence; only the backbone appears to be contacted. They conclude that the flanking sequences may affect enzyme activity by changing the conformational free energy of the neo-2 kink or of the GCC terminal blocks. An alternative possibility is that different flanking sequences may give rise to different local DNA backbone conformations, for which the enzyme may have different affinities.

One must be aware that *Eco*RI is a hydrolytic enzyme, whose function is to cut the DNA chain between the bases G and A in the sequence GAATTC. The site of cleavage is only 1 bp away from the neo-2 kink and 2 bp away from the neo-1 kink. Presumably the enzyme acts by stabilizing a transition state in which the G-A backbone has an increased lability to hydrolysis. It is feasible that either the neo-2 kink or the neo-1 kink may destabilize the G-A backbone bond, and indeed this may turn out to be the *raison d'être* of the neo-2 kink. This does not detract from the important conclusion that for both CAP and *Eco*RI, and probably many other proteins, dramatically altered DNA structures will be important features in the DNA–protein complexes.

Taken together, the new studies of K-DNA and of CAP–DNA and *Eco*RI–DNA complexes show that the structure and function of a DNA molecule can be affected in important and unexpected ways both by the DNA sequence itself and by the interaction of specific proteins with the DNA. These results suggest that altered DNA conformations are likely to play an important part in DNA packaging and in the sequence-specific recognition of DNA by proteins. □

Z-DNA: the acid test

Acid treatment of polytene chromosomes of *Drosophila* before their exposure to an antibody against Z-DNA resulted in these striking immunofluorescent micrographs. A phase-contrast image of an isolated chromosome (B) allows its bands to be clearly identified and makes obvious that Z-DNA is associated with them, both in an acid-treated isolated chromosome (A) and in a 'squash preparation' of a chromosome prepared after acid fixation of the salivary gland (C). In less acid conditions, far less Z-DNA is apparent and it is confined to the periphery of the bands; acid treatment, by stripping proteins from the DNA and by protonating its bases, may both expose masked Z-DNA and induce the transition of B-DNA to Z-DNA. The lines connect bands, 'c' denotes centromere, 'r' the right-hand end of the chromosomes and the bar represents 10 μm. From Robert-Nicoud, M., *et al. EMBO J.* 3, 721 (1984).

Mathematics

Beyond reasonable doubt?

from Ian Stewart

WHEREAS the mathematical discipline of Number Theory deals with properties of whole numbers, that of Analysis is concerned with the continuous properties of real and complex numbers. Despite this difference, Bernhard Riemann, in 1859, discovered profound connections between the two, leading to what is now known as Analytic Number Theory. Riemann developed a theory of the zeta function, defined for real $s > 1$ by

$$\zeta(s) = 1^{-s} + 2^{-s} + 3^{-s} + \ldots$$

and for complex s by analytical continuation, and showed how it could be used to study the distribution of prime numbers (*Monatsber. Akad. Berlin*, 671; 1859). In particular, the number of primes in a given interval could be estimated provided enough was known about the zeros of the zeta function: values s such that $\zeta(s) = 0$. There are some relatively obvious zeros at $s = -2, -4, -6, \ldots$. Riemann conjectured that all the remaining zeros lie on the complex line $s = \frac{1}{2} + iy$ where y is real. This, the Riemann Hypothesis, if true, has extensive repercussions — not all within Number Theory. It remains an intriguing and important unsolved problem.

Computer calculations, based on various known features of the zeta function, have shown that Riemann's hypothesis holds good for the first 320 million zeros (Edwards, H.M. *Riemann's Zeta Function*, Academic, New York; 1974). This would appear to be strong evidence in favour of the hypothesis — but is it? An analogous question is illuminating. In 1885 T.J. Stieltjes came up with a different conjecture which would, if true, imply the Riemann Hypothesis (*C. r. hebd. Seanc. Acad. Sci., Paris* **101**, 368). It was proposed again by F. Mertens in 1897, after whom it is now named (*Sber. preuss. Akad. Wiss.* **106**, 761). It can be stated as follows. For any integer n, let $M(n)$ be the difference between the number of integers less than n that are products of an even number of distinct primes and the number that are products of an odd number of primes. The Mertens Conjecture is that $M(n) < \sqrt{n}$ for $n > 1$. For example when $\sqrt{n} = 16$ there are five numbers in the 'even' case (1,6,10,14,15) and six 'odd' (2,3,5,7,11,13), so $M(16) = 1$ which is certainly less than 4. The Mertens Conjecture has been verified by computer calculations for the first 10 billion values of n.

Despite the apparently overwhelming evidence in its favour, it has recently been discovered that the Mertens Conjecture is false. Andrew Odlyzko (Bell Laboratories) and Herman te Riele (Centre for Mathematics and Computer Science, Amsterdam) have shown in unpublished work, based upon fast computer techniques, that there exist infinitely many values of n for which the conjecture fails. The first 'bad' n is no larger than 10 to the power 10 to the power 70 (or thereabouts), an order of magnitude totally inaccessible to direct computation. It is possible that an explicit calculation of the actual 'bad' values would not be an improvement on the demonstration that they must exist.

The Riemann Hypothesis is unaffected by this result: it is still unsolved. Experts have long felt that to prove it by way of the Mertens Conjecture would be 'too easy', and their suspicions are now vindicated. Meanwhile, if the first 10 billion numbers are conspiring to mislead us about the Mertens Conjecture, what faith can we place on a mere 320 million in favour of the Riemann Hypothesis? □

Astronomy

IRAS circular 11

THE sources in this circular all have a firm detection at 60 μm, are at least 20° away from the galactic plane and have continua representative of 'warm' galaxies. Each search box has been inspected on SERC/ESO Schmidt survey plates or on National Geographic/Palomar Schmidt plates, and contains an obvious candidate, in most cases a galaxy. Selection of sources and the optical search were done by G.K. Miley and M.H.K. de Grijp, Sterrewacht Leiden, The Netherlands. Source names derived as before; see *Nature* **309**, 480; 1983. Position is given at equinox 1950.0. Measurements were made between epochs 1983.1 and 1983.9. In the table, a m denotes arc min.

Also now available, but not to be published in *Nature* is IRAS circular 10 which lists 179 sources selected from the IRAS minisurvey of an area of approximately 300 square degrees between 9 and 16 February 1983 (see Rowan-Robinson *et al. Astrophys. J. Lett.* **278**, L7; 1984). The sources satisfied the criteria of being more than 20° away from the galactic plane, reproducible on successive scans and with a signal-to-noise ratio of greater than 9:1 in at least one of the wavelength bands.

The IRAS fast-moving object search

J. K. Davies*, S. F. Green*, B. C. Stewart†, A. J. Meadows* & H. H. Aumann‡

The Infrared Astronomical Satellite (IRAS) has provided an all-sky survey at wavelengths between 12 and 100 μm. The satellite also detected fast-moving objects in the Solar System, including new comets and Earth-crossing asteroids, one of which may be an extinct cometary nucleus.

THE first satellite dedicated to astronomical observations at IR wavelengths, the US/Netherlands/UK Infrared Astronomical Satellite (IRAS), was launched on 26 January 1983. The IRAS mission was intended to provide a highly reliable all-sky survey in four wavelength bands centred on 12, 24, 60 and 100 μm (refs 1–4) (These are usually described as bands I, II, III, IV respectively.) The satellite was also able to detect and identify fast-moving objects within the Solar System. In this paper we review the search procedures applied to IRAS data, and the consequent discovery of several new comets and asteroids.

Search strategy

The IRAS survey objectives of high reliability and completeness were achieved by repeated detections in each wavelength band. The detector layout in the focal plane, when combined with overlapping and repeated scans, allowed the positions of sources to be confirmed on time scales of seconds, hours and weeks. This process of repeated confirmation also provides a means of detecting moving objects, as sources which do not repeat at the same celestial coordinates are rejected by the processing software at the ground station. (It should be emphasized that the confirmation process is based on positional agreement, and not flux comparisons between detections; so fixed, but variable, sources are not rejected.)

The sources which were not confirmed during the survey may be divided into three groups.

(1) Seconds confirmation failures. These include objects near to the spacecraft, such as Earth satellites, space debris and material evolved from IRAS; but most seconds confirmation failures are attributable to radiation hits on the detectors.

(2) Hours confirmation failures. These include Solar System objects moving across the sky at more than ~1 arc min h^{-1} (for example, some comets, some main-belt asteroids and most Earth-crossing asteroids).

(3) Weeks confirmation failures. These include slow-moving Solar System objects (such as distant asteroids, comets and planets).

Note that large numbers of detections in band II only, appeared to pass the seconds confirmation test. Examination of the raw data for these detections showed no evidence for the presence of a point source. These apparently spurious point sources should probably be attributed to fluctuations in the diffuse IR background. Chance pairings of these spurious sources were output as possible asteroid candidates. They represented by far the largest group of sources processed by the moving-object software and seriously hindered the search for faint asteroids.

Data from IRAS were transmitted to the Preliminary Analysis Facility (PAF) at the Rutherford Appleton Laboratory in the UK, where examination was confined to seconds and hours confirmation. The raw data were then transmitted to the Science Data Analysis System (SDAS) at the Jet Propulsion Laboratory, California for comprehensive analysis and production of the final data products. Slow-moving Solar System objects which pass both seconds and hours confirmation will not be discovered until analysis is completed at SDAS. Owing to the unavoidable delay in carrying out this analysis, recovery and identification of the many new objects to be found will hardly be possible.

To exploit the potential of IRAS for detecting inner Solar System objects—especially those of low visible, but high IR brightness—appropriate software was developed. An object detected using this software may be described as a 'fast-moving object' (FMO). All sources which passed the seconds, but not the hours, confirmation tests were passed to this FMO detection software.

FMO detection software

The first selection process applied to seconds-confirmed, but hours-failed, sources was based on flux ratios. This was followed by a search for correlations between two comparable detections to provide information on the speed and direction of motion of the source.

The band I/band II and band II/band III flux ratios provide an indication of temperature, and were tested for all multiple-band, non-hours-confirmed detections. To allow for uncertainties in the PAF detector calibrations, these tests were set to pass all sources which gave indicated temperatures between 100 and 400 K. These limits were wide enough to ensure that no true inner Solar System objects were accidentally rejected. Due to source confusion near the galactic plane (which caused many fixed sources to fail hours confirmation), a galactic latitude limit was applied. Objects nearer to the galactic plane than ±5° were rejected.

One consequence of the hours-confirmation strategy (an overlap of half the array on successive orbits) is that a moving object will be observed as two separate non-hours-confirmed detections, if, after one orbit (100 min): (1) it moves more than the position errors due to detector size, and so on, involved in defining 'hours confirmation'; (2) it stays within the telescope field of view.

The minimum motion limit depends on the direction of motion and the number of bands in which the object is detected. In the in-scan direction (approximately along a line of ecliptic longitude), the detector width (for bands I and II) of 0.75 arc min and the satellite scan rate of 3.85 arc min s^{-1} allow motions of ~0.3 arc min per orbit (0.18 arc min h^{-1}) to be recognized. The cross-scan length of the band I and II detectors is 4.5 arc min, but improved resolution is obtained from the offset arrays[4]. Sources detected in more than one wavelength band therefore have more accurately defined positions: thus, smaller motions can be resolved for multiple-band sources. The smallest cross-scan motion which could be recognized was 1 arc min per orbit (0.6 arc min h^{-1}).

The maximum motion which allows the object to remain in the 30-arc min field of view of the telescope depends critically on the component of motion in the cross-scan direction. Sources may have a cross-scan component of motion in the same direction as the scan advance (prograde), of up to 45 arc min per

Table 1 Alerts for which observations were attempted

Candidate moving objects were labelled according to the Spacecraft Operating Program (SOP) during which they were detected together with a sequential number within that SOP. Thus IRAS 180-1 was the first moving object alert originating from detections in SOP 180.

orbit under certain circumstances (that is the first detection is on the trailing edge of the array; the second detection is at the leading edge of the array). For the case with retrograde motion the limit is 15 arc min, but it will normally be less.

To minimize chance pairing of sources and to restrict motions to a limit which allowed a reasonable chance of recovery using Schmidt telescopes, the FMO detection software inter-compared all non-hours confirming sources within a search box of specified size. This search box was set throughout the mission to compare all sources within 25 arc min, both in right ascension and declination. Flux comparison tests were applied to pairs of sources separated by one or two orbits which satisfied these motion criteria. To allow for observational errors and possible rotational light-curve variations, flux differences were accepted up to a factor of 6.5 (that is, two magnitudes). All pairs of sources which passed the above tests were output by the software for individual identification. This checking eliminated known asteroids and comets (by comparison with daily ephemerides) and source confusion due to extended sources, such as dark nebulae (by examination of sky survey plates). Single detections of fixed sources which had 'leaked' into the software (for example, those awaiting confirmation on subsequent scans and which had been paired by chance) were also identified at this stage. Candidate moving objects which remained unidentified were communicated, together with an estimated visual magnitude based on the IR fluxes, to cooperating observatories with wide-field cameras for optical confirmation.

The program was first run using IRAS data on 11 February 1983, and, by the end of the month, known main-belt asteroids were being identified. Altogether, 37 alerts were sent to cooperating observatories, of which 17 were not searched for due to unfavourable position, bright moon, or bad weather. The alerts for which observations were attempted are summarized in Table 1. Further details of some strong unobserved or unconfirmed candidates are given in Table 2 for the information of observers who may have exposed plates near to these objects.

IRAS comets

Six comets were discovered by IRAS: the orbital elements derived from IRAS and ground-based measurements are given in Table 3. In addition, five known comets were identified from published ephemerides; data for these are also given in Table 3. The new comets cover a range of inclinations, perihelion distances, and so on, and include both long- and short-period objects. There is a notable tendency for detection to occur at southerly latitudes, but this is more likely to be an effect of the IRAS survey strategy than an indication of the true distribution of cometary orbits. Although it will be necessary to carry out a detailed statistical study to be sure, it is not apparent on an initial examination that comets detected by IRAS have significantly different orbital characteristics from comets detected by observations in the visible.

In terms of individual characteristics, the first comet detected by IRAS (IRAS–Araki–Alcock) was notable because it passed close to the Earth shortly after its discovery, and so was studied in detail both by IRAS and by ground-based observers[5–11]. Dynamically, comets 1983j and 1983v are more interesting. These are short-period comets with inclinations to the ecliptic >45°. Only one of the previously known short-period comets passing perihelion between 1982 and the end of the century (Comet Tuttle) has an inclination of this amount[12]. In fact, Comet 1983v is the only short-period comet with an orbit nearly perpendicular to the ecliptic: it also has the shortest known period for a comet with a retrograde orbit. The question raised by these comets concerns their origin. Assuming that short-period comets are brought about by planetary capture, this can only have occurred when the comets were near the ecliptic plane. For Comet 1983j this is reasonable, because its aphelion distance is very close to the orbit of Saturn.

Comet 1983o was detected by IRAS on 27 July, but was not then recovered by ground-based telescopes. A subsequent IRAS detection on 1 September was recognized, from its IR fluxes, as being a second identification of the same object. An ephemeris based on the two positional measurements was then used to recover the comet from the ground[13]. This seems to be the first occasion on which a comet has been discovered and an ephemeris allowing recovery calculated purely on the basis of satellite observations.

The visual magnitude limit for a comet to be detected by IRAS is estimated to be ≈17. This is based particularly on observations of 1983f and 1983o, which were found to be close to the FMO detection threshold. However, the magnitude limit

Table 2 Strong unobserved or unconfirmed candidates

Several known comets reaching perihelion in 1983, which may have been detectable by FMO software, were not recovered. These are: Comet Gunn 1969 II; Comet Johnson 1949 II; Comet Taylor 1961 I; Comet Schwassman–Wachmann (1) 1925 II; Comet Bowell–Skiff 1983c*; Comet Shoemaker 1983p; Comet Russell (3) 1983i; Comet Sugano–Saigusa–Fujikawa 1983e. The non-detections are attributable either to motions below the FMO detection threshold, or to the faintness of the object. The exception is Comet 1983e, which was both fast moving and very extended. In this instance, the comet may not have been scanned by IRAS, or have been recognised as a point source.

* Detected as a moving hours-confirmed source at SDAS.

obviously depends on the gas-to-dust ratio, as the IR emission comes from the heated dust. A dusty comet could be detected at somewhat fainter visible magnitudes, whereas a mainly gaseous comet would be visually brighter than the proposed limit. As we have noted, detection of comets is limited not only by brightness, but by motion. Thus Comet 1983t was probably not detected by the FMO software. There has been some confusion on this point as an ambiguous IRAS detection led to a ground-based observation of the comet. However, this was probably a coincidence: not only was the comet of visual magnitude 18 at this time, but its motion (41 arc s h^{-1}) was then below the detection threshold of the FMO software.

There may well be other comets brighter than $M_v = 17$ with motions below 1 arc min h^{-1} in the IRAS database. These were not processed by the FMO software because they passed the hours-confirmation test. It is clearly important to determine whether they will be identifiable during the analysis of slow-moving objects at SDAS. Main-belt asteroids processed by the FMO software exhibited a range of IR flux ratios, due to their range of temperatures and to errors within the IRAS detectors. These were wide enough to encompass all the comet detections except IRAS-Araki-Alcock (whose proximity to Earth resulted in a significantly higher effective temperature). It might therefore appear that moving objects, which are recognized as essentially point sources by IRAS, cannot be separated into comets and asteroids: this has to be done by ground-based observation. In fact, the two classes of objects actually can be distinguished by examination of the unprocessed detector output. As comets are extended sources, the profile of a detection in the in-scan direction is wider than that of a point source. In the cross-scan direction, detectors adjacent to those along the nominal source track may show evidence of a signal, revealing an angular size greater than that of a single detector element. This test was successfully applied to Comet 1983f, which was the faintest of the IRAS comets.

Note that almost all moving, three-band sources detected by the FMO software were identified as known main-belt asteroids. Thus, any such source which cannot be so identified in the IRAS output has a good chance of being a comet. It should be checked for spatial extension by reference to the IRAS unprocessed data.

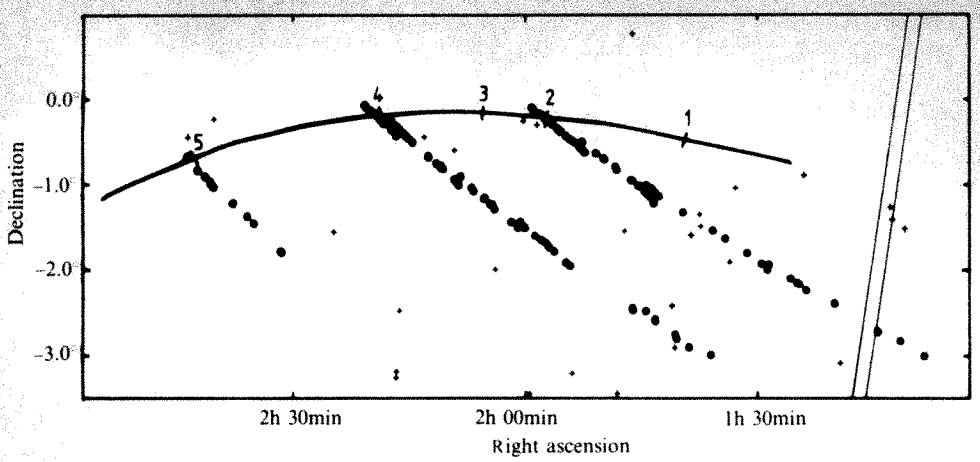

Fig. 1 Positions of non-hours-confirmed sources detected 10–17 July, 21–27 July and 8–9 August. ●, Detections of the tail of Comet Tempel 2; +, other sources. Positions of the comet on (1) 10 July, (2) 17 July, (3) 21 July, (4) 27 July, (5) 9 August, are marked along its track. A single IRAS scan track is also shown at the right-hand side of the diagram.

This should also be done for apparently spurious sources detected during IRAS additional observations: we urge IRAS AO observers to bear this possibility in mind when examining their data.

IR tail of comet Tempel-2

During the period 12–18 July, the FMO software detected about 50 faint, seconds-confirmed sources, having a signal-to-noise ratio of ~5 in the IRAS 25 μm band. These sources seemed to be related to the periodic comet Tempel-2. Figure 1 shows a sample of the detections together with the position of the Tempel-2 nucleus at the times corresponding to their detection. Note that the IRAS scan crosses the tail almost at right angles. With the ~1° day^{-1} progression of the IRAS scan, several days were required to build up a full picture of these features (see Fig. 1). That they represented sections through a continuous tail was verified during the repeat survey scans for weeks confirmation (22–27 July). These showed features in a similar sequence relative to the comet (which had, of course, moved relative to the stars during the intervening period). An examination of the raw data subsequently indicated that the tail was recorded by all band II detectors across the focal plane. Only the most sensitive of these registered a signal-to-noise ratio >5, the PAF processing threshold.

The width of the Tempel-2 tail was found to be ~4 arc min, although its angular length was ~10°. This clearly represents an unusually high aspect ratio. The position of the tail was passed to ground observers, but no optical detection was reported (although a 4 arc min tail was reported by a visual observer[14]).

No similar feature was detected for any of the other comets observed by IRAS. Analysis is under way to determine whether the detection was an effect of optical depth due to the proximity of the Earth to the comet's orbital plane, or whether it was due to an outburst of material in the days preceding the IRAS detection.

Earth-crossing asteroids

It was expected that Earth-approaching asteroids (Apollo asteroids) would dominate the objects discovered by the FMO software. However, as indicated in Table 4, only two IRAS FMO candidates have been optically confirmed as new Apollo objects. In addition, the software independently discovered Apollo asteroid 2201 Oljato, whilst another strong candidate (IRAS 487-1) was not optically recovered.

The small number of detections compared with pre-launch predictions can be attributed to a variety of factors. In particular, the predictions were based on an estimate of the sensitivity in the 12-μm band which proved overoptimistic by approximately a factor of two. In addition, the diffuse 25-μm background, especially near the ecliptic plane, made identification based only on 25-μm detections very uncertain. It should be added that, towards the end of the mission, the scan strategy was changed from coverage of lunes (areas bounded by lines of longitude 60° apart) to scans over the ecliptic poles, resulting in greater sky coverage at high ecliptic latitudes.

Detection of Earth-crossing asteroids also depends critically on their motion. Thus, Apollo asteroid 1620 Geographos was seen only once, and asteroid 1983LC escaped detection totally, because their motions were of the same order as the width of the IRAS scan, but in the opposite direction to that in which the orbital overlap advanced. This allowed them to cross the scanned region between successive IRAS orbits. Conversely, objects whose motions were approximately coincident in direction with the scan advance were detected on several successive orbits, for example 2201 Oljato (six detections), IRAS 487-1 (five detections), 1983TB (seven detections).

As shown in Table 4, the orbital elements of 1983TB are similar to the mean orbital elements of the Geminid meteors[15,16]. The implication is that 1983TB could be the progenitor of the Geminids[17], and may therefore represent a decayed, or inactive, cometary nucleus. No evidence of cometary activity was reported by ground observers, and the source appeared point-like in the IRAS data. The Geminids differ from most meteor showers in the apparently higher mean density of the particles. Hence, we may be seeing here an unusual type of meteor source.

Conclusions

The IRAS mission has provided an all-sky IR survey with a detailed pointing history. The analysis now in progress will allow an estimate to be made of the detectable population of comets

and Apollo asteroids. It is, however, possible to draw the following general conclusions from the results already obtained with the FMO programme.

(1) IRAS could detect comets having visual magnitudes <17, provided their motions exceeded ~ 1 arc min h^{-1}.

(2) The positional accuracy of IRAS detections depended on the number of bands in which an object was observed. The accuracy proved adequate for approximate ephemeris calculation, though unsuitable for accurate orbit determination.

(3) There is no evidence for a significant population of undiscovered main belt-asteroids at high ecliptic latitudes, at least amongst those having visual magnitudes brighter than 16 and motions ≥ 1 arc min h^{-1}.

(4) Asteroids and comets are both identified by PAF as point sources. The two types can, however, be distinguished by referring back to the raw data where these are available.

The success of this project would not have been possible without the support and cooperation of the IRAS team at RAL and the help of optical astronomers around the world who reacted promptly to IRAS alerts. We thank especially B. G. Marsden and D. Green of the Central Bureau for Astronomical Telegrams for their invaluable assistance. IRAS is a joint project of US NASA, the Netherlands NIVR and UK SERC. J.K.D. and S.F.G. thank SERC for financial support during this project.

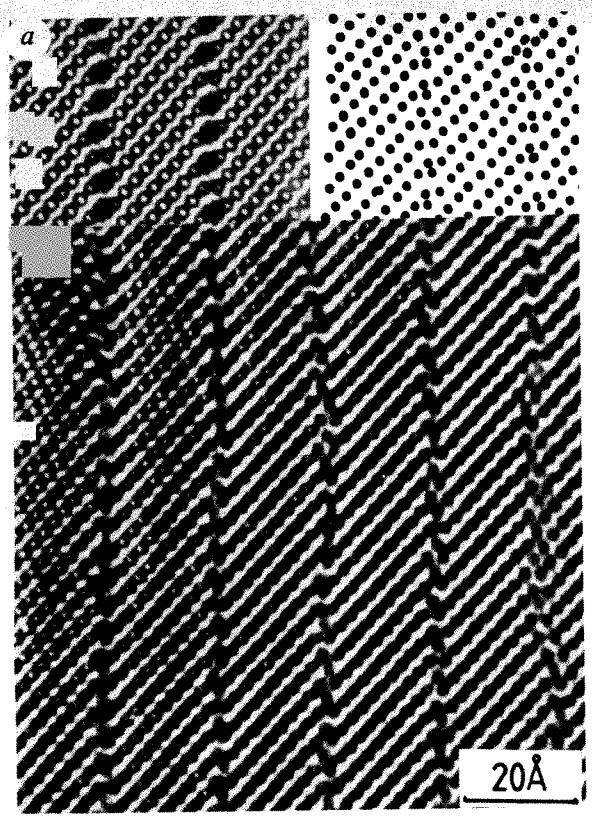
Interaction of small and extended defects in nonstoichiometric oxides

L. A. Bursill & David J. Smith

School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia and High Resolution Electron Microscope, University of Cambridge, Free School Lane, Cambridge CB2 3RQ UK

Analyses of the extrinsic and/or intrinsic nature of extended defects in nonstoichiometric titanium and tungsten oxides are made by drawing Burgers' circuits directly onto high-resolution electron micrographs. The essentially interstitial and/or vacancy nature of the small defects responsible for the phases TiO_{2-x} and WO_{3-x}, which exist above the extended defect precipitation temperature, may then be implied. Images suggesting a partial wall of anion vacancy defects have also been obtained.



CONSIDERABLE uncertainty and controversy surrounds the nature of the small defects responsible for the nonstoichiometric oxides TiO_{2-x} and WO_{3-x} (refs 1, 2). Thermodynamic studies[3,4] and physical property measurements (such as electrical conductivity[5,6]) are interpreted traditionally in terms of point defect structures; namely, singly- or doubly-ionized oxygen vacancies or cation interstitials. Mechanisms of aggregation or interaction of small defects to precipitate as extended defects have been derived for both oxide systems[7,8], but it has always seemed possible to conceive of alternative or competing mechanisms; one based essentially on charge-compensated oxygen vacancies[9,10], and one based on electrostatically neutral linear cationic interstitial defects[7,8]. We show here that whether crystallographic shear planes (CSP) grow by aggregation of interstitial and/or vacancy defects can be established by determining the extrinsic or intrinsic nature of the partial dislocation bounding the CSP, as revealed by drawing Burgers' circuits directly onto high resolution micrographs. This represents one approach to determining the nature of the small defects.

High resolution electron microscope (HREM) studies of TiO_{2-x} and WO_{3-x} have recently established structural features that were overlooked by earlier lower resolution studies. In the case of slightly-reduced rutile, TiO_{2-x} ($0 \leq x \leq 0.0035$), these include the existence of {100}-platelet defects[11] and the precipitation of pairs of CSP in slowly-cooled samples[12]. In WO_{3-x}, at least three types of extended defects have been observed: CSP[13,14], pentagonal bipyramidal columns (PC)[10,15] and hexagonal tunnels (HTB)[16]. These phenomena were all consistent with new linear interstitial cationic defect models, derived to explain the structure of the small defects in TiO_{2-x} (refs 7, 9).

Experiments

High-resolution images were obtained with the Cambridge University 600-kV HREM[17]. As this microscope has an interpretable resolution limit of better than 2 Å, cation arrangements along CSP can be read directly for appropriately focused images of sufficiently thin crystals[18]. Figures 1*a*, *b* show examples for a [111] specimen of $(Ti, Cr)O_{1.92}$ and a $[100]_{pc}$ specimen of $(W, Nb)O_{2.933}$ respectively. (Further details of specimen preparations and imaging conditions are given in ref 19. Indices without subscripts refer to rutile whereas those subscripted pc refer to pseudocubic axes of WO_{3-x}.) Disorder within the CSP is readily visible in TiO_{2-x} (Fig. 1*a*; see ref. 12 for structural interpretations) and Fig. 1*b* shows evidence for split occupancy of one double-square tunnel (labelled S), corresponding to steps in CSP structure for WO_{3-x} (work in preparation).

Many CSP terminations have been imaged for specimens of $TiO_{1.9966}$ (ref. 19) and $(W, Nb)O_{2.933}$. In each case differences in detail occurred so that it became clear that there was no unique partial dislocation structure. Thus CSP in rutile were often 'decorated' by {100} platelet defects[11,19] (Fig. 2), whereas CSP in tungsten oxides often contained pentagonal columnar

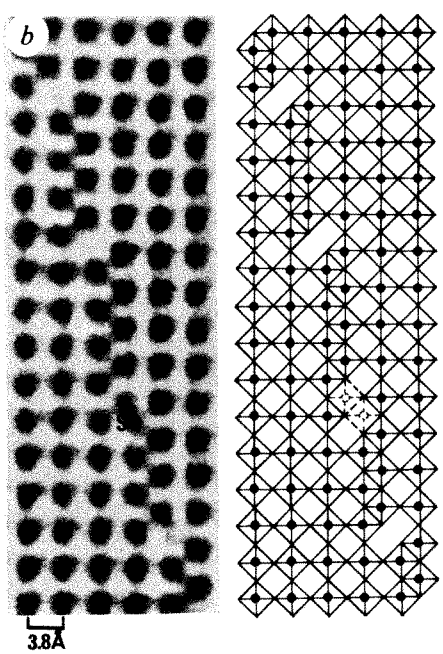


Fig. 1 *a*, 500-kV image of $(Ti, Cr)O_{1.92}$, showing slightly disordered crystallographic shear planes (CSP). Inset shows the structural model for ordered (374) CSP and the computer simulation. Note the sequence of occupied cation sites, which may be read off the image provided the disorder is not excessive. *b*, 500-kV image of $(W, Nb)O_{2.933}$ showing a segment of $(103)_{pc}$ CSP. The inset gives the octahedral representation, showing that tungsten (or Nb) cation positions are located readily by inspection of the image.

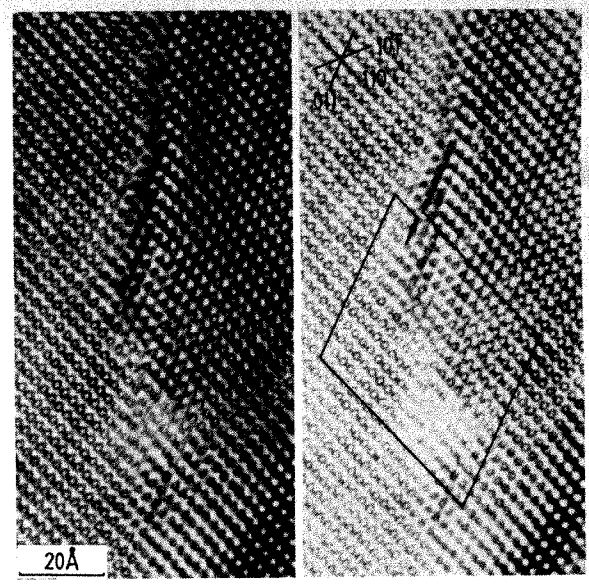

Fig. 2 500-kV image of $TiO_{1.9966}$ (reduced at 1,323 K and cooled slowly over 1 week in a dynamic vacuum of 10^{-6} torr)[11] showing termination of single (132) CSP. The inset shows Burgers' circuit analysis, with closure failure $\sim[0\frac{11}{22}]$, establishing extrinsic nature for this CSP.

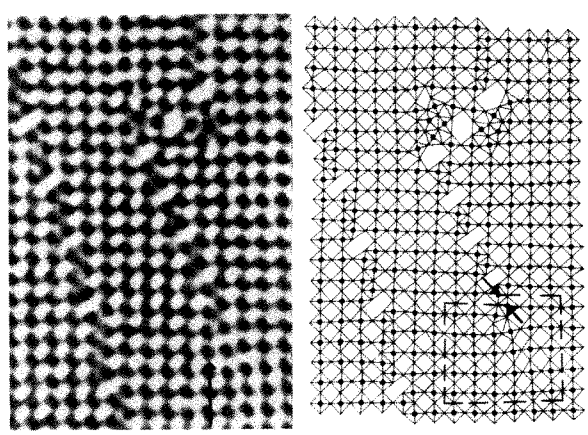

Fig. 3 500-kV image showing termination of $(103)_{pc}$ CSP within WO_3. The location of the terminating half-plane (sight along arrow) establishes the intrinsic nature of this CSP. The inset shows Burgers' circuit analysis, with closure failure $[\frac{11}{22}0]_{pc}$ (see Fig. 2).

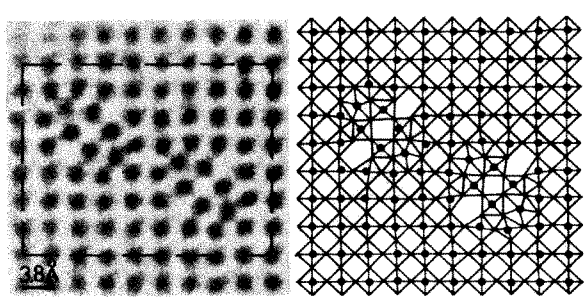

Fig. 4 500-kV image of $(W, Nb)O_{2.933}$ showing two pairs of pentagonal bipyramidal columnar defects; occupied tunnel sites are located by comparison with the structural drawing. Burgers' circuit shows zero lattice displacement.

elements within the termination (Fig. 3). These two examples have been chosen for analysis here because of their relative simplicity; further variations, with structural interpretations, are given in ref. 19.

It was surprising that, for both systems, extended defects occurred which exhibited approximately zero lattice translation, corresponding to pairs of CSP in rutile (see ref. 19) and pairs of occupied pentagonal tunnels for tungsten oxide (Fig. 4).

Burgers' circuit analyses

The geometrical operations for single CSP in TiO_{2-x} and WO_{3-x} may be written $(132)[0\frac{1}{2}\frac{\bar{1}}{2}]$ or $(100)_{pc}[\frac{1}{2}\frac{\bar{1}}{2}0]_{pc}$ for extrinsic, and $(132)[0\frac{\bar{1}}{2}\frac{1}{2}]$ or $(100)_{pc}[\frac{\bar{1}}{2}\frac{1}{2}0]_{pc}$ for intrinsic defects respectively. A convention is adopted that if the CSP has indices (hkl) and displacement $[uvw]$ then the dot product $(hkl)\cdot[uvw]$ is >0 for extrinsic and <0 for intrinsic CSP. In the case of rutile, diffrac-

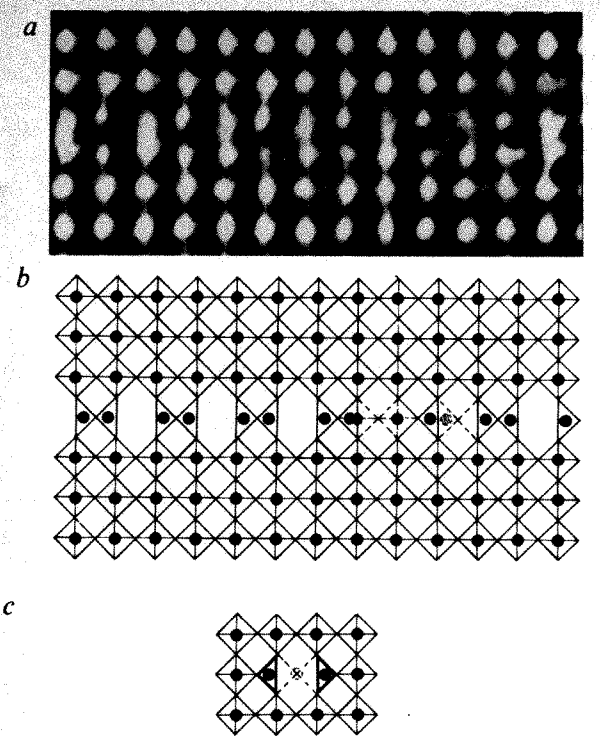

Fig. 5 500-kV image of (W, Nb)$O_{2.933}$ showing novel defect contrast in WO_3 matrix between CSP (*a*), which may be interpreted as a partial wall of oxygen vacancies aligned onto $(100)_{pc}$, premonitory to collapse and formation of a CSP (*b*). Some apparently split-tungsten atom images indicate partial emptying of oxygen sites along projection axis (indicated in *b*). *c*, A structural model for a single oxygen vacancy defect showing relaxation of two adjacent M^{5+} cations into square pyramidal coordination. The relaxation is estimated to be 20% of 3.8 Å (=0.8 Å).

tion contrast experiments gave $[0, \overline{0.45}\cdot 0.45]$, assuming intrinsic CSP[20], and it is the difference between this and the alternative extrinsic vector $[0, 0.55, \overline{0.55}]$ that may be distinguished by direct imaging of the termination. The principles of the Burgers' circuit analysis may be seen by inspection of the drawings given with Figs 2, 3. Thus, starting the Burgers' circuit in a region of perfect crystal, some distance from the defect, and returning to this vicinity, having crossed the single CSP (Figs 2, 3) or circumnavigated the CSP pairs[19] or pentagonal columns (Fig. 4), one finds that a slab of crystal having thickness $(hkl)\cdot[uvw]$ has been added for rutile (Fig. 2) but eliminated for tungsten oxide (Fig. 3) for single CSP, but there is no lattice translation for the defect pairs.

Note that the component of lattice translation parallel to the projection axis is half a lattice vector, for both CSP structures, and is zero for pentagonal columns. Otherwise it would be necessary to image each defect in at least one other projection to measure a third component of the Burgers' vector.

Discussion

It is remarkable that TiO_{2-x} and WO_{3-x} yield opposite characteristics for the terminations of single CSP, implying that the nature of the small defects should be essentially cation interstitial for TiO_{2-x} and essentially oxygen vacancy for WO_{3-x}. For TiO_{2-x} the linear small defect cationic interstitial model[7] also explains the structure and growth of CSP pairs[7,19]. Precipitation of pairs of occupied pentagonal columns in WO_{3-x} is not consistent with oxygen vacancy defects[8], but is explained readily using a linear cationic defect model[21]. Thus the Burgers' circuit shown in Fig. 4 contain two columns having occupancy –O–M–O–M..., in addition to the host WO_3 structure. On the other hand, the presence of single intrinsic CSP in WO_{3-x} implies oxygen vacancy defects.

Strong evidence for the existence of oxygen defects in WO_{3-x} was found inadvertently (Fig. 5*a*). This novel type of defect contrast was located close to the well-known CSP and PC features. Direct image interpretation on the basis of a structural drawing alone, as carried out above (see Figs 3, 4), seems justified although computer simulations will be used to provide further confirmation. Thus the occurrence of double-tunnel contrasts, aligned onto $(100)_{pc}$, with displacements of adjacent black blobs (usually tungsten ion positions), may be interpreted (Fig. 5*b*) as representing a partial wall of oxygen vacancies, accompanied by relaxation of adjacent cations (ideally Nb^{5+} ions) into pairs of adjacent square pyramidal five-coordinated sites. This gives rise to a charge-compensated oxygen vacancy model (Fig. 5*c*). (In practice, at elevated temperatures Nb^{5+} cations may be expected to become detached from the vacancies, being replaced by W^{6+}.) This last observation, together with further results (in preparation), imply that single CSP grow within WO_{3-x} by aggregation of oxygen vacancy defects, either feeding stepwise into existing CSP to be first forming partial walls of oxygen vacancies, premonitory to collapse and production of intrinsic CSP, bounded by a partial dislocation loop (see refs 21, 22).

It would be foolish to claim that in either oxide system, there is a unique CSP, or other extended defect, precipitation mechanism, or that there is only one small defect type in either non-stoichiometric phase. Certainly, in the case of rutile, there appears to be three regimes, where the small defect appears to be predominantly interstitial, predominantly vacancy, or impurity controlled, respectively[5,6,9]. To date HREM analyses have been restricted to specimens cooled from within the interstitial regime. For WO_{3-x} the present observations suggest that oxygen vacancy defects occur, but that interstitial defects may be required for precipitation of PC. It may be that the former occur predominantly on irradiation in the electron beam (see ref. 23) and that specimens cooled slowly across the phase boundary will show evidence for CSP-pair precipitation[8].

Conclusion

The extrinsic or intrinsic nature of extended defects may be determined by drawing Burgers' circuits onto HREM images. Such analyses may also yield, by implication, the nature of small defects existing within nonstoichiometric phases just before precipitation. It seems unlikely that unique and reproducible CSP partial dislocation structures occur in either TiO_{2-x} or WO_{3-x}, the structure of individual defects being dependent on the relative concentrations of different small defect types existing locally at the time of precipitation. Further attempts to obtain specimens and images from different regions spanning the non-stoichiometric phases are planned, but this will require even greater control of specimen preparation conditions than used so far, especially for WO_{3-x} where the phase limits are poorly defined[4].

Somatic recombination in a murine T-cell receptor gene

Yueh-hsiu Chien, Nicholas R. J. Gascoigne, Joshua Kavaler, Nadine E. Lee & Mark M. Davis

Department of Medical Microbiology, School of Medicine, Stanford University, Stanford, California 94305, USA

A putative T-cell receptor gene was isolated from the DNA of the helper hybridoma, 2B4. Analysis of the sequence components of this rearranged gene indicates the presence of separate variable (V), *diversity* (D) *and joining* (J) *region elements analogous to those of heavy-chain immunoglobulins. These findings further support the belief that the products of this locus are involved in antigen recognition by T cells. There is no evidence of somatic mutation between the putative germ-line and the expressed variable-region gene.*

T LYMPHOCYTES have a variety of important roles in the immune system of higher organisms, including the direct killing of virally infected cells (cytotoxic T cells) and either amplification (helper T cells) or inhibition (suppressor T cells) of the response to antigen. In order for T cells to perform these functions, they require a receptor for antigen which allows them to distinguish 'self' from 'non-self'. While the T-cell receptor appears similar to that of B cells (antibody) in that it is clonally distributed and has a wide range of specificities, it is functionally distinct in that it can only recognize antigen in association with a product of the major histocompatibility complex (MHC): the *H-2* region in the mouse and the *HLA* region in man. Particular subsets of T cells use different MHC molecules; cytotoxic T cells require class I molecules (H-2K, D, L in the mouse) and helper T cells require class II molecules (H-2A and E in the mouse). Any structural model of the T-cell receptors(s) must explain how these types of T cell can recognize antigen only in conjunction with self-MHC, yet respond strongly to MHC determinants from other individuals (alloreactivity) without previous exposure to these antigens, and how the ability to 'learn' self-MHC occurs in the thymus, also independent of antigen. There are two major schools of thought which attempt to explain these phenomena: the 'one receptor' hypotheses[1] hold that T cells recognize a complex of antigen plus MHC ('altered self') while the 'two receptor' models[2] propose separate receptors for antigen and MHC ('dual recognition'). Recent evidence from cloned T-cell lines and hybridomas strongly favours the view that the receptor(s) cannot recognize antigen or MHC independently[3-5], although there are contradictory data from other sources[6,7].
